A Mr. McIntyre, in a horticultural meeting in California, relates his experience in starting an orchard, which was very large. It was started 35 miles from any bees, so far as he knew; when his trees were only a foot high, they blossomed but he did not receive any fruit. As the trees did not bear fruit he was advised by other fruit-men and horticulturists to get bees, which he did, and his orchard bore profusely, and he said he had bees all around his orchard. Where there is a large area of orchard, clover, or blossoms of any kind, which require insects to fertilize them, Nature has not supposed a large number of insects to perform the work, hence the necessity of keeping bees. I have about four acres of strawberries. In the season of 1899 and 1900, when they were in bloom there was so few flowers for the bees, that I was unable for visits from bees and insects, they were literally covered with bees, and my berries were never so perfectly fertilized. Generally there are not many bees to be seen on the vines.

My market and money-making berries are the Warfield, fertilized with the Bedderwood. I have the plants in rows four feet apart and about two feet in the rows. I now the vines after the season is over, stir up the mulch and burn it away. Last year there is a good white squash which put 4± big loads of rye-straw on my bed; the straw made me $800. That is, I cleaned up that after paying for picking at one and one-half cents. The crop was about one quarter of a crop and without a heavy mulch I would not have had anything, it was so dry. We had no spring rain, and none whatever until I was about through picking. I never saw such a sight of blossoms, and never saw so much fruit set on vines as there was on this bed. If the good Lord had given me three times the usual rain in the spring I would have had an immense crop.

My land is a black, sandy loam, with clay subsoil, and with good rains in April I can raise a fine crop of berries, the seeds of which set so many berries, that I have more than one quarter as many as the Bedderwood. I have tried, on a small scale, a great many kinds of berries, but never any that will make the money as the two-named, Mr. Mclntyre, as well as I can learn, has raised more than one about one-half as much honey. The learned editor of the Gleanings in Bee-Culture, Mr. Ernest Root, thinks he has discovered the reason, and I am inclined to think that he is on the right track. Time will tell. To-wit, the difference in the length of bees' tongues. In measuring many tongues he finds there is a great difference in the length. In measuring the tongues from Dr. Miller's two best queens—those that produced the largest quantity of honey per colony—one measured 100 and the other 80, making the average 90. A Kentucky man sent some bees, and their tongues measured 30-100 and 21-100 and one measured 28-100. It takes long tongues to reach honey in red clover down to the sand and in many other varieties of blossoms. Mr. Root is right, the man who has a queen that will produce bees with tongues 23-100 long, or longer, uniformly, has a Klondike right at home.

Perhaps Prof. Lugger, of the State experiment farm, would help the bee-keepers of Minnesota by measuring the tongues of bees sent him for that purpose. This matter will be thoroughly tested next season, and probably decided, and if there is anything in it I would like to see some Minnesota bee-keeper win the prize.

I am often asked, Does bee-keeping pay? Mr. N. C. Alford, of Colorado, says it paid him. He kept bees for eight years and cleared $6,000, after paying for all the bees and supplies and money spent for labor and seed. He also owned 1000 acres of land and 500 head of cattle. The alfalfa fields of Colorado furnish an immense amount of bee-pasture, and Mr. Alford is not the only enterprise man who has made big money in keeping bees in Colorado. Twenty-four maiden ladies arrived at Denver on one train recently to engage in apiculture in that State.

In some localities in other States, during the past season, bee-keepers met with great loss by having their bees poisoned by those who wanted to get rid of bees. It is by no means to be laughed at, when we see the number of bees killed in bloom. This matter was thoroughly discussed, and it seems from letters received from the experiment stations in Missouri, Indiana, New York and Ohio, that such trees should not be sprayed when in bloom. Laws have been passed in some States to prevent the spraying of trees when in bloom, and bees are visiting them. Spraying just before and just after bloom seems to be sufficient. This is a matter that should be understood by the horticulturist, and apiculturist, par

Transferring Bees From Box-Hives—Pollezing Fruit.

BY G. M. DOOLITTLE.

A CORRESPONDENT says he has purchased several colonies of bees in box-hives, and wishes Doolittle to teil him the best method of transferring them to frame hives. The majority of our practical bee-keepers of the present day believe that what is known as the "Heddon plan" of transferring is the best, taking all things into consideration, so far given.

This plan is as follows:

Drive the bees from the box-hive and run them into a hive furnished with frames of wired foundation, the furnished hive to be placed on the stand the colony had occupied. A bee-fencing, while the box-hive with its comb of brood and honey, with the few adhering bees, is to be placed close beside the new hive. In 21 days after, when all the brood shall have emerged into worker-bees, drive the bees against the box-hive, drive the bees against the hive, and, after destroying the queen with this last drive, or the one in the colony driven before, according to which is the more valuable, unite the bees with those first driven out, thus getting the bees all on nice, straight combs, and in good shape to give a good yield of fine honey.

The combs are now taken out of the box-hive, the honey extracted from them, and they are rendered into wax to help in making more comb foundation.

Now, while the above is the best known plan where the combs in the box-hives are crooked or poor, and the season of the year that when the bees are securing honey from the field, yet if the combs in the box-hive are good, straight ones of the worker-size of cell, or we do not have the funds to buy nearly in the same time, before the bees have much brood or are getting honey from the fields, so that they will not draw out the foundation readily, then, decidedly, the old plan or method given in nearly all the standard works on bee-culture, is the proper one. In the above, when as good, straight worker-combs, made the wax from them into foundation, wired the frames to keep that foundation from sagging, and then "transferred" the foundation into those wired frames, with an amount of labor nearly equal to that required to transfer the original combs, all for the fun of saying we had used a plan of transferring different from that of Quinby's and Langstroth's day.

Straight worker-comb, properly transferred into a frame, after being fastened by the bees, makes just as good a frame of comb as is the one finished from foundation; and a frame properly filled with comb, without any wires in it, is just as good for all practical purposes, as is the one having wire in it, while the wire is a positive nuisance, if, from any reason, holes get in the combs from moldy pollen, mice or anything of the kind, so that we wish to put in a "patch of worker-comb to keep the bees from building in drone-comb. I do not wish to be considered cranky, but when a thing savors of more money out than profits in, I have always felt it a duty, as well as a privilege, to enter a mild protest, after which I am not to blame if any see fit to use anything recommended which may result in a financial loss.

BEES AND FRUIT-POLLINATION.

I have read twice the article by Thaddeus Smith, on pages 279 and 280, and the second reading only emphasized the impression of the first, which is, that he says, "I am set for the defense of facts," it seems entirely to ignore them or else is wholly ignorant of many things along the lines of which he is writing, that have transpired during the past. I will take space to speak of only two or three.

He wholly ignores those experiments made by Gregory, of Massachusetts, the great squash-grower, wherein he proved positively that not a single squash could be raised where insects were excluded from the female blossoms of that plant. And yet all Mr. Gregory did was to place netting which would have admitted millions of those "infini-esimal particles of pollen which Smith tells us are the ones which float in the air and do the work of fertilization, those without the aid of insects. If the pollinators were only stirred up with a stick, or by a breeze created by the bees' wings, in which case bees and insects may help a little.

Then he ignores the Wenham episode, which, through jealousy, excluded all the bees from that township, during which exclusion fruit was nearly if not entirely lost. The bees, no doubt, are the cause of the loss.

And he can not have forgotten the importation of our humble-bees into the continent of Australia, at a cost of thousands of dollars, after which importation clover seed obtained in fair quantities, when none before perfected. And with these little facts within easy reach of his understanding—

That "it will not do to fly about, and such claim "is all conjecture based upon preconceived theory." I believe that Mr. Gregory and history are as unimpeachable witnesses as any which Peter Island can produce.

I do not care to notice Mr. Smith's trying to "hold me up to ridicule," for any intelligent reader would know from the drift of my article in the March 14 American Bee Journal, that only nectar-bearing insects were intended, where I said insects of the "order of the bee," and another up to ridicule does not count anything in an argument.

Swarms Selecting a Location—Historical.

BY A. P. RAYMOND.

A KNOTTY problem has been discussed in the American Bee Journal, regarding the time when swarms select their future home, whether before or after emerging from the parent colony. There are many questions pertaining to bees that, at the present day, we can answer with absolute certainty. There are more, perhaps, that we have been guessing at for many, many years, and as far as we can see, regarding them as were our grandfathers, 100 years ago.

The above question is one of those "stickers" that I think will never be solved until some bee has been educated to talk and tell us the facts and figures. After reading "By the Winkie's" ideas on this subject, I thought I would consult John M. Weeks, whose work, published in 1836, I have in my library, and I found that he was probably as near the truth regarding this matter as we are to-day, after a lapse of some 64 years.

Prof. Cook thinks (page 530-1900) that their future tene-ment is selected by the bees before swarming, but after issuing; they first cluster and wait until the queen, he says, "is at hand," and then "winkie's" ideas on this subject, I thought I would consult John M. Weeks, whose work, published in 1836, I have in my library, and I found that he was probably as near the truth regarding this matter as we are to-day, after a lapse of some 64 years. After reading "By the Winkie's" ideas on this subject, I thought I would consult John M. Weeks, whose work, published in 1836, I have in my library, and I found that he was probably as near the truth regarding this matter as we are to-day, after a lapse of some 64 years.
Let us give it up and admit that we do not know a thing about it.

By the way, speaking of John M. Weeks, few living apiarists know that such a bee-keeper and author ever existed, and yet I think he should have a place in history alongside of Father Langstroth and Moses Quinby. He began keeping bees about the year 1800 in Salisbury, Vermont, and struggled along with log-gums and straw-skeps with varying success until somewhere along the line the beginning of his 80th year he thereupon patented a hive which was, in the matter of convenience, far in advance of anything before in use.

In 1836 he published a treatise on bees and their management—a very meagre and probably very widely distributed, for two reasons: First, meagre transportation and advertising facilities; and second, the work was unpopular, because the author did not accept any of the then prevalent theories in connection with bees prevalent at that period, but gave them solid facts, which, even today, relating to bees, seem stranger than fiction.

There were no railroads in Vermont at that time, and it was 13 years afterward before the State could boast of one, in fact it had been only six or eight years since the locomotive made its first appearance on this continent, consequently the mail service was also very poor at this time.

According to Mr. Langstroth’s biography in the "A B C of Bee-Culture," this work appeared two years before (Mr. Langstroth) became the owner of his first colonies. I almost wonder that Mr. Langstroth, who was scouring the world for bee-literature at this time, never crossed across this work. As proof that he did not, I will quote from his work, page 24:

"My attention has been recently called to an article in the Ohio Cultivator for 1848, page 185, by Micajah T. Johnson, in which, after detailing some experiments, he says:

‘When there is nothing more to be done to the queen, and not having the means of destroying the drone, the killer and the moth-worms soon take possession. I believe no colony is destroyed by these...’

‘...Killer and moth worms, and the diseases to which the queens are subject. This seems to be the earliest published notice of this important fact by any American observer.'

Now hear what Mr. Weeks says, 13 years before this, on page 51:

"Large colonies, that never swarm, are never destroyed by the moth unless they lose their queen, melt down, or meet with some casualty out of the ordinary course of managing them. The colony of bees are so numerous that their combs are all kept well covered during the moths season, so that no killer can enter and deposit his eggs."

Quoting from Mr. Langstroth’s biography in "A B C":

"Mr. Langstroth at that time (1858) had never seen or heard of a book on bee-culture; but before the second year of his bee-keeping, he did meet with one, the author of which doubted the existence of a queen."

Now, Mr. Weeks not only admitted the existence of a queen, but he feared them, and had a method of his own of introducing a new one:

Mr. Quinby in his work mentions T. B. Miner as being the author of a work on bee-culture which appeared probably a very short time before his own. Without a doubt, Mr. Weeks’ work is the earliest treatise on bee-culture ever published in America, and I am convinced by his knowledge of bees, and the methods he employed in their management, that they were acquired only after years of untiring perseverance and hard study.

He seems to have done all in his power to advance and promote the interests of bee-culture—the art he loved so well; but the people were not as ready to accept the true facts as we are to-day, consequently his labor was, to a large extent, a failure, and this may explain why he did not get the management at that early day being attributed to luck, and the almost universal answer to the query, "Why, don’t you keep bees?", was, "I have tried them but they don’t do well for me."

No amount of reasoning could induce them to undertake another trial.

Considering all the obstacles that lay in his way, and the difficulties he had to overcome, I think that Mr. Weeks made a good fight, and he should not be entirely forgotten. Peace to his ashes, and all honor to the memory of W. M. Weeks.

Queenie Jeanette—The Queenie of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

Out-Apiaries—Their Management for the Prevention of Swarming.

By F. GREENER.

It does not lie within the scope of this article to advise nor to discuss ways and means to bring our colonies up to the number required, and the reasons are obvious, that at least the majority of our colonies have already attained that state of development.

The principal drawback in running out-apiaries is that the bees are apt to swarm, and that the swarms are apt to go to woods. The way to prevent this management be as such to prevent all swarming.

We might run our out-yards for extracted honey, giving plenty of room to both queen and bees, always supplying empty comb, etc.; there would then be no swarming. However, we were too busy to convert our yards, so we can find a more ready sale for it. Giving plenty of room alone does not have the desired effect, and we must adopt a different management. It would be of great advantage to have only young queens in our colonies—we would then not be troubled with swarms out of their season, which appear frequently, when colonies supersede their queens. All swarms that would appear during the regular swarming period we try to head off. We seldom have any indication of swarming this year, so much sooner than June 15.

Nearing this date we watch a few of the best colonies, and when we find them constructing queen-cells our operations must soon begin. Hives and supers must of course be gotten in readiness before this time.

About June 20—some years not till June 25—I go to the colonies most likely to swarm and take them. First I give a little smoke at the entrance, then rap on the hive. I aim to give the bees time to fill themselves with honey. The hive is now opened; it may be set to one side first and an empty hive taken in its place. This latter should contain six Langstroth frames or their equivalent, supplied with starters only. This super is placed on top over an excluder, which, however, may be taken out after a week’s time. The danger of a queen entering the super is generally past after a week, and the diver may be needed on some other hive, and may be removed.

After the bees have all filled themselves they are not apt to offer any resistance, and, without using much smoke, I now shake all the bees from their combs in front of the entrance. I have "an eye" for the season, and its condition. After she has gone in with the majority of the bees, I place an entrance-guard over the entrance. Sometimes these shaken-off swarms leave their hive after their mother has gone in, and then the last thing you want is that the entrance-guard gets out of order.

The entrance-guard is to prevent such an occurrence; it should be removed when making the next visit. The apiary is gone over in this fashion, always selecting the strongest colonies first to be manipulated or stated. A visit takes care each time.

If done as I have directed, but moderately, the section-cases on these treated colonies will fill up surprisingly, especially if we have filled the sections with comb foundation, and, unless the season continues through a very extended space of time. Even a powerful colony, given this brood from week to week, will not think of swarming—they are kept too busy taking care of the young. They become very populous and also store much
honey as the brood hatches, which may be extracted after all brood has hatched.

Should we have full sets of eggs of white honey, and a second set of drilling colonies to shake off, I practice using one set of these heavy combs instead of a hive full of empty frames. I never hive a young swarm on empty combs—not in my locality. I give either empty frames with starters or solid honey-combs. The honey in the larvae will fill up to some extent, so a second hive is needed for breeding; but of course the honey must be of good color or it will spoil the looks of the nice white clover or basswood honey the bees may be storing in the sections at the time.

Some bee-keepers advocate and practice hiving young swarms—and shaken-off combs that come under the same heading—on frames of foundation. Aside from getting perfect combs I can see no advantage in this practice. Foundation in the sections pays well, however.

In the spring—just after-aparly I take the colony that has two or three extra brood-chambers and move it to a new location; the two uppermost brood-chambers, neither containing brood enough for queen-cells, if it has not died out, will make a good queen-cell in a protected space. Of course we must be sure that the queen is in the part moved. If we have placed an excluder on, a week previous, we can be very positive where the queen is. The queen must always go to the new location with the colony. It is the desire of all colonies as well as to all colonies not working in sections.

If it should seem desirable to reinforce any of the shaken-off colonies, a hive full of brood, after it has stood over winter, is the best sweet of choice. I will take it, bees and all, and place it over an escape on top of the colony to be re-inforced.—American Bee-Keeper.

The Dzierzon Theory of Parthenogenesis—Digestion.

BY PROF. A. J. COOK.

It has always pained me to read anything reflecting upon the one of the greatest discoveries ever made in natural history, that of Dr. Dzierzon, of Germany. The thoughtful bee-keeper may wonder at this remark. He says we may all note that virgin queens lay eggs and that these prove fertile. Yet they always produce male bees and none other. Old queens also frequently become wholly drone-layer. Laying workers are exclusively drone-producers. Surely, if we think carefully upon all these facts we would not wonder that the theory of parthenogenesis in regard to the queen of the honey-brook drone bee was taken so thoughtful a bee-keeper as was the great German priest. Strange others had not made the discovery before Dzierzon did. Yet we would have supposed the circulation of the blood would have been easier of discovery. Yet it was a physical one, if physical, by Harvey is considered one of the greatest of the ever made.

It is also easy for us to prove the correctness of the Dzierzon theory. Every extensive and observant bee-keeper has had intimates in his apiary queens that have failed to mate. He has noted that these queens would lay eggs, and he has also been disgusted to note that the entire progeny were drones. Whenever we read, then, that some apistarch of an experimental turn of mind has removed the eggs from drone-cells into worker-cells, and vice versa, and in so doing has changed the sex, we have a perfect right to put a large interrogation point after all his statements. Like the matter of mating in confinement, we may well write it off as that, if true, but undoubtedly not true.

Dzierzon’s theory is a very great one, and all praise is due the great German bee-keeper.

As the readers of the bee-papers know, the Dzierzon theory has recently been called in question in over and over again by no less authorities than P. Dickel of Darmstadt. He was the editor of the Nordlinger Bienenzeitung. He holds that he experiments prove that normally all eggs were fecundated. He claims to have transferred eggs from drone to worker-cells and vice versa, to the advantage of these latter classes of bees. The reverse he also claims to have found true. It will be remembered that von Siebold and Leuckart proved by microscopic examinations that Dzierzon was right in his conclusion. Dickel understands that the great scientists is no longer to be accepted. He says truly that the sperm-cell or spermatozoon would not be seen except at a very early stage in the development of the egg, and that very likely these observers made their investigation so late that they would not have noted the sperm-cell although it may have been there at an earlier period. This is true as Dickel states, yet it is also a fact that in case of fecundation of eggs the sperm努r is destroyed in the sperm-nucleus and the starlike body known as the sperm aster. These are obvious, and their presence makes certain that a sperm cell was previously in the egg.

Recently Andrew K. Y. Dzierzon, in Anat. Anzeiger, gives the results of three years’ investigations. Weismann urges that there is no ground to doubt that von Siebold saw seminal filaments (even two to four in a single egg). Blochman, also examining microscope eggs of the honey bee, failed and these results have been confirmed later by Petrunkevitsch. These, however, von Siebold could only have seen in the freshest eggs, which were all taken from worker-cells. He has made a similar observation of the sperm aster in drones. In the stage of the first maturation spindle, the nucleus of the sperm-cells is either without radiations, or else the sperm filament has not been transformed into a sperm aster. In the stage of the second maturation spindle, the sperm cell can be recognized with certainty. In the second spindle stage, however, the radiations of the sperm aster are complete, and there is no danger of either overlooking or misinterpreting them. Petrunkevitsch sectioned one hundred and twenty-three sperm-cells, and twenty-nine of these were worker-eggs, and twenty-three showed the sperm nucleus with evident radiation. On the other hand, not a single sperm aster was found in any of the ninety-nine eggs from drone-cells. The result from the study of sections of eggs taken in the second spindle stage was still more conclusive. Of the sixty-two eggs taken from worker-cells, there was no mistake regarding the presence of the sperm aster. Weismann and Dickel, however, in handling these cells, could not state with certainty that these contained the significant radiation. As every bee-keeper knows, occasionally a worker-bee comes forth from a drone-cell. As I show in my Bee-Keepers’ Guide,” the queen adds or withholds the sperm-cell at will. She may occasionally make a mistake. As I show in my book, she often does when she first commences to lay, as we frequently find at such times, drones scattered through the brood. Weismann also says that occasionally a worker-bee may occasionally make a mistake in depositing drone-eggs is no marvel. In the case where Weismann found the sperm aster in the egg from a drone-cell, no doubt the queen made such a mistake when she laid the eggs. Weismann, after using these cells, made an examination and found the sperm aster; he concluded Weismann’s views are fully confirmed—normal eggs laid in drone-cells are not fecundated, and that those laid in worker-cells are always fecundated.

Dickel makes the observation that as soon as the queen lays these, workers alter the cell and busy themselves in some kind of manipulation. He thinks that they add saliva. In case he is correct in this observation, his conclusion that this has something to do with determining sex doesn’t hold when it is killed at the time of these third maturation spindles. These are covered at once after being laid, so that the bees can not visit them, they will not hatch even though left where the warmth of the hive would seem to make the conditions favorable. It has been suggested that in the case of eggs already lived with saliva the moisture may be prevented which would otherwise prevent their hatching. I think there is some doubt about this, but in any event the determination of sex is in no way dependent upon these eggs being left in the cell. The worker or queen workers will result; if not, we may as surely expect drones. The determination of the queen or workers is unquestionably dependent upon the quantity and quality of the cells which they work.

Dickel urges that there is a difference between drones produced by laying workers and those produced by queens, and he believes that the former are functionally imperfect. I doubt whether this is true. He says Weismann says that he sees no proof that it is so. There is, however, a slight though constant difference in the development of the eggs from the two different sources. This being true, it would not be surprising if we should find that
Questions and Answers.

Conducted by Dr. C. C. Miller, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller directly, when he will answer them here. Please do not ask the Doctor to send answers by mail—Editors.)

Drones Reared from Laying-Worker Eggs.

In examining my bees this spring, I found one queen had died during the winter, and a laying worker was busy. Will the drones produced from that laying worker be a fit specimen for a queen to mate with?

New Jersey.

Answer.—Instead of one laying worker there were probably many. As the eggs that produce drones are always unfertilized, I know no reason why the unfertilized eggs of a laying worker might not develop drones. Yet I should rather not depend upon drones reared in such an abnormal way.

Workers With Drone-Eyes.

I send you a sample of bees that have heads like drones. These bees are just from the cells. The queen is one year old that produced them. They have fertilization generally, as you will see. Just about one-third of the working force are like these. One head is all right, like others. This is something I never saw before.

Texas.

Answer.—The case is one beyond my knowledge—workers with eyes like those of drones. Are you getting up a new breed of bees with hyperactive powers of vision?

Prevention of Swarming—Other Questions.

1. We wish to increase our apiary to 200 colonies this season, and thereafter we desire to prevent a further increase. Will you give us the most practical method of the prevention of increase? We wish to know that method which is both safe and practical. We use the 10-frame, simply hinged. Would it be practical to allow the swarm to come out and hive it in the usual way in a “hiving-box” on the old stand, take the parent hive away under a tent, cut out all queen-cells, take it back to the old stand, shake out the swarm in front of the hive, and then give them plenty of super room and ventilation?

2. Our hybrids seem to be inclined to swarm more than our pure Italians. Is the hybridization generally?

3. We would ask your approval or disapproval of a ventilator bottom-board as follows: Cut a hole through the bottom-board about the center 8×10 inches. Over this hole tack wire-cloth, and underneath the wire-cloth place a frame of peptone that will close the hole or open it at will. This slide may be drawn to any extent as the heat of the hive may demand. Would such a device retard or discourage swarming? We have just constructed one such bottom-board and placed it under a populous colony. We find that, when the slide is drawn, the number of fanning bees is diminished. Our hives are on individual stands, about 12 inches from the ground. We regard this bottom-board as a perfect remedy in a case of robbing. The hive-entrance may then be closed completely, and the slide drawn to give the bees plenty of air. The colony that is doing the robbing may be served in like manner. This will stop the robbing at once.

4. Which are the better honey-gatherers, the hybrids or the pure leather-colored 3-bodied Italians from imported mothers?

North Carolina.

Answers.—1. The probability is that the bees with your plan would immediately start queen-cells and swarm you. You have better success to remove the old queen and cut out all queen-cells but one. As you wish to know a method that has succeeded, you might try this: Just before queen-cells are started, lift the old hive off the stand and put in its place a hive with foundation or starters; find the queen and put her in this empty hive; put an excluder over, and then set the old hive with its contents over the excluder.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and perhaps get interested in subscribing. We will be very glad to supply such with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

The Premiums offered this week are well worth working for. Look at them.

AMERICAN BEE JOURNAL
June 6, 1901.

 drones from laying workers were unable to furnish sperm-cells that would fertilize the eggs. That the drones from the two sources may differ would not be exceptional, as there is a wasp which has two kinds of drones. It is not known, however, whether or not these drones have a different parentage.

Artificial Parthenogenesis.

The interesting experiments of Morgan and Loeb, which show that by the addition of certain salts the unfertilized eggs of sea-urchins may be made to develop more or less completely, have attracted very general attention among biologists. Recently, some further experiments by Pieri and Winkler have been made in somewhat the same direction. These scientists took the sperm, shook the same up in either sea or distilled water then filtered it and allowed the filtered sperm to fertilize unfertilized eggs. As a check, other unfertilized eggs were allowed to mature and treated the same way, except the decocation from the sperm was withheld. Many of the eggs to which the sperm extract had been added, partially developed, which was a result of none of the others. It was found that the sperm extract made in sea-water was more efficient than that made in the distilled water. To any one who has studied marine organisms, this is no surprise. These experiments are an interesting testing of bee-keepers. It would seem that in certain cases other stimuli than sperm-cells may induce the commencement at least of development. How it is that the drone-eggs develop without any stimulus at all is still a mystery which possibly may never be solved.

What is Digestion?

I am surprised at what the Editor states in the opening paragraph on page 361 that Dr. H. B. Cowan has no doubt about my criticism of his definition of digestion. I doubt if Mr. Cowan claims to be a physiologist. He quotes in giving his definition of digestion. He certainly quoted from a very able physiologist. Mr. Cowan, however, that this physiologist and no other would defend the definition. In all our physiologies we find a chapter set apart for the discussion of the subject of digestion. This chapter follows itself to the explanation of how food is fitted to be absorbed, and not to be excreted as debris and the like. Digestion is done partly in the stomach and completed in the intestines. In the stomach the gastric juice is the agent of this digestion, and the proteids, like the albumins of the food elements, are affected. These are changed into peptone—a substance which differs from all other albuminoids in being very osmotic. Other nitrogenous substances will not dialize, that is, they will not pass through the tissue membranes. Digestion is to change substances so that they may pass through and escape from the stomach into the blood. In the intestines, starch, sugar, and the fats, and possibly protoplasm, are digested in the stomach, are digested. The agent in this work is the enzyme diastase, which has three distinct substances, one of which digests the starch, one the fats, and the other, the proteins. This, then, is digestion.

Assimilation is quite a different thing. Another term for this is anabolism or constructive metabolism. This work goes on everywhere in the body. It is the changing of the nutritive elements into tissue and is the direct work of the cells which are found in all the tissues of the body. Where anabolism is very active, there the cells are very numerous, as seen in brain and muscle. Where the constructive metabolism is less active, there the cells are less abundant, as noted in bone and cartilage.

If you will consult any physiology, or inquire of any of our leading physiologists, he will no longer remain in doubt regarding the correct definition of digestion. True, our dictionaries do speak of assimilation, as though it might be akin to digestion. Physiologists do not put it in this sense. Los Angeles Co., Calif.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and perhaps get interested in subscribing. We will be very glad to supply such with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

The Premiums offered this week are well worth working for. Look at them.
2. Perhaps so; but there is not much difference.
3. Anything that allows entrance for more fresh air is a help toward prevention of swarming, but the same end would be more easily and more fully attained by raising the hive on four blocks.
4. Some of the hybrids will be better, and some not so good. The pure stock will be more uniform and more permanent in character. The pure stock is better to breed from, and will not run out so easily as the hybrids.

The Afterthought.

The "Old Reliable" seen through New and Unreliable Glasses.

By E. E. HASTY, Sta. B Rural, Toledo, O.

TALKING BEES 400 B. C.

One would say that every intelligent bee-man, ancient as well as modern, knew that it took honey to rear drones, as well as more of it to feed them after they were reared. The two different sizes of comb-cells in the hive are too common to be ignored except by pronounced dumbbellers, and it's easy to conclude drones too big to be reared in worker-cells. I would say then that perhaps it's not quite certain that Socrates knew of apiculturists who habitually practiced producing drones by creating drones by doing it, but I may have been not much more than a dream of his active mind, that if he kept bees he would save honey by cutting out drone-comb could be got at. Drone-comb is not used in the modern hive. All the same, it is interesting to hear a man talk bee-manipulation correctly four centuries before Christ. Page 254.

MORE ANENT THE SCORE-CARD.

Mr. Greiner, on page 262, laudably tries to fix things so judges of bees at fairs can not ignore the drones. He hardly gets there. Drones will still be mostly ignored, except in the special item. Suppose we change:

Color and markings of workers and drones.
Size of workers and drones.

and make it:

Color, markings and sizes of workers (10-10-16) * 35
Color, markings and sizes of drones (5-5-5) * 15

KEEPING YOUNG QUEENS CONTINUALLY.

The reform chieftain of keeping young queens continually in every hive runs against quite a "hesitate," against two hesitants, in fact, when Doolittle and J. B. Hall both emphatically denounce it. But if you do remove old queens for that purpose, be sure and destroy all cells capped at five days. Page 265.

HAVING SWARMS A LA GERHING.

And so Teacher Gehring would have his class hive bees by placing swarm and limb carefully in front of the entrance, as close as possible, and then blissfully watch results. I would respectfully put in a pretty strong protest. No doubt that succeeds nicely oftentimes; but, if I am right, a large percentage of swarms will refuse to move in as they ought—will just remain in a provoking-to-patience pile partly on the front of the hive and partly on the limb. When the same falls a member of the department, when it's just as easy to succeed all the time? I don't say you can always succeed in making them stay, but you can practically always succeed in making them run in. The fever does not die down in the department. With a big pot-spoon dose the hive—small doses and often. After awhile increase the dose, and anon fall to shaking instead of spooning. But keep most of the bees on the limb until they are running in lively. Most important of all, keep poking the entrance clear as often as it threatens to get blocked up. Waiting for stationary bees to start up is mostly a humbug. Make 'em "git fudder" right straight along. To some extent, and with due moderation, the smoker can be used to hustle them; but too much of it makes them fly badly. A brush of green twigs, to whip them and sweep them and stroke their backs, is better. And always smoke a cluster of bees gently just what you can without making them fly! before you do anything with them. Just about as bad practice to manipulate swarms without smoke as it would be to open hives without smoke. Both can often be done; but what's the sense of it? Our smoker dog doesn't charge anything for barking, and why should we bark ourselves—or go barkless, with three thousand thrusts thrust through our bark? Took me about half my bee-keeping life to get this much of horse-sense through my noodle.

GIVING CELLAR-BEES A FLIGHT.

Whether it is profitable or unprofitable to give cellarbees a winter flight is an important question. It is not easy by writing it. It would seem to me that the most profitable, My impression is that the heavy old chaps are mostly in the negative. May I be counted wrong. F. W. Hall's experience, page 268, seems quite decidedly in the affirmative—This quite healthy Irish bull I'll rest a bit from my afterthinking.

The Home Circle.

Conducted by Prof. R. J. COOK, Claremont, Cali.

SOUL-GROWTH FROM READING.

There was one advantage—the greatest one—which comes from reading that space crowded out of our last "chat" in the Home Circle is to refer to the moral uplift—the soulculture. We all agree that valuable as is bodily vigor, and desirable as it is mental growth and power, both pale before spiritual development and influence. The outcome of Samson's colossal muscle was to pull down; Shakespeare's incomparable mental grasp which so enriches our literature and quickens thought, did not lift the whole world to a higher plane. Christ's life, which touched the spiritual that is in man, raised the whole world to better thought and purpose, and the transcendent glory of any soul to be able to lift spiritually a brother soul. It is the most blessed gift that any of us can receive, to gain inspiration towards a more Christlike life. The reading of good books is the mightiest force in moral development and spiritual uplift. May I speak of our own magazine? We have about 200 students. A majority of these (61 gentlemen and 42 ladies) are engaged in voluntary Bible study. Many of these not only meet with one of their number, selected for special fitness as leader, for an hour each week, but all study the lesson for a half-hour each day, many taking the time just before breakfast. I believe that there is no one thing that promises more for the real success of our College than doing this fact—nothing that so surely bespeaks a useful future for our students.

To spend an hour each day in close mental touch with Elijah, with Paul, with Christ, gives an equipment for life that is beyond estimation. The inspiration that comes from reading good books secures to the world such nobility of soul as was in Lincoln; such purity, sweetness, and such wealth of vital, moving spiritual force, as came to us in Longfellow and Whitman.

Soul-culture is the richest adornment that any person can possess. Soul-culture makes a great people, a worthy nationality. Soul-culture alone can rightly solve the China and Philippine problems. The reading and study of good books with this friendly inspiration with the good culture. Mr. Cogshall, none of us can overestimate the value that ever comes from the reading and study of our best literature. Whatever we do, let us not neglect the matter of reading in the home circle.

BOOK AND MAGAZINE CLUBS.

It is good to have several of our best books, magazines, and papers—more than many of us can afford to subscribe for. May I tell how we manage this of like the daily papers, which usually takes about ten minutes of my attention each noon-time. I cut the price in two by taking it with my next neighbor. Do all in our home circles know how much they lose by not joining the good club with the good neighbors? We all have the very best neighbors in the world. Many of us do not know it because we do not know them.

To digress: Three of my neighbors and I own a cow together. Such friendly partnerships make a pleasanter neighborhood atmosphere, and I believe brighter home circles. Eight of us neighbors each take a magazine. Thus, we have the Century, Atlantic, Scribner, Popular Science Monthly,
Harper's, The Forum, North American Review, and an art magazine. These are passed each week, and each one has its magazine to keep in the end. I take and keep one magazine. I have the reading, or opportunity to read, eight of our best magazines. I feel rich in this arrangement, and I am glad to suggest that many of our home circles enrich themselves in some such way.

Our book club is another of our neighborhood co-operative institutions, which is now several years of age. This has a still larger range. Eighteen of our neighborhood "home circles" profit by this admirable arrangement. We all wish to see, possibly to read, surely "to thumb over," all the best books of the year. We each pay $1.50. This secures 18 books. We all unite in securing the volumes, and as we are all alert during the year, we are likely to make a good selection. We rarely secure a book that we regret later to have purchased. There are one or two such each year. We each keep a book two weeks, and on last date the day we receive it we sell each day that a book is kept beyond the specified time requires a fine of 5 cents. At the close of the circuit the books are sold to the members by auction, and always bring in more than half cost.

I recommend this, or some kindred plan, to all our home circles. It is very popular, and deserving so, with us. I presume I read about one-fourth of the books, and "thumb over" all of them. Mrs. Cook reads many more, and daughter Bertha some more than do I. Thus we get as a family quite an insight into the best that is written in America and England each year.

Anything that incites those in our American home circles to read more and more thoughtfully the best books and papers, should receive the fostering care of all of us. May not our bee-keepers profit by something like our magazine plan? There is always something in each of the bee-papers that is valuable to each of us. There are articles in each, and some number of each, that some of us do not care for at the time. To have them all would be a signal gain. In almost every neighborhood are there not five bee-keepers that get mail at a single post-office? In such case, five magazines or journals could be taken, and by a convenient exchange all have all. If such an arrangement could be generally carried out, can any one doubt but that it would be a substantial gain to our industry? When any one reads, and so handles his business more wisely, all are gainers. The slowly, unlettered bee-keeper, or even a child, that desires to purchase the book. The up-to-date, thoroughly-read bee-keeper advances the market, as all first-class products are sure to raise prices.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

HOWARD M. MELBEE,
HONEYVILLE, O.

This Cut is the Full Size of the Knife.

When ordering, be sure to say just what and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made of a strip of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, drone, and Workers, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are made of first-class English spring-steel, and the handles are plated with the finest English plated steel. The bolsters are made of German silver, and will never rust or corrode. The rivets are plated steel; the linings are plated brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a lifetime, with proper usage.

The best good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the knife may try to live on; otherwise it will be destroyed, and the chance is you will not see it. A good friend of the bee-keeper, or anyone else who is interested in bees, would please have his or her name and address on the handle of the "Novelty Knife". It is a good knife, a good friend of the bee-keeper, and yourself, and the greatest advertisement you can have for bees.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side? The accompanying cut gives a faint idea, but cannot convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to get this Valuable Knife.—We send it postpaid for $1.25, or give it as a Premium to the one sending as $1.00 to NEW SUBSCRIBERS to the Bee Journal (with $3.00). We will club the Novelty Knife and the Bee Journal for one year, both for $2.50.

GEORGE W. YORK & CO.
144 & 146 Erie Street, CHICAGO, ILL.

COMMITING SCRIPTURES TO MEMORY.

My fortunate boyhood's home circle was richer, better, for hearing the Bible read each morning. I would not have had that part of my early culture omitted for a fortune in what the world calls riches. I, to-day, can hear the words and comments of my dear father, though he has been dead for years. These memories are a priceless legacy. I could not deny my children what had been so precious to me. So I have always read daily from the "Book of Books." I have often wondered if my words read, and my comments, would be such a benediction to my children as were my father's to me. Some parts of the dear Old Book are so incomparably precious that we have learned them by heart. Thus we have the Ten Commandments, many verses from Isaiah, the 1st, 2d, 8th, 19th, 23d, 24th, 121st, and 117th Psalms, the Beatitudes, Romans 12th, and 1st Corinthians 13th, etc. We often, instead of reading, repeat them. It is a blessed help on the way to success with bees.

The book we mail for $1.25, or club it with the American Bee Journal for one year—both for $1.75; or, we mail the book free to premium for sending us THREE NEW subscribers to the Bee Journal for one year, with $3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.
144 & 146 Erie Street, CHICAGO, ILL.
Farm Wagon Economy.

The economy of this proposition is not all found in the variable price of the wagon itself, but in the great amount of labor it will save, and its great durability. The Electric Wheel Co., who make this Electric Handy Wagon and many famous Electric Wheels, have solved the problem of a successful and durable low-down wagon at a reasonable price.

A Report from Massachusetts.

This is more of a market-gardening country than anything else, with dairying as a sideline. There is no buckwheat raised to speak of, and very little white flax. About 50 colonies, I should judge, are kept within a radius of two miles from here. Are "kept," I say, but most of them keep themselves. They are in box-hives owned by people who never saw a bee-paper, and would not look at one if they could, because their fathers never did. In extra-good years they sometimes get a little surplus honey, but in poor years their bees starve. I find it a very healthy colony in a new hive for $2.50 last spring (hybrids, I should think), from which I took 29 pounds of fine comb honey. The colonies were very white and well filled out, but the honey was rather dark, almost of a greenish color, but very thick. I do not know what it could have been gathered from. The bees did not swarm last year, but will probably do so this year, and I hope it is just a bad year. They have wintered well on the summer stands.

Mrs. E. C. Fox.

The Rural Californian.

Tells all about Bees in California. The yields and Price of Honey; the Pasturage and Nectar-Producing Plants; the Bee-Ranches and how they are conducted. In fact the entire field is fully covered by an expert bee-man. Besides the paper also the best articles on California Agriculture and Horticulture. $1.00 per year; 6 months, 50 cents. Sample copies, 10 cents.

reared from the old reliable Leather-Colored stock by the latest methods. I keep colonies of Italians to select my breeders from, and breed from our very best honey-gatherers. Untested, 50¢ each; 1 dozen, $5.00. Safe arrival. Send for price-list. Address, W. J. FOREHAND.

FORT DEPOT, ALA.

A Foster Stylographic Pen...

This pen consists of a hard rubber nib, the point of which is a round point, and writes as smoothly as a lead-pen. The nibs of the pen are made of platinum, alloyed with iridium—substances of great gravity which are not affected by the action of any kind of ink. They hold sufficient ink to write 10,000 words, and do not leak or blot.

As they make a line of uniform width at all times they are unequaled for ruling purposes.

Pens are furnished in neat paper boxes. Each pen is accompanied with full directions, filler and cleaner.

Best Manipulating Pen on the Market. 19,000 Postmasters use this kind of a pen. The Editor of the American Bee Journal uses the "Foster." You should have one also.

How to Get a "Foster" FREE...

Send two NEW SUBSCRIPTIONS to the American Bee Journal for one year, with 50¢, or send 80¢ for the Pen and your own subscription to the American Bee Journal for one year: or for $1.25 we will mail the pen alone.

Red Clover Queens

LONG-TONGUED BEES ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with $2; or, one Tested Queen free as a premium for sending us FOUR new subscribers with $4.00).

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke.

They stored red clover honey last season.

Orders for these fine “long-reach” queens will be filled in rotation—“first come, first served”—beginning about June 10th. It is expected that orders can be filled quite promptly, as a large number of nuclei will be run. All queens will be guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, $1.00 each; Tested, $2.00 each. Send all orders to

GEORGE W. YORK & CO.,
144 & 146 Erie St., CHICAGO, ILL.

they will worry and gnaw, and if there is a possible chance they will rush out and cause trouble. I remove them regardless of strength; some of the hives may be full of bees, but there will be no danger of crossing, or crossing.

The most important thing to be considered in moving bees is which way the combs shall be plied—toward the brood or acrosswise.

Many of the readers will remember our good old friend and bee-master, J. H. Townley, who in the early ’80’s gave us, as well as many others, our first lessons in keekeeping, and who advocated placing the combs lengthwise. But after years of practical experience on all kinds of roads of billy, stony, up-and-down, trotting the horses, etc., I find that combs placed crosswise is the safest method. There are more or less rats, sticks, stones, etc., on any road, while up or down hill one always walks a horse or team.

Prospects Good.

Bees are doing well. Clover is plentiful. Prospects in general are good.

Stephenson Co., Ill., May 16.

Bees Working on Dandelion Bloom.

Our bees have been doing very well the past two weeks on dandelion and other bloom, some colonies having 50 or 60 pounds of surplus honey in the extracting combs. A northeast wind and rain prevails at this time, while the honey is evaporating in the traditional. If the weather does not end in a killing frost there will no doubt be an abundant flow of raspberry and other honey as the weather is warm enough.

H. W. CORNELISON.

Washburn Co., Wis., May 23.

A North Carolina Report.

We have an apiary situated in eastern North Carolina, which is being run for comb honey. Last year the spring opened with 75 colonies in very poor condition, owing to the fall bloom being cut off by storm the August 20th. Last year was one of best honey-years ever known here, and our 75 weak colonies built up and gave us 800 pound sections of honey. About three-fourths of this was white honey.

We wintered our bees last winter in single-wall hives with the top removed, with the loss of a single colpy, except that two were found queenless. This brought this out this spring, with 122 colonies. While this was the smallest number of colonies of any kind in condition, April was a cold, wet month, and the bees pulled through under difficulties.

The apiary is situated in a pine thicket bordering on a farm. The trees are 50 or 60 feet high. Hence we have to clip our queen until we may be able to control the swarms. We have had 24 swarms up to date.

Occasionally a queen will emerge with her wings, which is the result of superseding. One such came out today and lit in the top of a pine 50 feet high. We were anxious to bring her down, fearing other swarms might join her. We tried jarring the tree with an ax, thinking that she would get off of sprad, and alight lower; but she resisted our efforts until we despaired of being able to capture her. We then shot at her, as one would an "outlaw," five shots from a Winchester repeating shot-gun brought her to the ground, together with many of her followers.

BAXTER & FARNELL.

Pauline Co., N. C., May 18.

A Colorado Lady's Experience.

I bought 16 colonies of bees and united to 13, a year ago last fall. This was too large a start, according to all the advice I could get, but I wanted to go in that deep. I spent about $80 on bees, new hives, etc., and last year I spent $100 on all sorts of supplies. The bees have yielded honey enough to pay for themselves and the cost of keeping them. I now have 36 colonies in fine condition, so I think it has been a success.

I have read so many bee papers and books that I am just bursting with information, but

when confronted by a live bee, or a practical situation; I feel real ignorant and helpless. I had such a queer experience in introducing queens last year. There was no pasteboard over the cage, and there was no queen, so I knew they would not lose their grip, and I had an imperfect queen. I didn't know that. either. None time before, I knew their queen was dead, and gave them a frame of eggs, which were 'too old, I think. I was assailed by the bees, and I was in such an ill humor that I had not the time to notice the change. Then I returned again, and I was in such a state of mind that I was not able to discover that neither queen had been replaced! I waited three days longer, and then the bees were not kicking about. I found out then for the first time that they had a drone queen.

Looking in the other hive, I found the queen still imprisoned, and so I let her out myself. Two weeks later both hives were full of young queenless drones, and I was afraid the quantity! Neither colony was worth requeening, apparently, but I wanted to try an experiment. Then I was very anxious for fear the brood would chill and the queens wouldn't go through the winter, for I saw they were weak. I fed them and put them up snug and left them. Now they are running with bees.

Imprisonment didn't seem to injure those queens. I am afraid I will lose track of them when they swarm. I have never tried clipping, but do not think they are Miss Josephine Field,

Las Animas Co., Colo., May 12.

The Uses of Honey.

Mr. Herman Cook, of Wyoming Co., Pa., sends us the following, taken from the New York Tribune, contributed by J. F., of Preston, Conn.:

The ancient regarded honey as a celestial food, and they used it at all religious ceremonies. The Egyptians used it as a remedy for various diseases. To judge from the Bible, honey was considered as delicious and as pellable as milk and flour, and it served them as an excellent medicine for the cough, asthma, and fever, etc. For the Arabians, honey is of great importance, as it is known in the Koran by the story of the man who one day asked a bee what to do for his brother, who was suffering great pain, and about to die. The prophet prescribed honey, and the bee answered him. After a short time, however, the man returned and told Mahomet that the remedy, instead of alleviating the evil, only made it worse. But the prophet answered, "Go home and continue to give honey to your brother, for tied speaks the truth, and your brother's body has lied." And the man returned prepared after a continued use of the remedy.

The ancient Greeks used honey as a means to prolong life. Pythagoras lived only on honey in order to keep healthy his body as well as his mind. Other examples are those of Democritus, who lived 154 years, and Anacreon, who died at the age of 115. Both were very fond of honey, and consumed it in various mixture.

Therapeutically, honey is much employed in diseases of the mouth. It is known that these delicious properties have been discovered only after the application of honey in combination with alun or borax. When children are teething, it is found they are very relieved with a decoction of marshmallow (the root of Althaea officinalis), or saffron with honey. For pains in the throat, a mixture of honey and lemon juice is an excellent remedy. As curatives are further known the thymus, eucalyptus (tublar and honey), and the salutary wine (cherry, knapweed, white wine and honey). Also the application of diluted honey to burns, blister; (in this case the honey is combined

"THE GARDEN BOOK."

A NEW BOOK ON GARDENING,

BY T. GREENE.

This is a new book on gardening. Mr. Greiner has for 30 years been practicing and practising the gospel of good gardening with marked success, and I think he has now finished his work. Thirty years of actual soil-contact by a man who loves his work and follows it in all its details has not failed to make him a great gardener when it comes to teaching others. In the "Garden Book" he writes in simple language about things that will work in a most entertaining and instructive manner.

The man who has a garden, large or small, and the man who intends to have one, will be equally interested and profited by a study of its pages. It is one of those books which inspire its readers to reach out for better results through more thorough work, and is in line with the previous writings of Mr. Greiner, which have done some real work in the garden interests of the United States. The book is handily printed, price is one dollar, and comes in a handsome paper, containing 12 practical illustrations. It is for present reading and right for every-day reference.

Prices, postpaid, 50 cents; or with a year's sub-

inscription to the American Bee Journal, both for $3.00; or we will mail it free as a premium for sending one NEW SUBSCRIBER to the Bee Journal for a year with FREE.

GEORGE W. YORK & CO.

CHICAGO, ILL.

Ten Days on Trial.—In the past several years certain manufacturers and others, with that knowledge and understanding of the honey-producers, have been sending out all sorts of things to the farmer to be tried by him and paid for only after he is convinced of their merit and satisfied with the bargain. So far as we know, however, the Kalamazoo Carriage and Harness Co., of Kalamazoo, Mich., is the first firm in the United States to make such tests. The plan is to send articles which appear in their catalog to anybody, anywhere, on 10 days free trial. The purchaser or-
derers the vehicle he may wish, and when it is shipped, he goes to the railroad station, hires a wagon, and drives in the car in any legitimate way and subject to any test arising.

If at the end of that time he is satisfied with the job, he simply pays the catalog price for it. If not, he ships it back to the factory,

This appeals to us as being about as fair and open a method of doing business as it is possible to imagine, and certainly a most gracious compliment to the beekeepers and the farmers of our country. It gives them the oppor-
tunity to see for themselves what they are buying and to test it in every way before being obliged to pay for it. Certainly the manufac-
turers, who will offer their goods to people on such liberal terms, have unbiased confidence in the value of their wares. And this is exactly what we want under these conditions, that the Kalamazoo Carriage and Harness Co. made only first-class vehicles, and trimmed and finished them only in the most splendid and enduring manner. Our readers who are in need of a vehicle or hardware of any kind should write them at once for illustrated descriptive catalog. They mail it free.

Please mention the American Bee Jour-

nal when writing.
with oil of turpentine, inflammations, and in many cases of veterinary practice, are almost generally known.

To preserve the complexion there is nothing better than honey-baths, which, a hundred years ago, were much in use among the ladies of the stage, and have to-day again come into vogue in Paris.

Spring Feeding in the Fall.

The Canadian Bee Journal reports that very practical beekeeper, J. B. Hali, as saying:

"As far as spring feeding is concerned I am a lazy man, and I have found it is better to give the spring feed in the month of September. I do have a few colonies that have advorved in the past, never open your colonies until the fruit blossoms, unless there is something wrong with the bees. If you want to know their strength, and can not tell by the noise they make, tip up the hive and look underneath—do not break the quills. You may not know the difference of a crop of honey or no honey. You open them in the spring to see if they are queenless—what good can you do them if they are queenless? Let them be.

Money Not the Highest Success.

W. A. Gilstrap utters some good sense in the Bee-Keeper's Review when he says:

"Many make more than a living at home, mainly from bees, who could make more money to scatter their time and business all over the country, as they would have less of life's real success than at present.

"To illustrate, you can find places, isolated perhaps, where you can make more money with systems of outapiaries than you are doing at present; but you would necessarily have to be away from home more, would be working away from your family, and would not yield as much self, than your present capacity. To make the suggested change would be very unwise.

In-Breeding.

The opinion is commonly held that without occasional introduction of fresh blood one's stock will run out, and that continued in-breeding means final decay. Under usual circumstances the opinion is probably correct, but it should be known at the same time that in-breeding is a perfectly justifiable method of management which may produce very desirable results. The editors of Gleanings in Bee-Culture say:

"Very recently my attention has been called to a series of articles in the Journal Bulletin, the subject of in-breeding to get prize-winning stock. I was surprised to note how the breeders of high-class Jersey blood in Illinois in one or two instances that a mother had been bred to her son, and sisters to brothers, for the express purpose of accentuating certain desirable traits. I observed, further, that this practice has been carried on to great advantage for many years. Breeders have been those who learn from the breeders of other fine stock. But we have one difficulty to contend with, and that is, that a partial strain of a queen mates to a particular strain of drones."

In the same paper J. H. Gerbracht says:

"I think I will say a word right here about in-breeding. There is not in existence to-day a single strain of superiority of either cattle, hogs, or chickens, in which this principle has not been employed to secure a fixed type. The true line of horses, for example, can be maintained only by the most careful and scientific line-breeding. Crosses between different strains produce just the same unreliability and tendency to degeneration as crows of distinct breeds do, except in the few cases where a breed or strain, through the exercise of most unusual good judgment, the two strains happen to 'nich' well. In cattie and swine breeding, the infusion of one-eighth new blood is considered enough to off-set whatever ill effects close in-breeding may produce, the idea being to use the least possible amount to maintain the vigor and stamina with as little disturbance of characteristics as possible, and if cross-breeding a bee breeder depends to a great extent on his ability to do this accurately.

In-breeding, particularly in the varieties which have variegated plumage, in-breeding and line-breeding are the only ways by which any effect of crossing is observed, and some breeders boast of not having gone outside of their own yards for breeding-stock for 30 years. Of course, the results are sometimes the same as those attained by some breeders of five-banded bees—good to look at, but of no utilitarian value; but this is by no means necessarily the case; and the best lay- and most vigorous-growing stock we have to-day is from this same line-breeding."

Assaulting the Bees.

A writer in Bahminton says that in India, about eight miles from the town of Jabalpur, is a place called The Bee, from the fact that swarms of the insects live there and defend their holding against the world. Shocking are the tragedies which have resulted from affection of the skin made by the bees. But every time that they have had their heads above water, the insects settled upon them in clouds, and they chose drowning to a more horrible death. Bees and, even the lordly tiger, have paid the same penalty for their indiscretion. Says the Englishman who describes the affair:

"I determined to invade the home of the bees, and I began by designing a suit of defensive armor. It was a suit of leather, with a cap, tied round the neck with tape, a bee-veil to be tucked into the garment, riding-boots, gauntlets, and two pairs of gloves. Each of these suits was in my opinion, as well as in the opinion of the bees. I was bow served by the tailor, so that there should be no chink or crevice.

"Abraham, a native, I armed and carrying a bucket and two coils of rope, were to climb up to the back of the hills so as to get above the bees, and were to attack them in charge of the boat, ascended the rocks. He went to the bank of the river, which was under the point of attack, and made haste to the place.

"Abraham and I climbed to a well-considered height, and then I left him and crawled cautiously forward. I could hear a sort of alluring hum, dominating the noise of the water beneath, and my nostrils were filled with that sweet smell which is made up of honey and bees.

I decided that the point of attack was about Standard Bred Queens.

Acme of Perfection. Not a Hybrid Among Them.

IMPROVED STRAIN GOLDEN ITALIANS, World-wide reputation. 75 cents each for $4.00. Long-Tongued 3-banded Italians bred from stock whose tongues measured 25-100 inch. These are the red clover bustlers of America. $1.00 each, or 6 for $5.50. Safe arrival guaranteed. W. F. MUTH & CO. Headquartes Breeder of Beekeepers Supplies, S.W. Cor. Front and Walnut Sts. Catalogue on application at 10 cents, 0. Please mention Bee Journal when writing.

ALBINO QUEENS. If you want the most gentlest and prolific Queens—If you want the gentlest bees for your most honey-gatherers you ever saw—try my Albino. Untested Queens in April, $1.00; Tested, $1.50. J. D. GIVENS, LIBERTON, TX.

BEE-KEEPERS' SUPPLIES.

Mention the American Bee Journal.
The Bee-keeper’s Guide; or, Manual of the Apiary,
By
PROF. A. J. COOK.

400 Pages—16th (1899) Edition—18th Thousand—$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific work ever published on the subject. Fully illustrated, and all written in the most fascinating style, it is sure to be a welcome addition to the library of every bee-keeper, and to the library of the whole bee-world to require any introduction. No bee-keeper is in any sense complete if he does not possess a copy of this library complete, without The Bee-keeper’s Guide.

This 18th and latest edition of Prof. Cook’s magnificent book of 400 pages, in neat and substantial binding, is now being issued gratis to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to present subscribers only and is non-premium also is given to new subscribers for the Bee Journal for one year:

Send money to our office to the Bee Journal (with $1.50), and we will mail you a copy of Prof. Cook’s book FREE as a premium. Prof. Cook’s book alone sells for $3.50, or we will fill it with the Bee Journal for a year—both for only $1.75. Begin cultivating your connections for two NEW subscribers to the Bee Journal for a year, and then get the book as a premium. Let every body try for two new subscribers.

GEORGE W. YORK & CO.,
144 & 146 Erie Street,
CHICAGO, ILL.

One Home in Colorado for Sale

I have a fine Fruit-Ranch of 14 acres here at Frutta, all set to fine fruit, principally winter fruits, prunes, plums, prunes, prunes, pears, plums, cherries, prunes, prunes, and about 400 grapes; 100 varieties of peaches, mostly Italian, and about 100 fine Belgian hares that I will sell with the place. The orchard is in fine bearing, being about 10 years old, and is clean and free from weeds. The house is a good 7-room one, nearly new, with bath and water; a good new barn for two horses and one cow, and two barns for two cows; good brick kiln; those two cellars, good lawns and shade. I have a good turn with the place, with an abundant supply of water and an abundant supply of water and an abundant supply of water. I have a good turn with the place, with an abundant supply of water and an abundant supply of water. The price of the place this year will be about $2,000. It joins up to within 20 rods of the town site of Fruita, where we have one of the best schools in the State, and employing 7 teachers. It is only 1/2 mile to the depot, churches, school and post-office, and has telephone connections with all parts of the State. This is a good, healthy climate, and good society.

Address for terms and further particulars.

Catnip Seed Free!

We have a small quantity of Catnip Seed which we wish to offer to our readers. Some consider catnip one of the best foliage plants. We will mail to one of our regular subscribers one ounce of the seed for sending us one New subscriber to the American Bee Journal for one year, $1.00; or we will mail to any one an ounce of the seed and the American Bee Journal one year—both for $1.00; or we will mail an ounce of the seed and one year’s subscription to any one of our agents. Our stock of this seed is very small, better order soon.

Prices subject to market changes.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

- 10 lbs. $1.00
- 25 lbs. $2.50
- 50 lbs. $5.00

Prices subject to market changes.

Also some NEW GOODS that have not yet been advertised. The exhibit will be conspicuously placed in the Gallery of the Agricultural Building.

If you have never seen a Ball-Bearing Cowan Honey-Extractor,

Here is your chance.

We expect that HUBER ROOT, the youngest member of the Root Co., will be the man in charge of the exhibit. He will be pleased to meet all our old friends, and make new ones wherever possible.

**Gleanings in Bee-Culture**

Will contain a very interesting series of articles on Queen-Rearing, giving New Methods and Short Cuts. There will also be a series on **Bees in Law**.

E. R. Root will tell of his trip through Texas, Colorado, Oregon, and California. Better subscribe now.

Six months' trial subscription for only 25 cents.

**THE A. I. ROOT CO.,** Medina, Ohio. (U.S.A.)

GEORGE W. YORK & CO., 144 & 146 Erie Street, CHICAGO, ILL., are headquarters for ROOT'S BEE-KEEPERS' SUPPLIES IN CHICAGO, and would be pleased to send samples or new lists of material on which you may be interested.

Pan-American Exposition

... AT BUFFALO ...

Weekly Budget.

Mr. W. J. Pickard, of Richland Co., Wis., called on us recently, and reported quite discouraging prospects at present in his locality. Their 400 colonies require feeding to tide them over until the blossom flow.

Mr. Huber Root, who so faithfully and successfully managed the stereopticon at the Chicago convention last fall, will have charge of the exhibit of the A. I. Root Co. at the Pan-American Exposition. He is the youngest of the A. I. Root family, we believe.

The W. T. Falconer Co. and the A. I. Root Co. will have exhibits at the Pan-American Exposition, in the Agricultural Building. These exhibits will be conspicuously placed in the gallery, this gallery being reached by means of a traveling stairway. The two exhibits are placed together in the same booth, as were, facing each other—Cleanings in Bee-Culture.

Opposers of Long-Tongue Bees—one of our subscribers writes that it is a "silly statement" that some bees' tongues are longer than others, but it may turn out to be a very important thing for bee-keepers, and then there may be some unpleasant eating of crow. One curious thing is that the bitterest opposition to long tongues comes from the same quarter where the mostfrantic efforts have been made to get bees from India just because they have longer tongues. Long tongues may not be of any consequence, but then they may.

Let us wait and see.

Mr. R. G. Haun is one of our faraway Western subscribers. When sending in the nice picture of his apiary, shown on the previous page, Mr. Haun wrote us as follows:

I am 70 years old, and have always led an active and laborious life. Several years ago I gave up the ranch to my two sons, and that left me nothing to do, which I consider a bad thing, even for old people. In looking around for some sort of employment suited to age and acquired habits of life, bee-keeping seemed to be the thing. First, because I dearly love it, and, second, because it would make money financially.

Several attempts had been made to introduce beekeeping into the Kittitas valley, but each had proven a failure, and I was the first one to succeed in getting them to winter all right, and improve a fair yield of honey. Our honey is of the finest quality when one knows how to secure it. Our first yield in the spring is usually pention from willow, then we have fruit-bloom and dandelion, and our surplus comes from white clover. After that there is not much of a market, and I would like to see on my place one has long-tongued bees that can work on red clover.

I aim to keep from 40 to 50 colonies in 8-frame simplicity hives, and get an average yield per colony of between 40 and 50 pounds, spring coming on as well as it did last year, the bee-business here, namely, excessive swarming, dampness and mould in winter, and a poor market for our honey, our market being flooded with cheap honey from outside. When I first started in the business I produced one third of a pound of honey, and now I am producing extracted honey, which candies almost immediately after being extracted.

I believe that swarming may be partially checked by giving plenty of ventilation. I do this by inserting the bottom of the body and bottom-board, making the space one inch to begin with, and enlarging it as the season advances, to a 3-inch opening in front. Then in real hot weather I give ventilation at the top.

I extract before the combs are all capped over. Honey from fruit blossom and dandelion is a little strong, and somewhat bitter. This honey, when extracted, soon candies, and I let it stand as hard as possible, then setting it on the stove in a vessel of water, heating it pretty thoroughly, then set it away until it again comes; after three days' operation, and set it away in open cans covered with netting to keep out the flies, and it is not long until I have a very fine quality of honey that sells readily, and gives good satisfaction. I peddle my honey in the home market. At first I had trouble in selling it, as nearly everybody was afraid of adulteration. But as soon as people came to know me, and that I produced the honey in my own apiary, the adulteration scare helped me to sell it.

One day I opened a jar of honey for a lady to sample, and found a beeg's leg in it. Several children were standing by, and I, as a joke, said, "You see, this is genuine honey; here is a beeg's leg in it." I made the sale. I went up the street a little further, and when going to home I found a little girl sitting there running into the yard, shrieking. "O mamma, come quick; here is the man with genuine honey with beeg's legs in it!"—R. G. Haun.

The Bee-Keepers' Society of Erfurt, Germany, will hold its 50th anniversary this summer. An interesting exhibition is planned in connection with this convention or celebration. Bee-keeping of a hundred years ago is to be shown. One hundred hives and fifty or more colonies of bees will be on the ground, and will be prepared and started for the heath in Thuringia at the close of the festivities. A portable apiary of 30 colonies (wanderwagon) will also be on exhibition.

Mr. F. Greiner reports this in his cleanings in Bee-Culture. The oldest bee-keepers organization in America is only about 20 years old, and it has had its name changed several times though only "married" once, we believe. The next meeting will be held in Buffalo, Sept. 10, 11, and 12. Are you going to attend?

Mrs. Geo. Jackson, in the Bee-Keepers' Review, speaks thus about boys and girls taking up bee-keeping:

"I, too, believe that bees combine best with bees: therefore, get more bees. If you have children to help, keep more bees. Bring up your boys and girls in the business. Have them work, study and think, the same as they would in preparing for any other profession or trade; for it is distinctly a business of itself, and a paying one, too. Then, why let your boys and girls get away from the good of out-paperies; plenty of profit. I believe there is a better opening in bee-culture to-day for a young man than in almost any other line. It is equally good for girl or boy."

Advanced Eggs—An amusing mistake occurs in the Progressive Bee-keeper. A subscriber asks how soon after a swarm has issued it will be advisable to take away the queen to let the colony rear a queen. The editor replies not to disturb the old queen till four frames are filled with eggs, that in this case, once in the egg-laying position, to know that some think that such advanced eggs as the bees would choose will not make the best queens, etc. Of course, larvae were meant in place of "advanced eggs."
Swarthmore's System of Queen-Rearing, as given on another page, is well worth a trial. The part that costs, as he well says, is the part after the young queen emerges from her cell up to the time she commences laying. If Swarthmore's plan proves a practical success—and it certainly has a pronounced tendency in that direction—that to be force of bees than has heretofore been used during this expensive period, and it is the size of that force that has caused the expense. It is given now in good time for a thorough trial.

A "Large Force" of Bees—What Constitutes It?—Speaking of strong colonies, the editor of Gleanings in Bee-Culture said, "By a 'large force' I mean a colony the bees of which will weigh 8 or 9 pounds, or what would aggregate in numbers 49,000, or 50,000." Dr. Miller replied:

"Are you not a little modest, Mr. Editor, in demanding only 49,000 to 50,000 bees for a 'large force'? L. Stachelhausen says, "I have, in large hives, many times observed that the queen had laid, during the previous 21 days, 2400 eggs daily, on an average." Three weeks later about all the bees from that 21 days' laying ought to be on hand, making 71,400. If we count the life of a worker six weeks, then there ought also to be present bees, say one egg of the preceding week. Say the queen during that time laid 2400 eggs daily, and allow that half that number had been lost by fatalities, we should have 21,000 to add to the 71,400, making 92,400 in all. Perhaps that is not often reached, but I suspect it is nearer the right mark than 49,000.

That answer seems to be carefully built, and yet it is only reasoning that such a number of bees ought to be present, which is a different thing from citing a case in which such a number of bees has been present. Editor Root returns to the charge by citing actual cases. He says that when they bought swarms by weight the average weight was 5 or 6 pounds, and some tremendous swarms that had to be hived in a two-story chamber weighed from 8 to 8½ pounds. As 1½ pounds at 430 to the pound would make 385 bees, he thinks his estimate of 40,000 to 50,000 none too low. He thinks the Doctor wrong in assuming that all eggs laid by the queen are matured as bees, because bees certainly in some cases destroy eggs, and he says: "I think we would be safer in saying that, out of 20,000 to 30,000 eggs laid by a queen, we could not expect over 40,000 or 50,000 bees." The Doctor, in reply, questions whether eggs are destroyed by bees unless queenless, and the editor closes the controversy by challenging the production of a colony of bees that will weigh more than 9 pounds, equivalent to 10,500 bees.

There are two questions of fact in this controversy that it would be interesting to have settled. What is the largest force of bees that may be secured as the progeny of one queen? That ought not to be a very difficult thing to determine by actual weighing. Certainly it ought not to be difficult to determine whether 40,000 or 50,000 is nearer the right mark. The other question may not be so easily determined. Is it true that of all the eggs laid by the same queen, in the same hive, at the same time, in the same year, 80% are drones? If it is true, it would seem a very wasteful thing. But if a queen lays 3000 eggs daily for six weeks, and her colony weighs only 9 pounds, it is hard to get away from the conclusion that nearly half the eggs have been wasted.

Moving Bees Together for Winter.—In the Bee-Keeper's Review is given a picture of an apiary of E. B. Tyrell, the space between the hives in a row being just enough to allow another hive to be placed between, the object being to move the two rows together into one solid row for winter. Before packing the bees for winter the two rows are now moved together, a little at a time, one row being moved backward, the other forward. Of course, this takes only about half the labor, and very much less than half the packing material it would take if the two rows were allowed to go through winter as in summer.

Here is another way that gets them into still more compact form:

<p>| | | | | | | |</p>

Here are 36 hives in four rows, and, of course, the rows could be continued to any length. The first row of 10 hives and the second row of 8 hives both face the same way—toward the top of the page. The third row of 8 hives and the fourth row of 10 hives both face the bottom of the page. That makes the central two rows stand back to back. When winter approaches, the first row is gradually moved back until in a straight line with the second row, and the fourth row is moved back in line with the third row, the four rows now standing in two rows thus:

Food of Queens, Drones, and Larvae.—Among American bee-keepers there is a feverish anxiety for immediate results, and they pride themselves on being intensely practical, but they would have better success in the long run if they would take the trouble to inform themselves upon some of the elementary matters that have been carefully worked out by scientific men, especially in Germany. In the Progressive Bee-Keeper, L. Stachelhausen gives a succinct manner some things about the prepared food which although by no means new, are probably new to the majority of bee-keepers. Asked whether at the time of contemplated swarming the workers withhold from the queen the egg-protein food, he leads us up to an affirmative answer by giving the following information:

The queens and drones never eat pollen, but are fed chyle by the workers, which is fully digested pollen, and is identical with the blood of the bees. They may also help themselves to honey, which is fully digested nectar. So the queen does no digesting, but is entirely dependent upon the workers. This freedom from the burden of digestion, and being fed so freely with food that is concentrated and nourishing, explains how it is that a queen, whose body without eggs weighs only 0.30 grains, can lay in 24 hours 3000 eggs weighing 0.01 grains, or three times the weight of her body.

"The larva receive quite the same food, that is, chyle regurgitated from the stomach of the worker-bee. Nevertheless, we find the necessary difference in nourishing of the different kinds of larvae. Queen-larve are supplied with pure chyle till the cell is capped in large quantities: we call this food "royal jelly." Worker and drone larvae receive the same chyle during the first three days only, afterwards the food is less digested by and by, and we call this food chyme. From the fifth day, till the cell is capped, honey and pollen is fed to worker as well as drone larvae."

Michigan Bee-Keepeers will serve their own interests if they will read the following, and follow the suggestion made:

To THE BEE-KEEPERS OF MICHIGAN:

I take this method of informing the beekeepers concerning a few points in regard to the Michigan fruit-brood law. A locality must be reported to the Dairy and Food Commissioner, Lansing, Mich., before it can be inspected, and as our funds are limited it would be a great saving if the beekeepers would work with the Inspector by reporting all localities where fruit-brood exists, or where it is thought to exist, as soon as possible. If this is done it will enable the inspector to plan a trip through the State and cover the whole territory to be inspected at a much smaller traveling expense. Localities first reported will receive first attention, and those who neglect to report their localities until late will in all probabilities be obliged to wait until next year for assistance.

John M. Rankin, Inspector.
Early or Late Requeen of Colonies.

By C. P. DADANT

Mr. C. P. DADANT: In the American Bee Journal of Feb. 11, I had an article, one paragraph of which related to the introduction of queens for early requeen. I said that by requeening one month earlier in the season, the queen-laying was cut nearly in half, and that the queens were ready for fertilization the drones must have been too scarce, although we had taken pains to keep all the bees in a feeding condition, for many of the young queens was fertilized, and the following spring we had ten drone-layers of the very best quality in ten of our very best colonies. And, by the way, let me here remark that the honey bees are a very good source for early requeening. We took advantage of this to rear early queens, and they were all purebred before the impure drones hatched in our neighborhood. The possibility of the queens falling to make such use of this, or any other argument against requeening an apiary late in the fall.

There is perhaps another objection arising from the difficulty of manipulating hive much in cool weather, and when robber-bees are as alert as they generally are at that season. But these objections fail to embarrass a practical apiarist. The only objection, if there is one, is the risk of losing colonies through precautions to avoid disturbances. In out-apiaries, however, where a man can give his personal supervision only at times, I should not like to do much of this handling after the honey crop has ended.

I would suggest that the most economical plan to requeen would be to rear queens more or less during the entire season, and requeen as we go. If, however, we change the bees we do, after a period, it would hardly do, for the brood was hatch, unless the season was particularly favorable, and we could make sure of securing a sufficient number of drones as late as desired. Since Mr. Bevis has succeeded, it shows that such thing can be done, and if the advantage of not disturbing bees is taken during the crop. If the queen is removed before the end of the harvest the brood that hatches out will give room for honey in the brood-chamber, and quite a portion of the crop may be taken out of the house, or the rear of the chamber, if he resorts to the extractor.

Hancock Co., Ill.

Scientific Names—Melillera Not Mellifica.

By Prof. A. J. Cook

We have all become used to the name, Apis mellifica, to designate the honey-bee. Some will wonder why we change to "Apis mellifica." The specific name in both cases comes from the root for honey, and either would seem appropriate. Why, then, give up a name which has been so long in use, for one no more apposite, and which is an entire stranger to us?

Our present method of naming animals and plants was originated by the great Swee, Linneus. It is called the binomial nomenclature. Every species has a name of two words. Some of the species names have been used in designating plant or animal. Thus we have the generic name and the specific name. In the honey-bee the generic name is Apis. This is broader in its significance than the specific name, and versata, the honey-bee of India, as well as the ordinary honey-bee, of which, as we well know, there are many races.

The specific name, on the other hand, refers to only one kind of bee. All the individuals of a species will be very nearly alike. Where any species is placed under varied conditions the individuals will tend to vary, and thus we have what are known as races. In our domestic animals, where man places them under such very different conditions, they will vary more than they would in nature, and so races are very common among our domesticated animals.

I think the races of our bees—Italians, German, or black, etc.—were generally formed by nature alone. The races we have will have habits and general peculiarities that are much more similar than will the different species. I think, too, they will be more apt to vary in their own characteristics. Our dogs and horses are good illustrations of the same kind. Our dog may not have the same breed as its own stock, but they are all dogs one species—Canis familiaris. Yet how different are the poodle and the Saint Bernard, and how numerous and how varied are all the intermediate breeds. Our horses, too, are so diverse, and it is hard to say how different the individuals of the horse species. The Shetland pony and the Normall wear illustrate a different environment with careful selection may do in modifying a species. The old idea that animals of the same kind may be treated as one species would be true were found to be untrue. The mule—a cross between the donkey and the horse—two obvious species—made it necessary to change their classification.
to modify the old notion. But as we all know, the nule is infertile. It was then stated that only animals that would interbreed and the offspring prove fertile belong to the same species. I think this is pretty generally true among the lower plants and animals. But I think there are numerous exceptions among the lower plants and animals. I think there are cases on record where different genera interbreed, and the offspring are fertile. Of course, such cases are very rare.

As we understand from the above, the nature of a genus and a species, which may be better understood by comparing them to our own names, the genus standing for our surname, and the species for the given name, we are unprepared to discuss the change of name in the honey-bee. This change of names, not only of insects but of all plants and animals, is very common. I know of some insects where the names have been changed two, three, and even four times during the last few years. It comes about in this way:

Two or more persons describe the same insect or other animal. Of course only one of these names can be selected. It has been decided that only the first name should be adopted. It is unfortunately true that sometimes the first name and description appeared in some obscure publication and were for a long time unknown. Therefore the second, third, or even fourth name was for a long time used in speaking of the insect. After a time, it may be for years, someone discovers the name and description, given third in order, we will say. Of course the old name gives place to this. Afterwards the second one may replace this, and finally the first and rightful name is unearthed and manifestly this takes precedence of all others. It is obvious that this frequent changing of names is a great hindrance to science, and a tremendous annoyance to the student; yet it is certainly the lesser of two evils.

It is now stoutly urged that every first description of an animal, where, of course, the name will be given, be published only in some standard scientific paper that every student of the science may have ready access to it, and may know of its existence. It is also equally important that every person in naming an insect and describing it take all possible diligence to make sure that the same species has not been previously described.

The father of this system of naming, who may almost be said to be the father of botany and zoology—Linnaeus—gave the first to describe our honey-bee, he described it as Apis mellifera, and so, of course, this name has priority and must be accepted.三年后 later, he described the same insect again under the name Apis mellifica, the name which has been used ever since. It is strange that the same person should describe the same insect twice under the same name, yet when we remember the amount of work Linnaeus did, and the astounding number of descriptions he made, it is not strange that he should have forgotten that he had previously described it. He should have named and described the same animal or insect a second time.

It is to be hoped that all our bee-papers as well as writers, will make a point of bringing this new name prominently forward, that very soon it may seem as right and natural as the old one. We are certainly fortunate in the name, which means honey-bearing. This name, then, will suit those nervous people who proclaim in the face of the truth that the bee simply gathers honey and does not produce it. Neither is the truth malign in this new name, for although honey is certainly a digested product, and so produced by the bee, we can still say that the honey is a honey-bearing.

So hereafter we will all unite in the name Apis mellifera for our pets of the hive.

Los Angeles Co., Calif.

The Swarthmore System of Queen-Rearing.

BY "SWARTHMORE."

A GREAT deal has been written, said, and done to simplify and cheapen methods for cell-getting, until now queen breeders have about all that can be desired in an almost perfect system of cell-work, from the egg to the mature queen, her care after hatching, and all that. But cell-getting is not the expensive part of queen-rearing; in fact, it does not represent an eighth part of the work connected with the securing of a laying queen, ready for posting to the customer far or near.

The great expense in queen-rearing is that necessary for the proper fertilization of the young queens after they are reared. The queen-breeder, heretofore, has been obliged to tear asunder large numbers of full colonies to form nuclei of a frame or two each to receive the young queens. Each in a separate colony for mating purposes only.

Now, all this is expensive—not alone in bees but in time, labor, care, and a hundred other ways. Full colonies are ruined, and all revenue from bees thus treated is entirely cut off until a laying queen is secured, sold, caged and mailed. All this woful waste has set me to thinking about a plan of operation to lessen the expense and labor in queen-rearing at the mating period.

Some years ago I succeeded in mating a number of queens from 4¼ x 5¼ section-boxes, each supplied with a teacupful of bees; but not until that past season have I been able to say that I have discovered a practical method of mating young queens by the section-box plan, although I have used them now for about 13 years.

The plan I have adopted is as follows: Hive a good-sized swarm (natural or forced) into a body containing ten all-wood or Simplicity frames, each frame filled with 4½ x 5½ x 1 inch one-piece plain sections, thus:

![Frame with Foundation]

Each section should be supplied with a starter of brood foundation, as shown, and the frames are set rather close together until fully drawn out by the bees. Unless honey is coming in rapidly the bees should be fed constantly during comb-construction, in the event of the swarm being a forced one.

In a few days a good, prolific queen will have filled the most of these little combs with eggs, and in due time it will be found that each little comb has its supply of brood, honey, and bee-bread—the exact condition necessary for the successful formation of nuclei for queen-fertilization. At this point take away all the section-holding frames, supplementing them with full sheets of capped brood, honey, etc., taken from other colonies; put on the surplus arrangement, and close the hive. This colony will yet show you honey before the end of the season; even though you have borrowed every particle of their work from the time of hiving. Let them work on; you will not need to molest them more.

Remove the section-holding frames now clear of bees, just as taken from the hive, to the honey-house, and adjust

---

**FRAME WITH FOUNDATION.**

---

**TOP OF FERTILIZER NUCLEUS-BOX.**

A, lid; B, section box frame; C C C, hive-staples, for guidance; D, perforated zinc; F, cork in flight-hole.
To each side of each little comb, containing brood, a cover made of the stuff, with 1½-inch strips nailed all around the edges; as shown at A, Fig. 1. Four small staples, C C C C, driven part way into each corner of the lid, so as to project or telescope into the section-box, will serve to hold the lids in place until they have become glazed a bit by the bees.

When the lids are all in place, each little comb will be in a compartment by itself, and each compartment may be entered by the bees through the perforated zinc that covers the two 1½-inch auger holes in the center of each lid, as shown in the drawing, E E, Fig. 4. The zincs are nailed fast to the inside of each lid. Pieces of section stuff do very well to close the zinc-covered holes when occasion demands (see dotted lines in Fig. 4). A 1½-inch flight-hole is cut just below the two large holes in one lid only. This is stopped with an ordinary druggist's cork, which is easily drawn when queens are to be introduced.

Now run a perfect-winged and sound-legged young virgin queen into each compartment; then recork the flight-holes and expose the zincs on all sides so that the bees can readily enter all the compartments from the sides, yet no queen can leave the compartment in which it is intended to restrict her. Then hang the frames in the hives of such bees as you may have just used in getting a batch of cells, or any queenless and broodless bees you may have at hand. Be careful, however, that there is no sort of queen with them, virgin or otherwise; and if they have been over three days queenless, a little tobacco smoke should be used.

A very simple way of supplying the compartments with young queens is to attach a ripe queen-cell to each comb before adjusting the lids; then hang the frames among queenless and broodless bees with flight holes corked, and zincs exposed. The bees will at once occupy the compartments, and in due time a young queen will hatch inside each compartment.

Any queenless bees will soon enter the compartments, and care for the brood and queens; and as soon as they become settled, feeding may begin. Feed a little sugar syrup (no honey) each day; and at the end of the fifth, if the weather is fine, remove the frames carefully, bees and all. Close all the entrances so none can escape from the compartments. If the weather is very warm, cover the holes on the flight side with wire net, as shown in the

![Fig. 4](image)

**Fig. 4.** Bottom of Fertilizer Nucleus-Box.

Fig. 4 is a view of the under side of H, showing holes uncovered; B, part of section-box; E E, holes covered inside with perforated zinc; F, all holes covered; dotted lines show position of thin board when excluder-holes are covered.

Fig. 5 shows the construction of a confinement-screen. A 3-foot piece of 1½-inch ply wood, 1 inch thick, is fastened to an 18-inch piece of 1 inch sheet zinc by six wire-nails. A 2-inch piece of 1 inch sheet zinc is nailed to each side. These sides are covered on top and bottom with a 1½ inch sheet zinc.

![Fig. 3](image)

**Fig. 3.**

SWARTHMORE'S FERTILIZING-FRAMES, WITH NUCLEUS-BOXES IN PLACE.

Toward evening open the flight-hole to each compartment—three on one side and three on the other, as shown above by the letters F F F. If the next day or two be fine, each and every queen will leave its little chamber to mate, and just as large a percentage will return safely as by any method of nucleus management now in vogue. The life of these little colonies may be sustained several weeks by feeding lozenges of "Good" food every three to five days. Press the food into the holes at the back of each box. The blocks of Benton mailing-cages may be filled with "Good" food attached to the back of each compartment by two staples driven into the ends of same and hung on two cor-

![Fig. 5](image)

**Fig. 5.**

During the next few days, the bees may be supplied with water, both in the upper and lower sections, as necessary.

When the bees have been more than three days queenless, the combs may be filled with "Good" food as shown in the engraving, taking in as you do so, as many bees, that may be on the outside of the boxes, as possible.

Take these frames some distance from the old stand, and set them out separately on stakes driven into the ground, thus:

**Bees and Fertilization of Blossoms—Other Comments.**

BY ALLEN LATIHAM.

On page 262, is an important as well as interesting article on the subject of bees and the fertilization of fruit-blossoms, by Thaddens Smith. This article is bound to raise a controversy if not hot words. I hasten to put in my word in support of the writer in hopes to stem the wrath to come from the other side.

Provincetown, Mass., is the town at the extreme end of Cape Cod Peninsula. The land here is from one to two and one-half miles wide. It is swept by sea-breezes almost all the time. It is thus a poor place to keep bees. No bees at all are kept, as far as I can find. I have my summer cottage there, and in the two summers that I have spent there I
have not seen a single honey-bee. Right in front of my cottage is a fertile meadow in which the white clover stands nearly knee-high. Many bumble-bees may be seen on this, but not a honey-bee more.

This was the way that I had found out that I have to do with the matter which I began with. Just this—that region is extremely fruitful. Never have I seen small fruits in such abundance as there. Bushels of wild strawberries are gathered in June, July, August, and September, and they had been dragged on the bushes to the ground. There are blueberries, huckleberries, blackberries, raspberries, wild cherries, and last but not least, beach-plums. The shad-bush berries, or June-berry, have a musky smell which they have when ripe, as they are called in Provincetown, "juicy pears," are the most wonderful fruit (unless I except beach-plums) I have ever seen. I left the cottage one day to get some for pies. I was gone less than an hour. I rode on my bicycle, then walked the rest of a mile, then picked two five-pound honey-pails full, then walked and rode back. You can see from this how thick the berries are. I have seen the smaller bushes lying flat on the sand, drawn entirely out of the fruit. One could easily gather a bushel in an hour.

But, oh, the beach-plums! The sand-hills are covered with the scrappy plum-bushes; and the bushes are loaded with the succulent plums. I have often spent an evening gathering these plums by the bushel. The plums are about the size of cultivated cherries. I have seen a cluster of these plums that would yield a pint or more at two scoops of the fingers. One small bush the size of an ordinary currant bush will often yield four or five quarts.

Now how do these fruits form if there are no bees there? I shall not attempt to answer that question. I merely state the facts as they are, and ask how it is done.

**KEEPING QUEENS OVER THE WINTER.**

The question, "How can I winter my surplus queens?" is often asked. Though I can offer no easy way of wintering a large number, I can tell how one or two choice queens can be saved. It is not infrequently happens that a bee-keeper has an extra queen or two which he would like to winter. More than that, he can often profitably use such queens in the spring. Many a time have I had a fine, strong colony in spring queenless. Unless a queen can be given, that colony is not of much value. With a queen it will be ready for the June and July harvests.

Last fall I had two surplus queens of excellence. I could not think of killing them, but I had no colony without an equally good queen. I still had those queens in good health. I took from two strong colonies two frames each of brood with adhering bees. I placed these in a hive prepared as follows: A tight partition was put in the middle of the hive, and strips of newspapers were used as partition. In each side I placed a cushion of this thickness so as to allow two frames between it and the partition. The four frames spoken of above were disposed of in this way. Then I gave a queen from each colony back to the parent hives, only a pint or less remaining in each side.

The care of the hive was then the question. All through October and November (the nuclei were made in September) I either placed a heavy carpet over the hive on cold nights or carried it into the kitchen. The hive had been set close by the back door. On cold days the carpet was left on the hive. When settled cold weather came the hive was covered with a large blanket and placed near the hot water heater with the entrance away from the light. Here it had a temperature of about 50 degrees. When a warm spell came the hive was put out so that the bees could fly. Though they had been well treated they had not touched. The bees did not restless. They came through with small loss in numbers and are breeding up slowly. It so happens that none of my queens died last winter. I shall try to build the little colonies up. They were put out in March, before the snow bore on cold spells. The entrances are provided with screens.

You say, of course, that this is too much bother. There is work in it, but it is that pleasant putting work that I have. A bee-keeper of my acquaintance, who has the lives of valuable queens, which in turn may save the existence of valuable colonies.

**LONGEVITY IN BEES.**

I am glad to see a word from Mr. Doolittle in regard to long-lived bees. Prolificness at the expense of strength has been too long the vogue. We have all had a colony occasionally that had its frames packed with brood. We have fondly looked for great results. They did not come. The colony failed to gain in members though the frames were kept full of brood. All the honey gathered went into the brood. As a rule, they had been brought in by the bees on the other hand, we have seen a colony with only five or six frames of brood. We have turned from it in disgust. Behold that colony a month later. Still only five or six frames of brood. But where did all those bees come from? They crowd the hive and the queen stores two cases. These are long-lived and the right-kind of bees. Let us rear that kind. I do not mind if they have ten frames of brood, but let the bees be long-lived.

Yes, it is a favorable season for long-lived bees, but will offer a few more words. It is easy to see why these bees are of so much more value than short-lived bees. First of all they winter well, coming out strong in the spring, and do not seem so variable. A colony with this length of winter has been more than the kind. Why? In the working season let the short-lived bee live six weeks, the long-lived one nine. Each costs the same to rear. One works from two to three weeks, the other from five to six. The short-lived bees I estimate to be a worker for an average of one week, for the long-lived bee a worker for four weeks. Do we not find the secret of a honey crop right here?

I have a colony that has bees which winter and then give noble aid in filling the first sections. I honor those bees. They are my pets.

---

**No. 6.—Practical Lessons for Beginners in Bee-Culture.**

BY J. D. GERING.

(Continued from page 343)

NOW, see here!" began Mr. Bond. "I am not the least bit sure that I can remember all the things you have been telling me to-day; but I am here to learn all I can. You shut me off twice when I asked questions or put me off, rather. I am going to ask some more questions, and I think you ought to answer them right on the spot.

"First, then, you've told me all about putting supers on this hive until you had five of them on, all in a pile. I'd like to know what you do that for. I can see no sort of sense in it. To me it seems like boy's-play to lift off and then lift back again a whole stack of supers weighing 25 pounds each. Now, tell me, if you please, what do you do such a cranky-looking thing for?"

"I am glad to have an opportunity to enlighten you on that subject, Mr. Bond," I replied. "But first I will inform you that the cranky-looking performance isn't boy's-play at all, in any sense of the phrase—surely not the lifting part of it; that you can readily see for yourself.

"You will not object to my using an illustration that must be familiar to you, in order to impress my answer to your question upon you. I will give you the scene that will stick. Well, you know that hens will always choose a nest to lay their eggs in which has at least one nest-egg in it—the more the merrier, in fact. They will generally avoid an empty, or an unused nest; and hence the fact has been generally accepted by poultry-men, and poultry-women, especially— that it pays to furnish the nests with natural or artificial nest-eggs. The women, at least, think that it encourages the hens to lay. I must confess, however, that I have never known a hen to lay more than one egg a day on that account. And I presume you can say the same, Mr. Bond."

"That I can," he replied. "But, for all that, I don't quite see the point where the illustration applies. Some illustrations don't illustrate, you know. I've heard lots of that kind preached. But, of course, bee-keepers aren't preachers."

"Well, perhaps there is no point for you to see, and my effort is lost," I replied. "I shall therefore give you my answer, sugar-slick."

"The fact is no invention or discovery of my own, that bees will work better and carry in honey faster when they have lots of it stored in the hive. Bearing this fact in mind, it has been the rule with the bee-keepers to 'tie-up' the supers on their hives as fast as the bees fill them, and to take none of them off before the honey-flow is played out."

Those who have been doing this, year after year, have become satisfied that it pays to do it; and that it pays not to do otherwise.

"Of course, I am aware that there are bee-men who stoutly maintain that there is no difference; that they have
always been in the habit of taking the honey off the hives as soon as the bees ripen the honey in the supers, and that the bees always begin to work on the supers. I put, on in place of the one that was removed. But, you see, such testimony doesn't weigh a feather, because it is time-stamped; for, if these bee-men have never thoroughly tried both ways, they have no right to say that there is no difference.

"Now, Mr. Bond, I am fond of testing things, for the mere sake of the thing, sometimes. Hence, when I read about the supers, and the supers, and the supers, and the supers, I never end the honey-rush because of several reasons given, I once tried it. But, in order to test the trial, I made a few experimental observations bearing on the questions. One of the cases was where a colony had gone on out on a strike, as it were. They, for reasons known to themselves, refused to work. All the other colonies in my apiary were rushing the honey into the supers at a furious rate, and had filled from one to three supers each, while this colony had not even drawn on the foundation in the sections of the super on their hive. I had tried everything I could think of to induce them to "get a move on" themselves, but without the result sought. It was a strange case, for the hive was full of bees—ever the super was full during the day-time—and the eight frames were solid with brood and sealed honey.

"Well, sir, I don't now remember how the idea came to me—whether it was dreamed, or heard it related at a bee-keepers' convention—but, at any rate, I did this:

I opened that hive one beautiful morning and took their supers from them. Then I took out two frames that had more brood than the rest in them, and put them to another colony, from which I took, instead, two frames nearly filled with honey, some of it unsealed, and put them into the hive of lazy bees. Next, I took out the frames that had the most honey in them, and with a honey-knife shaved off the capping, thus unsealing a large patch on each frame. This drastic proceeding set a lot of honey loose, of course; but it also broke up the strike. I watched them nearly the whole of that day, and will tell you, Mr. Bond, I had to laugh out loud myself for several times to see those bees hustle themselves to keep that loose honey from going to waste. Of course I was on the look-out all the while to prevent any of the honey from running out of the bee-entrance and tempting other bees to come and investigate matters.

"The next morning those bees went to work in the super, which I had replaced the evening before; and they didn't let up until the end of the honey-fall, when they had filled two supers, and a third partly.

"Another experiment I made—no, I beg your pardon, it wasn't an experiment, but an experience—and it happened thus:

"Before I adopted the tiering-up system I always put on only one super at a time, and then looked through the glass in the side to see when the bees were sealing the outside frame. I saw them do what I took that super off and gave them an empty one. Well, I had observed this before, when I had performed this operation, that there was a very marked slackening-up of work in those hives from what they had taken full supers; but I did not stop to study about the cause. It was not until that same season when I learned how to break up a strike in a colony that I took particular notice of this streak of loafing, or sulking—I am not sure which it was. As I was always working off full supers one morning I found that one of the colonies had put in spare time in building brace-combs between some of the frames, and had extended that kind of work to the top of the frames, for it is the hard filler of the space between the brood-frames and the bottom of the supers that is most important in honey. Well, in taking the super off, this extra arrangement was of course broken up, and on a lot of honey let loose.

"There were several important things about bee-keeping which I hadn't then learned yet, hence I was not aware of the fact that those bees did that extra job because they were short of honey-storing room for several days before I thought it was going to come. Furthermore, I am sure that the extra comb had to be removed before a fresh super was placed on top the frames, I took the honey-knife and bee-smoker and went at it. It was a sweet job of work, now I tell you! But I got through with it without getting more than a dozen stings on my hands; and then put on the super, and cheerfully closed the hive.

While doing that little job of work, Mr. Bond, I learned something that was new to me. When I first began slashing into the comb with my honey-knife I got quite a number of hot stings on my naked hands. As I proceeded, my hands became daubed with honey, and I noticed that the bees did not attempt to sting where there was honey. Taking the hint, I daubed honey all over my hands, with the result that I got no more stings doing that job.

"This recipe I throw in extra, without cost. You can tell by trying it—should occasion call for self-defense some time when you find it necessary to do such work—whether it was my fore- or my back comb. There are occasional on occasions, you know, when a bee-keeper can't keep his hands in his pockets and yet do the work that calls for their use."

(To be continued.)

Questions and Answers

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Millen direct, when they will be answered by the Doctor to send answers by mail.—Editor.]

Building Up Colonies.

My bees wintered well—47 colonies out of 49. A few of them are very strong. What is the best way to build them up? Give them a frame of brood from a strong colony, or exchange hives in the middle of the day when the bees are flying the strongest?

ONTARIO.

ANSWER.—Take from a colony that has five brood or more, leaving it only four frames of brood. Do not give these frames of brood to the weakest colonies at first, but give a frame to each colony that has only three frames, until these are all supplied, then give to the weaker ones. Take the adhering bees with the frame of brood, but be sure you don't take the queen. If you give a frame to any colony, let them be from different hives, for if you should give two frames with adhering bees from the same hive it would endanger the queen.

Filling Combs With Syrup for Feeding—Fastening Queen-Cups.

1. I am the newest and "greenest" of bee-keepers. On page 310, Allen Latham writes of filling brood-combs with sugar syrup from a coffee-pot at the beginning of the apple-bloom. How does he hold the comb during the operation? Height, as it is in the hive, or does he turn it from side to side?

ONTARIO.

ANSWER.—Take from a colony that has five brood or more, leaving it only four frames of brood. Do not give these frames of brood to the weakest colonies at first, but give a frame to each colony that has only three frames, until these are all supplied, then give to the weaker ones. Take the adhering bees with the frame of brood, but be sure you don't take the queen. If you give a frame to any colony, let them be from different hives, for if you should give two frames with adhering bees from the same hive it would endanger the queen.

2. In making queen-cups a la Doollittle, I suppose the bottom, i.e., the thickest part of the cup, is fastened to the stick, is it not?

ONTARIO.

ANSWER.—1. You are no greener than the rest of us have been, but are perhaps a little smarter in finding out sooner your greenness. You may ask questions that may betray your ignorance. When you do not find instruction in your textbook upon any given point, you may gain that instruction through experience, but sometimes that is expensive, and by asking questions you not only gain the desired information for yourself, but help others as well.

Mr. Latham gives no particulars, but you may be sure he does not have the comb hanging, as in the hive, when he makes the comb. Lay it on its side, or turn it up from a height of three or four feet, and the fall from such a height will make the syrup force its way into the cells. It will work better if the syrup is hot, but you must look out not to melt the comb. When one side is filled, turn the comb and fill the other side. Then when the comb in a hive-body that stands over something to catch the drip.

Years ago I fed many gallons of syrup in combs, and to make the work easier I had hung three or four feet above the tub a large baking-powder can, or something of the kind, the bottom of the can being punched full of nail-holes, the holes being punched through from the inside.
With a pitcher in one hand I poured the hot syrup into the can, while the other hand kept the can moving about over all parts of the comb. Having the can thus suspended by strings made it much easier.

2. Yes, my dear, we will do so.

3. Generally there is no trouble in getting bees to take syrup whenever they can reach it. Perhaps it was too cold weather for them to leave the cluster. Sometimes they will take hot syrup when they will not take the cold, the nearer the cluster the sooner they will be to take it. If you put them in combs they will be sure to take it. For fear of starting robbing, don’t give the combs till nearly dark.

**Material for Cell-Cups—What to Feed to Work Them Up.**

1. In making cell-cups for queen-rearing, what is the wax mixed with?
   - In the dry season when the bees will not work up the cups, what is best to feed them so as to induce them to work them up?

**Dividing for Increase.**

1. I don’t care to let my bees swarm. Would it be safe to take one, two, or even three frames of brood from each hive, and when I get 10 frames put them in a hive, making sure that I have not taken a queen from any of the hives? Does it make any difference if there are any bees on the brood-frames? Do you think the bees would fight with each other, because there will be bees from different hives, such as Italians, blacks, and Hybrids, or would you brush the bees off when you take out the brood-frames?
2. What would I do for queens for each new colony thus made?

**Convention Proceedings.**

(Continued from page 357.)

BY DR. L. D. LEONARD.

SECOND DAY—FORENOON SESSION.

The first thing on the program was Pres, West’s address, read by Mrs. Aeklin, as follows:

**President’s Annual Address.**

The Minnesota Bee-Keepers’ Association was organized at Minneapolis about eight years ago by a few determined and loyal bee-keepers, under the laws of Minnesota. Wm. Urie, Wm. Danforth, and B. Taylor, successful bee-keepers who have since passed to their eternal homes, were present at that meeting. There had been previous attempts, made without success, and meetings had been held; the Association got into debt, and was in bad repute. Under the present management the debts have been paid, and there is a surplus in the treasury.

Company with a strong and vigorous society having increased its membership which includes some of the most noted apiarists in the West. When thoroughly organized the society at once took steps to put the honey department at the State Fair—which had become a disgrace to the bee-keepers of the State, under the supervision of honest bee-keepers. From that time until the present that department has gradually grown in size, quality and importance, in fact, no department of the State Fair has shown such marked improvement with the same amount of money expended.

Through the influence of this society a grand exhibit of the products of the little “busy bee” was made at Omaha, which demonstrated that the finest honey—as well as butter—comes from the grand, young State of Minnesota. The exhibit was a grand surprise to every one, and won great honors for Minnesota. Exhibits were made by some of our bee-keepers which won 100 points.

Through the influence of this society a law was passed by the State legislature, making it a crime to sell or offer for sale adulterated honey, unless the package containing the same be so labeled, and it is provided that any person violating this law may be prosecuted and punished. This law was passed by the State Board of Agriculture, and is a very good provision.

The rapid strides made in the art of apiculture during the past 50 years is in keeping with the rapid strides made in all other departments of life where genius and invention have been developed, due to the energy, enterprise, and self-sacrificing labors of such men as Father Langstroth, Moses Quinby, Adamum, John H. Adams, A. E. Mainum, Prof. A. J. Cook, Dr. A. J. Boardman, Dr. A. B. Mason, Chas. D. D. Anderson, Bar., D. A. Jones, W. Z. Hutchinson, Dr. C. C. Miller, A. J. Root, E. K. Root, and a host of others, whose bright and inventive minds and consistent lives have made, or are making, the bee-papers of to-day superior to the papers printed in the interest of any other line of business. What other branch of learning or occupation has had such honest, heroic, self-sacrificing, devoted and eminent workers? Their influence and superior qualities of heart and mind have blessed all other departments of life in...
which they move. And what a pleasure it is on such an occasion as this to speak kindly of them, and to accord them a high place in our history.

Instead of the old straw hive and the log gum the inventions of the early American apiculturists have given us the frame so admirably adapted for the home of the worker bees. And every kind of manipulation and theory are developed, and from which all other hives in a measure have been evolved. The large, unwieldy and unmarketable honey-boxes have given way to the frame of one-piece construction—a convenience and blessing to the apiculturist, and which in its simplicity and cheapness is within the reach of all. From the swinging of the dinner-pail in which there was a piece of comb honey, around and over his head, the young, sick, and uneasy boy—which operation his father noticed threw the honey outward of the comb—came the honey-extractor now so generally used, a great help to every well-cared for apary, and even the present day honey knife and comb knife, for which there is no universal appreciation by the successful apiculturist.

Then comes the little queen-cage with candy, a great improvement and source of profit—a means by which the queen—indeed and in truth the most wonderful and interesting of all insects known—is transported from all parts of the globe, and we have thus been able to improve our race of bees, to be used in our hives, the Dowlittle method of rearing queens; the honey-board, the wax-extractor, the queen controller, wired frames, the foundation-faster machine, bee-feeders, bee button, separators, and the improved method of procuring comb honey; and very many other improvements and devices help to make the labor easy, successful and more profitable, and are valuable for the interest of the therapeutic apiculturists in some department of their art.

The tendency of our occupation, then, like all other things, is toward greater efficiency. This is a race of intense activity and progress—the tide is fast bearing us onward and upward. Some are wishing for the good old days gone long ago, but these are the best days since the stars first sang together; when the Messiah was found in the manger, and 1, for one, am glad I am living now. Bee-keeping is wonderfully interesting and fascinating to the successful apiculturist. It brings us in contact with one of the most wonderful little creatures in God's glorious universe. The man who has bee-keeping, has a world of mental and physical enjoyment around him: the seasons, the fields, the hills and valleys, and all the creatures on the earth are clothed in glory; but nowhere, nor in any other creature, is the wonderful and admirable adaptation of the queen, to the worker, in the "one-bee." The manner and thoroughly practical governmental in the home, the power and adaptability of the queen with her bodyguard, in that home for its good and success: the tiny eggs which she never tires of depositing by the thousands until old age shall claim her; the care and attention of these eggs by the nurses of the family; the food and growth of the young bee from the time it begins to show life until its birth into that home; its care after birth; the different kinds of deposits, and food which produces from the same mother the workers (either male or female), the drones (the male bees), and the queen, which produces respectively the worker in 21 days, the drone in 24 days, and the queen, much larger than the worker, in 16 days; the wonderful means the worker has of constriction of the cell for strength and economy; the ability of the workers to gather nectar from the blossoms and flowers of the fields and trees, which, when stored in the home becomes one of the best foods and medicines, for food and health.

Honey has great healing and soothing properties, and is an excellent medicine for sore throats, lungs, cuts or sores of any kind. Dr. McDonald, of this State, informed me several years ago that he used the poison successfully for rheumatism and dropsy. Honey as food is very strengthening and healing to the system. It is said that during the Russian and Turkish war, in crossing the mountains the soldiers were weak and cold from lack of food. The Russian general ordered that the soldiers be fed with honey every day—a ration which at once revived their spirits, and strengthened and warmed their bodies. In ancient times it was regarded as almost sacred, being the best food, medicine and drink, when prepared, to be found upon the earth. In Abyssinia, Russia, India, Palestine and other countries, refreshing drinks are made from it. In ancient Egypt it was valued as an embalming material, and in Rome for the preservation of fruits and the making of cakes. In India a mixture of honey and milk is a respectful offering to a guest, or to a bridegroom upon his arrival at the door of the home of his bride's father. To the ancient Eumenides, a mixture of honey and milk was also an offering to the gods. Wherever kept, as their value in fertilizing blossoms of fruit and clover can not be estimated. Our occupation brings us in contact with one of God's best gifts to man, and opens up a field for labor, as flattering as any other where the results of the capital is invested. Yes, more than this, it offers a source of making a living, and support to the sick, that no other occupation does. The labor and work is of such a fascinating kind that it can be continued as a toy, year after year, for weak and sick, and many have found health and success in following it when everything else had failed. As a combination with fruit-growing it can not be excelled. In fact, every one who lives in a locality where there is plenty of bee-pasture should keep bees if the locality is not already overstocked. There is nothing that will pay better, and bring such rich returns to the health of the family.

My friends, it has been nine years since I was first elected president of this body, during which time but one union of great boasting us in a few months ago that we leave you as such, and another must take my place. Whoever it may be it should be one who has plenty of time to devote to the interests of the society, and who is able to spend a little money in the interest of the society. The work of the apiarist is like that of the front rank men or work is a labor of love in its behalf. This and kindred societies can only be kept in the advance guard by the personal devotion of those whose hearts love the society and the calling it represents. The meetings which we have held during all these years have been pleasant and profitable to me. I have regarded you all as my friends; I have tried to do my duty, and have found you all ready to assist me; and I shall be pleased at all times in the future to hear of you brave and industrious men. In whatever capacity I can be of any service to any of you in any capacity it will make me happy to serve you, and I shall also be happy to hear from each one of you personally at all times. If there is any wish that success and happiness may follow each one of you always.

J. P. WEST.

The address was well received, sympathy expressed for the president in his illness, and regret that he was unable to attend the meeting. The secretary was instructed to express the warm sentiment of the Association toward him. The proposition to join the National Bee-Keepers' Association in body was carried, and certain changes which would have to be made in the constitution if this were done, was decided to postpone action until the next meeting.

Mr. Long fellow, a Minneapolis commission man, next gave a talk on shipping and selling honey. He said he best packages to use in this market for extracted honey are the 10-pound and the 60-pound tin cans; and for comb honey, 12 and 16 section cases.
HOLDING QUEENS AND CELLS BETWEEN THE LIPS.

Doubtless perfectly dry lips will do no harm either to a queen or to a drone; but, on the other hand, however, the human saliva is a poisonous fluid (greatly variable in the degree of its poison) and we don’t want our queens soaked in poisonous fluid, as bunglers would do it, should you tell them to hold queens that way. Even for delicate plants and seeds the saliva is not desirable. Try it on nails, which can give and take in the matter of dirtiness and poison. If a high and refined degree of dirtiness is desired, with a spice of danger thrown in, try nickels and pennies. Page 256.

AN APARIAH ROBINSON CRUSOE.

Mr. H. T. Hanna, we shall have to compliment you as an aparian Robinson Crusoe, if you have a good location and no other apiary for eight miles. Page 285.

THE BEE-KEEPERS’ CLUB FOR QUEEN-BEARING.

To have 100 bee-keepers club together and employ an expert queen-bearer at fair wages to rear 50 for each, is a decidedly new departure. Certainly there are some very manly and intelligent bee-keepers out there, but, at least a place of a giint for queens. Reasonable in the place of unreasonable dates. Fair and turn and “divy” in the place of clamor—or would the order of precedence be a specially hard thing to adjudge with unifc Fathers? There are also some weak points. I think I would rather collect my wages from one man than from a hundred. And, while the enlisting of half a dozen in the new scheme might be very easy, the five thousand might be pretty well worn out before man No. 100 “swore in.” Page 291.

FIRE AT LONG-TONGUED QUEENS.

I’m right glad Mr. Doolittle fired himself off as he did on page 293. Little guns are excellent for many uses; but when an enemy develops that needs (badly needs) to be intimidated somewhat, then the heaviest gun in the service is just the piece to turn loose. Exactly how much good will come of the cultivating of long tongues by beekeepers we don’t know just yet. Quite a bit I hope (notwithstanding the “bang”), but it’s plain to be seen that inaccuracy, and pretense, and conjectures that hardly amount to more than pretense, were getting the thing as the smoke of the pit. Long-tongued bees were given to the best of my knowledge as much as “pure white,” “pure black-powder,” or “pure gum drops,” where many officers look after frauds. Attention, ye buyers! When you get your long-tongued queens, get them with the same carefulness as if you had won the first, with a great house. Testing the actual reach of bees at work is not so hard as to be beyond the reach of the ordinary apiarist; and ‘speaks it will have to come to that. Mr. D. pushes things too far in claiming that long tongues are of no profit except in red clover regions. Many long-tubed flowers have something to do with furnishing the total of nectar supply.

The Home Circle.

Conducted by Prof. A. J. Good, Claremont, Calif.

THE TOBACCO HABIT.

Over 100 of our college folks—almost half of us—went to Los Angeles last Saturday to attend the Intercollegiate Oratorical Contest, and the second contest of three arranged with one of the colleges to decide who were champions in baseball. I was proud, as our fellows won the trophies in the exhibition game, as well as they had in the first, with a great score of 15 to 2. I was still more proud as we achieved victory in the oratorical contest. But I was most proud of the gentlemanly character of our students. One way this was shown, was in the entire absence of smoking among our fellows. The others smoked. We did not. I rejoice that we have no smoking at our college. I wish tobacco was enforced in all our colleges. "Our Homes," has done splendid service in urging against this habit. I wish I could be like happy in these "Home Circle" columns. To the hundreds of students that I have taught physiology, I have always spoken, as best I might, against all use of tobacco.

The money spent for tobacco—though to my mind the least weighty argument against its use—should be thought of. The sun is enormous. If saved, how quickly it would pay off. How often would clothe our people. How generously it would "bread and butter" us all. I would might say the blessed word that would stay this frightful expenditure.

The worst count that perhaps can be brought against this arch enemy of the well-being of our people, and especially of our youth, is the tendency of the habit to make its patrons thoughtless—regardless of the comfort of others, and thus to destroy the gentlemanly bearing. How often in public places our ladies must endure the poisonous fumes from cigar or pipe. Only a few days ago I was presiding at a large picnic gathering, where speaking was going on, when some ladies appealed to me to relieve them from such an annoyance. I have had to do this unpleasant duty over and over again. Can people acquire the tobacco habit, and preserve their gentlemanly instinct, all unimpaired?

There is a very serious side to this question—that of heredity. If, as many of our best scientists insist, the taste, inclination, and diseased tissues consequent upon the use of "the weed," are all likely to be transmitted to the dear children, then how can any of us acquire—how can any of us persevere, in this, oh, so common habit? If, as seems proved, wives and children are seriously poisoned by simply breathing the emanations from fetid breath and befouled clothing; then, indeed, we have most eloquent appeal to the moral strength that can to stay this evil. And sell our girls as well as boys. God be praised that our girls are saved from this danger.

But the girls have a proud privilege. They can influence against the "weed" in a manner desired, by protecting their happiness and well-being. God help all our girls to say boldly, "Yes, the cigar is offensive to me." For surely it must be offensive, morally at least, to every right-minded girl.

THE BOYS.

I read a pathetic account yesterday of a boy, just at that awkward age of 13, who was the victim of neglect and ridicule of his sisters. Home, that should attract, almost drove him away. One of the sisters heard a lecture on the perils of smoking, and he became hardly quick. She went home, surprised her brother by the request to tie his necktie, and soon more by a present of a beautiful one. Within a day or two the big, awkward boy forgot room neatness, five other dainty attractions, which only the deft hand of girls can fashion. Wasn’t the sister paid when the great boy threw his arms about her, and blubbered out, "Oh, but it’s good to have a sister care for me." We would all like to practice one kind of theft. We would all like to rob the slums, the saloons, the street corners, and all other questionable resorts, where the dear boys are led to the bad. Loving attention at home, the words of kindly sympathy, the neatly fixed place in any plan that is dear to the boy, will almost always result in this blessed robbery. The sister almost more than mother can be the proud agent in this worthy work. From 12 to 15 is the rapidly growing, forward, blundering, bashful age with the boy. This is the time of sunshine. Let all in the home circle unite in the effort to make the boy, that it may be a good crop.
QUEENS!

Improved Golden and Leather-colored Italian bees, with assurance.

We have one of Root's best long-tongued Med- con Breeder for Queen, a Golden Bred from a Doolittle, via a Golden Bred from the U. S. over $8 each, this is worth that sum. The above breeders have been added to our already improved strain of Queens, and the colony owners, J. L. Gundy, of Humboldt, Nebr., wrote us on Aug. 5th, 1910, as follows: "Of the four bee hives that we had one of our queens had already stored over 400 pounds of honey (mostly comb); he states that he has observed that his bees work on Red Clover, as they were the only kind in his locality and adopted them.

A. Root's folks say that our queens are extra costly breed and selected. The American Bee Journal tells us that he has good reports from our queens from time to time. We have been upon the same terms from the beginning.

After considering the above evidence, need you wonder why our orders have increased each year? Give us a trial order and be pleased. We have years of experience in raising and rearing queens. Safe delivery will be guaranteed, and instructions for introducing sent with each lot of queens.

QUEENS NOW READY TO MAIL.

Prices before July 1st:

- 3-lb. Tested $1.75
- 5-lb. Tested $4.00
- 10-lb. Tested $8.00
- Extra selected tested, the best that can be had, 40.00

For 

Folding Address, your price printed on two colors, $4.00 per 1,000; $5.00 for $2.75. Address all orders, R. G. QUIRIN, Parkertown, Ohio, to American Bee Journal Office.

Red Clover Queens

Long-Tongued Bees are Demanded Now.

One Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with $0.50 or, one Tested Queen FREE as a premium for sending us FOUR new subscribers with $4.00).

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us this season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy. He imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

All queens guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

Cash Prices of these fine queens will be as follows: Untested, $1.00 each; Tested, $2.00 each. Send all orders to

GEORGE W. YORK & CO., 144 & 146 Erie St., CHICAGO, ILL.

up all their stores, and I have lost 15 colonies through spring dwindling, and expect to lose more. I have been feeding, but the bees are not ready to build up.

I think there is no better country in the United States for all purposes than the Cherokee Nation country.

—R. F. CAMPION.

Cherokee Nation, Ind. Ter., May 10.

The Weather Hard on Bees.

My bees were in splendid condition in March, breeding up strongly, and they worked three days on maple blossoms, the trees having the finest amount of bloom on them than I ever remember seeing, the blossoms being as large as peach-blossoms. But suddenly the weather turned cold, and thousands of the poor little bees were caught napping, they could not get to the flowers, and perished. The frost killed all of the bloom that was far enough advanced to be affected, and all through the greater part of April we had cold rains and frosty weather, then there was a great profusion of fruit-bloom: but the bees did not seem to be strong enough to take advantage of it, and in the midst of it came a heavy, cold rain and hail-storm which destroyed the bloom.

The bees have had a hard time of it, though most of them are in good condition now. Some are weak, but most of them are clustered at the entrances waiting for white clover, which is looking first-rate, and there are a few blossoms here and there.

We have had no swarms so far this year.

—D. C. McLEOD.

Christian Co., Ill., May 27.

Bees Starved in Iowa.

A good many of the bees in this part of the country starved last winter. I have 30 colonies in very good condition, and increasing fast.

I clip all queens, cut out queen-cells, give plenty of room—two or three supers at once—and have very little swarming. I sell all my honey in the home market, and stamp every section.

—GEORGE C. DUGG.

Bees and Olives.

These are suggested by W. A. H. Gillasp in the Bee-Keepers' Review, as a desirable combination.

He says:

The bulk of the work with olives is done between Oct. 1 and March 1; and for the first two months the work is moderate with both bees and olives. Some time in June or July the honey harvest commences and lasts until Oct. 1, when the fruit is ripe. By that time one man can put in his time the year through at one place, having no idle spell. Perhaps that is why the results are better in Greece, where they use the method in some cases, while in other surroundings, with other men, it would not.

Smothering a Colony of Bees.

This is a much easier thing than the novice would suppose. Nearly every one must suffer a personal loss in order to learn the lesson. Possibly some may be induced to be careful without any personal experience by reading the following case reported by Dr. C. S. Phillips, in the Southland Queen:

I want to tell you how we lost a large, fine swarm. There was a warm front that came out and my wife hired them, and they came out and went back. They did this two or three times, and the last time was on Saturday, and when I came home from the office she told me of it. I said, “All right; I'll fix 'em. Sunday they will not come out.”

So Sunday morning I got some wire-cloth and fitted it over the entrance to keep them.
After 28 Years.—We are not much in sympathy with the extravagant claims as being "biggest," the "best on earth," "none so good," etc. When, however, these or similar claims are based on the actual facts we believe that the advertiser has not only a perfect right, but that he should make the facts public. This is brought to mind by the advertisement of the Elkhart Carriage and Harness Manufacturing Company, of Elkhart, Ind., which regularly use this paper in season. These people for several years have been laying claim to being "the largest manufacturers of rhe classic style and the best in the market" by writing to the consumer exclusively. To one who will take the pains to investigate, or who is better informed, it is possible, go back and look over this institution and examine their methods of doing business, this statement will appear as modest and entirely within the bounds of truth and fair dealing. There is no secret about this statement; in fact, it has taken more than 28 years of hard and persistent effort to bring this institution up to its present high plane. Having de-

Honey and Beeswax

Market Quotations.

Chicago, June 7.—No new honey comb has been quoted in the market. Producers' promises are being made for some before the month closes. A little good white comb still on sale at 50 cents per pound, but very hard to find, and other kind there. Extracted very dull, practically no sales made. Suger content 80-90%.

R. A. Burnett & Co.

Detroit, May 21.—Fancy white comb 14½ pounds, No. 1, 130 cents; dark and amber, 160 cents, Extracted white, 160 cents, Beeswax, 27½ cents.

We have little desirable honey in sight. The new crop will find the market well cleaned up. The demand is always light at this season of the year.

Cincinnati, May 17.—No demand for comb honey, also stock of it well exhausted. Extracted very dull, sales are more or less forced; lower prices from 3½ to 1 cent per pound.

G. H. W. Wheler

Boston, May 21.—Our market continues dull on honey with very light stocks on hand. Our normal prices are as follows: Fancy I-pound cases, per case, $3.40; No. 1, 3.85; am-

New York, June 1.—Extracted honey is ex-

Batterson & Co.

killed by dust and very little moving. We quote for the present: White, 65c; light amber, 75c; medium, 85c; dark amber, 95c; brown honey at unchanged prices. New crop is now coming to hand, however, and from the same district as from 12½c, according to quality and style. Beeswax, 27½ cents; Hildreth & Segerin.

Albany, N. Y., June 1.—Honey market quiet.

No stock, no stock orders, and no demand now. It is between seasons. We look for good prices through the coming month. Our comb honey has very little brood has nearly exterminated the keepers.

Buffalo, May 21.—Very light trade in all grades of honey. Strictly fancy sells fairly, at 7½ cents; dull at very low rates; 3½ cents, all the range. Beeswax, fancy, 27½ cents; dark, 20 25c.

W. R. Cronkwell Produce Co.,

Successors to C. C. Clemons & Co.

San Francisco, June 1.—Honey market rather firm. 12½ cents; amber, 18½ cents; dark, 68½ cents. Ex-

market. Beeswax, fancy, 27½ cents; dark, 20 25c.

KANSAS CITY, May 4.—Practically no ship-

ments arriving, and very little selling. We are getting $3.50 to $4 per case of 24 boxes. No. 1, $4.50; No. 2, $3.50. Sugar content 85%.

ILLOIS DAY
at the Pan American Exposition.

Tuesday, June 25, 1901, has been selected by the Governor of Illinois, as "Illinois Day," at the Pan-American Exposition at Buffalo. In order to make that occasion a greater success, the Nickel Plate Road will lend its assistance by making the following rates:

$13.00 for tickets good 10 days.
$16.00 for tickets good 15 days.
$21.00 for tickets good 30 days.

Tickets at above special rates will be available on any of our three through daily express trains from Chicago at 10:35 a.m., 2:30 p.m., and 10:30 p.m., which carry through vestibuled Pullman sleeping-cars and afford excellent dining-car service, on the individual club meal plan, ranging in price from 35 cents to $1.00.

For further information and illustrated descriptive folder of the Pan-American Exposition grounds, write John Y. Calahan, General Agent, 111 Adams St., Chicago.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one on his coat-lapel, as it will cause people to ask questions about the busy bee, and many a convert is made of the same. I see it wind up with the sale of more or less honey; at any rate it would give several a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

Mr. F. Greener, of Ontario, Co., N. Y., writing us June 9, had this to say:

"The season so far has been exceptionally unfavorable. Hence we have not seen steadily, as we look for a yield only from buckwheat later."

Dr. Jas. McLean, whose interesting article on "Medical and Nourishing Properties of Honey" appeared on page 384, writes us that a slight error occurred therein, referring to the indulgence formula regarding the quantity of honey, which should be one teaspoonful instead of one tablespoonful. He thinks it might be well to rearrage the whole sentence as follows:

"One teaspoonful of pure honey dissolved in a glass of cold or tepid water, into which mix one teaspoonful of thinness of myrrh, to drink shortly after eating."

Mr. Thaddeus Smith, whose picture is shown on page 389 this week, is a retired bee-keeper, though he has from 10 to a dozen colonies. He begins, in this week's number, a series of reminiscent articles which we have no doubt will be read with much interest by all. He is between 70 and 80 years old, though no one would believe it if compelled to judge from the picture alone. It must be that the Polhe Island climate, in connection with a luscious fruit diet, contributes to longevity; and very likely honey also plays an important part in helping to keep him so young in appearance.

Mr. J. M. Rankin, as previously announced, is the recently appointed inspector of apiaries for the State of Michigan. We are pleased to present so good a likeness of him as on our first page this week. He is 36 years of age. He began his career as a bee-keeper at the age of 12, with two colonies, one in a Simplicity hive and one in a box-hive. During his first experience he made the acquaintance of a German bee-keeper by the name of Andrew Hunt, to whom he is indebted for careful and interesting teaching, and for a great deal of his early training in bee-culture. When 18 years of age Mr. Rankin met foul brood for the first time, and it resulted in the loss of half of his 40 colonies, but the disease was finally stamped out.

He took charge of the experimental station apiary at the Agricultural College of Michigan in April, 1894, and during the past four years has been a student there. He has done some good work with foul brood, and has gone several times to different parts of the State to assist bee-keepers in treating their apiaries to rid them of foul brood, so the work is not entirely new to him.

We had the pleasure of meeting Mr. Rankin at the Chicago convention of the National Bee-Keepers’ Association last August. We feel that Michigan has made no mistake in appointing him to so important a position in the interest of bee-keeping. He will not disappoint those who looked hard to secure the foul brood law, and who also recommended his appointment. On account of his investigating turn of mind, and decided interest in the subject, we bespeak for Mr. Rankin an honorable career in the bee-keeping line.

The Bee Journal is sold for 25 cents a year, and subscriptions sent postpaid. Address, GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.
Editorial.

The Season seems to be unusually unfavorable. Cold and dry weather has prevailed over a large area, while some portions complain that it has been too wet. There is some complaint that white clover is plentiful, but that the bees get little or nothing from it. Unless very close watch is kept, there is danger that some colonies will be starving in June.

Starting Bees in Sections.—Mrs. Barber and others are warm in praise of the plan of giving bees an extracting-super to start them to work, and a day or two later replacing the extracting-super with a super of sections. Referring to this, M. A. Gill says in Gleanings in Bee-Culture:

In advising the use of an extracting-super to start to work in sections, are you not aware that thousands of us bee-keepers do not have an extracting-super on the place? I would advise any bee-keeper working for comb honey to exchange supers with colonizers that are tardy about working in sections with one that has made a good start, and be sure to carry along some of the comb-builders (young bees) which are the last to leave the super. The colony, given the super with full sheets of foundation will at once resume work, from the force of the same habit you say they have acquired by the use of your extracting-super.

A Satisfactory Hive-Cover—at least one that is satisfactory in all climates—is hardly yet on the market. Editor Root says that the perfect hive-cover is yet to be made for Colorado, Cuba, and other countries that are different from the northern part of the United States. He hardly need to have made any distinction, for objections against a cover in Colorado would still lie against it in New York, only in less degree. Possibly one trouble in the case has been that there has been too strong a feeling that the expense of a cover may not much exceed the cost of a plain board. Something must not be expected for nothing, and a good cover being so essential a part of a hive, the wise bee-keeper will hardly object to some extra expense. Perhaps it would be a good idea to have a pretty thorough discussion as to the points of a good hive-cover. Some of them may be as follows:

Lightness: a cover must be lifted a good many times, and it makes a big difference whether it weighs five pounds or twenty-five.

A freedom from warping and twisting: a plain board cover may be firmly nailed at the ends that it cannot possibly warp, but the cleats can not in the slightest degree prevent it from twisting so it will not lie flat on the hive.

A dead-air space: this will make it cooler for summer and warmer for winter. To be sure, a shade-board can be put over in summer, and something of the same kind may be effective for winter, but it is more convenient and satisfactory if cover and shade-board can be all in one.

A hive-cover with these requisites would make a perfectly close fit, and, if made properly, give pretty good satisfaction. In spite of the expense, some have covers coated with tin, so as to make a sure thing against leakage. Lately Neponset roofing-paper is mentioned as a close competitor of tin. Gleanings in Bee-Culture reports it is still doing good service after 12 years' use. Of course, it must be painted; but so much tin.

Improvement of Stock is in the air nowadays. Unfortunately it is "in the air" in too literal a sense. There is a general reaching out after it, and a feeling that somewhere in the air about us there is something like improvement if we only knew enough to get hold of it. We are just now getting along so far in the matter as to begin to realize that we know nothing about it. The editor of the Rocky Mountain Bee Journal says:

"Who among us will deny that darkness, black as Egyptian night, envelops the whole bee-keeping world on this subject? This includes queen-breeders, bee-journal editors, and all others."

Well, it is a hopeful sign when one begins to feel his ignorance, and the reaching out after light gives promise of good things to come. If control of mating becomes an established fact, why should there not be just as intelligent work done in breeding bees as in breeding any other class of stock? Even without control of mating, if enough interest can be aroused to get all the bee-keepers to breed only from the best, there will be a great gain.

Sections Filled with Foundation have an argument in their favor sometimes not thought of. If you are wise, you will probably have in the brood-chamber much less drone-comb than the bees desire. It is the natural thing for them to fill out largely with drone-comb for storing, and the two kinds of comb do not look so well in a section. You probably have thought of that, but that is not all. The bees desire drone-comb, and if you keep careful watch you will find that sometimes as much as half or quarter of the section has not a drop of honey in it when sealing is well along in the super, because the bees are holding these cells open for the queen to lay in. If the section is filled with worker foundation, then there is no chance for drone-comb there. Those who use full sheets of foundation in sections do not find it necessary to use excluders to keep the queen down.

Size of Entrance.—Editor Doolittle says in the Progressive Bee-keeper that he regulates the entrance to suit the size of the colony. After the season upon which she obtained her allows to the strongest colonies an entrance of 2½ inches, and from there down to 1½ inches for the weakest, leaving them thus during early spring. When the bees begin to work on early pasturage, the entrances are enlarged as needed to allow free passage.

Box-Hives and Skeps in other countries seem to be more common than in this. A writer in the British Bee Journal says: "I can get as many driven bees as I like for the trouble of "driving."" The writer says he makes his hives out of used boxes, and he has taken the first prize for the best hive made by an amateur. Most bee-keepers on this side would hardly feel they could afford to make their own hives from common boxes.

Yellow Sweet Clover.—Successive crops of this clover from one sowing are reported in Gleanings in Bee-Culture by M. M. Baldridge. December 2, 1887, seeds were put in a shallow trench and covered with one or two inches of soil. From this sowing came three distinct crops, the last in 1899, which must have come from the same sowing. He says it sometimes winter-kills, and, like the white variety, it is a biennial.

Getting Light Extracted Honey.—Mrs. Harrison tells in Gleanings in Bee-Culture about some extracted that she put on exhibition in competition with a number of other samples, the best among which she obtained a premium. Hers was distinctly whiter than the others, which did not at all differ from each other. Her competitors thought there must have been some trick about it, and she told them the trick. She extracted from none but pure-white combs. Holding the comb up to the light, if she saw a few cells of dark honey, those few cells were not unpicked. All utensils were clean and free from other honey. That was her "trick" for getting the whitest honey. This trick is a familiar one across the water, but bee-keepers on this side are hardly equal to their foreign cousins in getting up extracted honey for exhibition.
Convention Proceedings.

(Continued from page 376.)

BY DR. L. D. LEONARD.

SECOND DAY—Afternoon Session.

Mr. Corbett, of the Dairy and Food Commission, talked of the work done by that Commission in the State. Of 150 samples of honey examined in two years, 25 percent has been found to be adulterated. Four dealers have been prosecuted for selling adulterated honey, and fined to the amount of $55. The following letter in regard to the matter, was read:

Hon. J. P. West—

My Dear Sir:—Pursuant to your request to Major Bowler, I send you the following names of those who have been convicted and fined for selling adulterated honey this year:

Sahmaus & Zeigler, Duluth, Feb. 23, 1900—$15
Ol A. Berz, March 12—$15
Mallouh & Son, March 15—$15

The second named was fined for selling imitation honey.

Yours very truly,

A. Grindall.

Miss Moeran then gave a talk on cooking and canning with honey.

The advisability of having a Minnesota honey exhibit at the Pan-American Exposition, at Buffalo, was next discussed, and Dr. E. E. Jaques was appointed to take charge of the matter for the Association.

The following paper by G. H. Pond, was then read:

DISPOSING OF THE HONEY CROP TO THE BEST ADVANTAGE.

In considering this subject we must first decide whether we want to get the most for our honey regardless of the time required; or, is our time worth so much that it is best to sell our honey the easiest and quickest way? If we come to the latter decision the bee-keepers of Minnesota have an excellent outlet for their honey through the commission merchants of Minneapolis and St. Paul; and I think we can obtain better prices for our honey through them, than do those who ship to the large Eastern cities.

But perhaps most of us will decide that our time is not worth so much that we feel warranted in following this plan, and if by spending more time in disposing of our crop we can get a better price, we would better do so. Now I do not propose to advance a theory, but to give a few facts from experience, and as I have had no experience in producing or selling comb honey, I shall dwell only on disposing of extracted honey.

Honey is an article that people in general do not buy unless it is brought to their notice, so, in order to sell it, is necessary for us to put it up in a very attractive way, and then bring it to the notice of the people as much as possible. In peddling honey among farmers I have found that the fether I go, the more I can sell; and this rule holds good wherever I have sold honey. "Keep going" is a good motto for any one who would sell bee-honey, for customers nearly always tells a friend or two, and shows them the honey, and in this way the business is extended, so that the more one sells the more he can sell.

I have learned by experience not to try to induce people to buy more honey than they wish at one time, because sometimes when they buy too much honey, or gets in an untidy condition otherwise, and thus they get set against it. It is strange how many people there are (who ought to know better), who think that when honey candies is spoiled. For example, I have sold to many people boxes of honey for two or three years and they take over 100 pounds at a time, getting it three or four times a year, and I supposed how to care for canned honey. But this fail their kitchen-man, and he thought he could get much money from it, and on examining it I found that all that added it was that honey was stored. A new kitchen-man was employed and he did not understand it.

In selling honey put up in glass packages to retail grocers, I find that if the honey candies on their hands their sales of it about come to a standstill, and although I tell them that heating will restore it to a liquid form, and they say that they will try it, I do not remember that a single one of them ever did. I have found that the best way is for me to exchange it for honey freshly put up, and take the candied home and relish it myself.

To sum up, then, the most important points in disposing of your honey crop are:

1st. Produce a first-class quality of honey.
2d. Put it up in as attractive form as possible.
3d. Bring it to the notice of customers constantly.
4th. Keep your customers satisfied.

C. H. Pond.

Next, a paper was read by Dr. Mary McCoy.

BEE-KEEPING NEAR DULUTH.

Years ago I became interested in the bloom in and about Duluth, as a possible profitable field for the support of the honey-bee. The spring season of Duluth is always short; three weeks later than that of the southern part of the State, our earliest bloom being the dandelion, which is an abundant producer of pollen and some very bitter honey that is claimed to be very stimulative. We have some fruit-bloom—apples, cherries and plums—but there are not enough trees, all told, to make a fair-sized orchard. I do not think that basswood is indigenous to the country about Duluth, and there are but very few trees planted in and about the city. Until this year, summer butternuts have made very few flowers, and I have always ushered in the white clover which formerly literally carpeted the whole surrounding country, as well as the vacant lots, squares and parks of this city. Wherever a fire has burned it has been replaced by deadened foliage and blackened foliage with a profusion of the fragrant white clover bloom, and as Duluth has only recently been reclaimed from a wilderness, and fire has been one of the reclaming agents, it has had plenty of barren spaces, neat and beautiful. There are a few other flowers, such as the wild strawberry, the wild cherry, and the wild rose, which all help very materially, and I could not help noticing how heavily the wild cherry-tree bore which grew near where the bees were placed.

In the early fall the fireweed puts in an appearance and the honey stored from it is as fine as that from the white clover.

The weather is cool enough here so that the bees do not care to hang outside of the hive, and the first summer we kept them they did not lose more than one out of every six days.

The past summer was a little warmer, and they loosed a little in the middle of the day, but their loss is not to be compared with what I have seen of it in the Michigan apiaries.

We have had no experience with any bee-diseases in Duluth and have seldom had any where we have lived; but I think the bee-moth inhabits Duluth, or, if it does, perhaps the bees (like the people of our city) are too wise to make it a foothold.

Suffice it to say that since the first summer that we have not caught the disease, we have never lost more than two or three colonies.

We know nothing about foul brood; it is a disease that has not yet gotten into our part of the State. I don't think there ever has been any in this section, and I hope there never will be.

There are about 10 people in and about Duluth that keep bees. One family has kept them over 20 years. I asked the head of this family—she is a widow—if it paid, and she replied, "Well, I've paid off the mortgage on the farm, sent the children through high school, and one through business college, and built a kitchen on the house, and all I've had to do it with has been my 69 colonies of bees." So she has found it profitable.

We have been keeping bees for about four years, starting with two colonies. White clover began to blossom about May 15, the spring being unusually warm and early, and as we had plenty of rain throughout the summer, and the frost was late in appearing, our honey season lasted till September. That is, until we sold out, for we sold out our 175 pounds of beautiful white clover comb honey, which was selling in Duluth at that time at 15 cents per pound.

The next summer the yield was fair, but as the bees were five miles from our home they were hungry and I supposed they should have had, although we increased to 12 colonies, and secured about 300 pounds of honey. We had scarcely any snow last winter [1899-1900], and the white clover was badly winter-killed, so we did not have the honey; although we sold none at all; but if clover was scarce, the price of honey was high, so we did not do so badly, after all. We sold one colony to a friend, and with the honey we sold and ate, we figured that our debt and credit sides have come out about even. We discouraged swarming all we could the past sum-

Contributed Articles.

No. 1. Some Reminiscences of an Old Bee-Keeper.

By Thaddeus Smith.

I propose to give some recollections of the time, incidents, and persons, connected with bee-keeping over a quarter of a century ago, and some incidents of my own personal experience of 30 and 40 years ago, with notices of prominent contemporary bee-keepers and the great changes and improvements made in the science of bee-keeping within the last 25 years. The introduction of the movable-comb hive, and the Italian bee. This first article will be given to the writer's early experience and the condition of bee-keeping at that time, but in future numbers he will give the more up-to-date accounts.

I was brought up on a farm in Woodford Co., Kentucky, ten miles from the city of Lexington, and as far back as my earliest recollection I have been at the hives of small and queenless colonies that were destroyed by the moth. Such is undoubtedly a fact where movable-comb hives are used, and some assistance can be given the bees in getting rid of the moth, but it did seem, in those days, that some of the colonies would succumb to their attack.

It has been said that wherever there is a demand there will be a supply. So we soon had offered us patent mothtraps, and patent moth-proof and moth-catching bee-hives. Agents with models, beautifully made of mahogany or rosewood, perambulated the country. The worms, perhaps, were not so long lived as these things "worms"—I may learn after a while, but excuse me for the present), when matured or dislodged by the bees, would fall to the bottom-board and take refuge under the bottom edge of the hive, and under the combs that came near the bottom, and I had to go early every morning and tilt the hive back and kill the worms. This was a pretty good non-patented mothtrap, but required close attention and work, accompanied sometimes with burning.

My father set about to devise a better plan to get rid of these worms that fell to the bottom-board, and to break up their hiding-place and prevent them getting up into the combs again. He had the hives all raised from the bottom-board by driving a big nail in each of the four corners, leaving them to project three-quarters of an inch, forming an entrance that high all around the hive. These he set apriaries looked as if they would be destroyed by them. We did not know then, as we know now, that it is only the weak and queenless colonies that are destroyed by the moth. So there could not have been much trouble in wintering.

But there came a time, for a number of years, when the moth worm or miller became very bad indeed. Whole...
upon smooth flat stones, that were easily procurable, from one to two inches thick, and laid flat on the ground, distributed all about over a large yard. Now when the worms fell to the bottom they had no place to hide, could not get back on the combs, so had to go to the ground, and many of them were eaten by the other insects. Brown and white house-wrens were often seen busy around the hives gathering these worms for their brood.

My father tried other projects—had hives placed in a house, and had the entrance to them through long flat tubes extending a foot or so outside the walls of the house, so the moth-fly could not find her way into the hive, I suppose. He had a theory that it was necessary for the worms to have access to wood for material to form their cocoons with, as we often see them scrape and cut into the wood of the hive to enclose themselves; and he got the idea of having hives made like common crockery or stoneware, but not being near to any crockery manufactory he failed to try the experiment. The hives placed upon the stone with an open entrance all around that was never closed or contracted, winter or summer, seems to have given the best satisfaction, for they were used in that way until I adopted the Langstroth movable comb hive in 1863.

I remember some curious devices of my neighbors' One had a hive suspended by chains in a tree some 20 or 25 feet from the ground—to imitate the natural abode of bees in hollow trees, I suppose. Another had a bee-house with arrangements for getting surplus honey from below the hive instead of the usual way from the top. A trough-like box 12 by 14 inches square extended around the inside of the house, and bees were placed in and over it, and upon this box the hives were set, the bees having to pass through the box to get out. When they had filled the hives, they would fill the box below, and a trap door was arranged on the box so the honey could be cut out. He claimed that it worked well.

There was another curious bee-house in his front yard. It was a section of a very large hollow sycamore tree, probably four feet in diameter and six feet high. It was placed upon a post a foot above the ground with a floor in it, and a neat, conical roof of shingles, with a staff in the top, and was quite ornamental. A door was sawed out and was so placed that one could go into it; and in it an ordinary box-hive of brood was placed. When the place was filled the box they would build comb all over and around the outside of it. The door to the big "gum" was opened, and the honey outside of the hive cut off whenever needed, or as cool weather came on. I don't know whether this colony ever swarmed or not. Ontario, Canada.

To be continued.)

Bee Keepers' Exchanges—Organization and Co-operation.

Written for the Wisconsin State Bee-Keepers' Convention held at Madison,

By C. A. Hatch.

We have so often heard it said, "In union there is strength," that it has lost its power to affect our understanding. A single straw would not be much to match against a man's strength, and yet if that single straw be increased by numbers enough it can defy the strength of the strongest man.

An army would not accomplish much if each soldier were allowed to go and do as he pleased regardless of every other soldier. But if all act uniformly, and become a unit of the whole, that it becomes an army and ceases to be a mob, that effective work can be done, and it becomes a power.

ORGANIZATION.

Concentration and organization are the effective means of progress in the beginning of the new century. Unorganized labor is being pushed to the wall by organized. The strength of a man is not in his confidence, trust, or some thing of the kind, has a hard row to hoe. He may make just as good an article, and may be able to sell it for the same price as the trust article, but then comes in the item of freight-rates which is sure to down him if nothing else will. The large concerns have larger quantities to move, and therefore can ship by car or even train load, thereby getting lower rates, to say nothing of treaties with rail-roads whereby special rates may be obtained.

WHOM IT HELPS.

The small bee-keeper with only a small output is the one that an exchange can help most. He is one of the small straws that are to be bound together to make the strong rope. Ten men having one-tenth of a car-load each, by organizing, can have almost the advantages of him who has a car-load and himself. The large producer gains by having small lots where they can be controlled, and not put on the market at ruinous prices, to demoralize all prices.

Bee-keepers are of necessity more or less isolated, and hence can not avail themselves of the help of organization as readily as some other callings. But even these difficulties can be overcome.

ADVANTAGES.

The advantage of lower freight, both on goods shipped by members and goods shipped to members, is one of the advantages of bee-keepers' exchanges. Also the difference between buying at retail and in car-lots or large quantities is another advantage. This will apply to all supplies used by the members, as, for example, hives, sections, foundation, cans, and barrels.

Another of the advantages of a well-managed exchange is in the uniform grading of the bee-keepers' products. Few men are capable of grading their own honey in a proper manner, for they are either too partial to come to a fair judgment of their own products or too deficient of their own success and modestly put it too low, and yet others are downright dishonest and think anything they can work off is all right; whereas, an honest, capable grader has none of these influences to draw him one side and his judgment and care can give a fair and honest grade. One of the trials of a dealer is in not getting a uniform quality from different producers, owing to their different ideas as to grading, and if an exchange could do nothing else this one thing would pay for all the trouble.

Not every bee-keeper, however good he may be at producing good crops of honey, is a good salesman, many a bee-keeper losing heavily in mismanagement in selling what he can, and him self.

In an exchange one can have the advantage of the concentrated wisdom of all the membership in selling, by selecting one of the best business men for business manager.

Uniformity of packages for both comb and extracted honey is another of the benefits of an exchange; being all bought at the same time and place, of course all would be alike, and, therefore, many of the trials over tare on packages would be overcome, dealers would become familiar with the packages used and would know exactly how it would come to them in. In fact, uniformity is the word that expresses most of the benefits. Uniformity of products as to grading, uniformity as to packages, and, last but not least, uniformity of prices.

One kind and grade of honey would always bring the same price, no matter from what part of the State it came, and not as it now is—one producer competing against another producer, or even against his own products, as would be the case where shipped to two dealers in the same city.

COST OF CO-OPERATION.

Everything in this life costs time, labor, or money, and a honey exchange is no exception. It will cost both money and self-denial to accomplish anything worthy of the name. Postage, mailing, prints, general correspondence, must be paid for; a room large enough to store a car-load of honey in, at some central point in the State, would have to be secured, and also the services of a salesman. But in my experience with honey exchanges, which has been quite extensive, I found all these obligations of the members are more easily met than the self-denial required to say our honey is not a little nicer than neighbor B's, our opinion is of a little more value than any one else's.

If an exchange is to succeed, there must be a full and complete surrender of individual opinion to the rule of the majority. We must think our honey just what the grader makes it, and no more. Be honest yourself, and give others the credit of being the same, and half the troubles of organization will vanish.

There are other advantages in an exchange not mentioned in this paper, and on account of its length the plan of organization has not been mentioned, although much is
Can a Queen-Bee Be Worth $50, $100, or $1,000?

BY G. M. DOOLITTLE.

Of late years there seems to have sprung, from the minds of some, the idea that if they would let the world know about a certain queen-bee which they have, the only way in which this can be done is to give the estimate they place on her in dollars and cents, that, apparently, being the only expression of value. And from this it comes about, that we frequently see in print that some have queens which they value at $25, $50, $100, and some even as high as $200; and so the question has arisen in the minds of some, if there is such a thing possible as that any queen-bee can be worth these figures; and whether such expression should be an inducement to buyers.

Commenting on this matter, the editor of the American Bee-keeper wrote as follows:

"When a queen-breeders offers as his greatest inducement to buyers to send out queens from a mother valued at 50, 100, 200, 500 or 1000 dollars, he should be regarded with suspicion. If he is not a faker pure and simple, he is not what he appears to be in the eyes of the honest business world."

And what is a faker? The Students' Standard dictionary says a faker is "a street vendor." But coupled with this is the idea, in the minds of most people, that this street vendor elligently to the utmost of his ability, to "hawk them up," rather than on the real value or merit there is in his goods, in proportion to the price asked for them. And this is the light in which the editor of the American Bee-keeper looked at the matter of selling queens from a mother having only a dollar-and-cent value attached to her, according to my opinion, in reading that editorial.

There is no abuse in calling his goods in such a way, or in any way, which will enable him to dispose of them at a large margin of profit, relying on his ability to "hawk them up," rather than on the real value or merit there is in his goods, in proportion to the price asked for them. And this is the light in which the editor of the American Bee-keeper looked at the matter of selling queens from a mother having only a dollar-and-cent value attached to her, according to my opinion, in reading that editorial.

If we take that comment alone, it is just such an argument as any faker would use, and it was just the point Editor Hill was striking at, in reading his editorial argument. And such an argument does not rise much above the definition of what a "faker" is, as given in that same editorial in Gleanings.

Unfortunately, Mr. Root comes to the rescue near the close of his comments where he says:

"The laurels of our [b800] breeder do not rest solely on the long tongues of her bees. But long tongues or no long tongues, she [her bees] rolled in the honey last year, and is doing the same thing this spring. That her bee's work is worth the yard.

In this we have something of value expressed, while the simple saying that this queen "is worth $200," without any qualification, (save that, because she has been "hawked" up as worth $200, "I can sell $1,000 worth of queens from her queen"), expresses no value, save that which comes from the wear and tear of the lungs doing the hawking.

But let us take this value part and look at it a little, and see if it is possible for a fine breeding queen to produce valuable honey (that may be exchanged for other values which can be represented in terms as high as $50, $100, $500 or $1,000.

Take a queen in any of our apiaries which gives bees the class of Mr. Hight. But if they sold 10 pounds more honey to go other colonies having common queens, that extra 10 pounds of honey, according to present prices, would represent $1.25 as food, or exchange for value some one in another city may have produced, which we desire. Then, if that queen lives three years, her bees do equally as well year, then she has a value, speaking in common terms, of $3.75, or above the average queen in the apiary, if the average queen is worth $1.00 at producing values, then this queen is worth $4.75 for the real value of her bees, just for honey-gathering. So, then, we have it possible that a queen may approach nearly to a quarter of a hundred points of value from the honey-gatherer alone.

Now let us suppose that we use this queen for the purpose of rearing other queens, that we may increase on the value there is in her bees over and above others for honey-gathering purposes. The queen may be fairly well, (according to the way I find it in my apiary), only one queen in four will prove as good as her mother. If we rear 40 queens from this one, and 10 of them prove of equal superiority over the average queen in our apiary, as did their mother, we have the value of that mother-queen estimated in dollars and cents as $37.50. Now suppose we have 4,000 colonies we wish to rear, and we go out into the world to bless it with that number and one out of every four proves as good as the mother, then we have $3,750 as the worth of that queen, from the extra value in honey the bees from her daughters bring in for the mouths of those famishing with "honey-hunger" in the world.

But can 4,000 queens be reared from a single mother? Oh yes. With our methods of rearing, it would be easy for some of our largest breeders to rear 10,000 or even 20,000 queens from a single mother. Then it is possible, by keeping this mother-queen in a nucleus of bees the rest of the time, to prolong her life to five, and even six, years, as some of our breeders can testify. And thus it will be seen that the value there is in a really good queen—one that is head and shoulders above the average of those in the country—may go even much above $1,000, as we commonly express ourselves.

But not to appear as a fakir, we should know that the queen has real value in the work accomplished by her bees and those from her queen daughters, putting that work out to the world as her real worth, rather than saying that "we value her at so many dollars."
Questions and Answers.

Conducted by Dr. C. C. Miller, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—Editor.)

Management for Increase and Honey.

I have an apiary of 70 colonies, and would like to increase them to 140 this season. I would also like to get much honey as possible at the same time (mostly extracted). I have enough brood-comb on hand to give each one almost a comb. I have had an abundance of ex-tracting-combs, and a good many sections for bee, white comb. The surplus obtained in this locality is from white clover, linden and goldenrod. The prospects for a good flow from linden are excellent. Supposing this to be your case, how would you proceed to obtain the best results?

MINNESOTA.

Answer.—I don't know what will be the best way for you. What is best for one person may not be best for another. What may be best for you in one place may not be best in another. On the whole, probably the very best way would be for you to study carefully all you can and in text-books and bee-papers so as to be familiar with the whole subject, and then block out your own plans. It may be that your best plan will be to allow each colony to send out one natural swarm. The prevention of swarming may be given so many times in this department, which may again be given here for the sake of the newcomers who will need it about this time of the year:

"Hive an old colony in the morning, and then set the hive on the old stand, setting the old hive close beside it. A week later move the hive to a new stand. That will strengthen the swarm, and it will so weaken the old colony that it will give up all further thought of swarming. Of course, the swarm is what will give the crop of honey and prevent it from being so often put between hive and super the super should be put on as soon as the swarm is hived. If no excluder is used, then the super should not be put on for a day or two for the queen may get lost.

It is possible you may prefer to make matters into your own hands, for left to themselves you are not sure that every colony will decide to swarm. This plan may suit you: Take from No. 1 all its brood-frames but one, brush- ing all, or nearly all, the bees back into No. 1. Fill up No. 1 with empty brood-frames or frames of foundation. Put the frames of brood in a hive we will call No. 3, and set No.

3 in place of No. 2, removing No. 2 to a new stand. Do this in the forenoon, unless you do it in the afternoon at a time when large numbers of the bees are out for a play-spell. For a day or two all the field-bees that go out from No. 2 to form new colonies will be so occupied that they will not leave No. 1. This frame of brood, the bees may be discouraged and the hive is likely to be filled, and if you leave it for a day or two they may swarm."

Preventing Increase—Other Questions.

1. How would it do, to prevent increase, when the bees swarm get the queen and kill her, or take her away from the swarm, and return the bees to the original colony?

2. When the bees are smoked they fill themselves. What do they do with that honey? Do they retain or re-deposit it where it came from?

3. Does it matter whether the bee-space is regular between the lower frames and the sections above?

4. Will the bees work above when the spaces between the frames and the sections are irregular, or partly closed by misfit of the sections?
may cut out all queen-cells but one, a week after the first swarm. You may listen for the piping of the young queen in the evening of the seventh day after the swarm issued, and if you do not hear her then, listen every evening till you do, or till the sixteenth evening: when you hear piping cut out all queen-cells next morning. You may hive the swarm when it issues with the young queen, and put it in the cellar till the evening of the next day, and then return it to the old hive, by that time the bees will have dispensed of all the queen-cells.

2. It is probably redeposited, in most cases.

3. It matters much. If the space is less than about ¼ inch, the top-bars will be cemented to the parts over them with propolis or honey more than about ¼ inch, burr-combs will be built and filled with honey.

4. The bees will work in the super no matter how irregular, even if half the spaces are so close together that they can not get up through them.

**AMERICAN BEE JOURNAL**

June 20, 1901.

Dealing with swarms.

If you have empty combs that the bees had died on last winter, would you put in as many such frames as the hive would hold to hive new swarms on, or would you put in some frames with only starters or foundation in them? I would use combs, Wisconsin.

**ANSWER.**—I would fill up with combs as long as they last. There is no better place for combs to be protected than in the care of the bees, and the sooner the bees get the combs the better.

### Bees Deserting the Hive

I had a swarm of bees leave a hive June 1. In the spring I transferred the bees from an old box into a new hive; for a while they seemed to be doing well, building up their broken combs, and were gathering honey. About noon June 1 they left the hive, taking the queen, young and old bees with them, and leaving unsealed fresh honey, young bees just gnawing out, and bees in the larval state. There were no mice or ants to bother them. The hive was clean, and they had plenty of honey, and when I looked in the hive there were only five or six bee robbers, I suppose.

**COLORADO.**

**ANSWER.**—I don’t know what the trouble was. It likely was a case of what is called spring dwindling. I have had colonies desert their hives just as yours did, leaving honey and brood in all stages, with no apparent excuse that I could find. If the colony is weak, and the only thing that I could guess in the case was that the old bees had died off, and there was more brood present than the young bees could take care of. You may have trouble of the same kind again, and you may not have another case in years.

### Too Rapid Increase—City Bee-Keeping

I started the season with four colonies, which, up to date, has increased to ten, and one ready to swarm. I have one colony that is working in the supers. We have plenty of white clover, and I think will get some honey soon. But we are a good quality of Italians—the best in this section. I live in the city, and don’t branch out very strong. Now, what would you advise me to do? I am a dry goods clerk, and have not much time. I can sell a few colonies now. Would it be a good idea to rent pasture close to town, and try to take care of the over-supply, or not?

**ILLINOIS.**

**ANSWER.**—It may do no great harm before answering your questions to make the gratuitous suggestion that you may make the mistake that many a beginner makes, and increase too rapidly. When you increase from four to ten or more, your colonies will not be as sure to live through the winter as if you were satisfied with a more moderate increase. Neither will you get as much honey. Of course, if you are anxious for increase, and will give them the proper care, feeding all that is necessary, you may pull through all right.

1. If the drones are so plentiful immediately after cast- ing the swarms, the trouble probably is that there is a great deal too much drone-comb in the hive. If the drones appeared in plenty not until two months or so after the last swarm issued, then the trouble may be that you have a drone-laying queen, or laying-workers. If on would is from too much drone-comb, then your bees will gather less honey than they otherwise would, and much of it will be wasted in rearing and feeding those useless consumers. If laying-workers are present, or a drone-laying queen, it means the destruction of the colony.

2. What do you want to rent a pasture for? If you mean for the bees to feed upon, they will not thank you to rent it, but will find it if it is within two miles of your home. You can keep in a city yard as many bees as can find pasture within reach.

**Bees Not Working.**

Bees are building up fast. I have a colony that has a queen, but the bees work hardly at all, scarcely any of them coming out. What is the matter? They have some honey. I will Italianize about the middle of this month. I lost heavily the last winter, because of short stores last fall.

**OKLAHOMA.**

**ANSWER.**—There may be nothing the matter except that the colony is very weak. The presence of a queen can not of course warrant a goodly number of bees flying unless there are plenty of bees present. Look and see whether the queen is a drone-layer. If not, you will probably see bees fly as well as soon as the colony is a little stronger. You should turn out that there are plenty of worker-bees in the hive, and very few of them flying while other colonies are busy, then it may be well to change the queen and give them one or more industrious stock.

**Perhaps Pickled Brood.**

I bought five colonies of bees this spring in movable-frame hives. Three of them, I looked into, and found dead bees, which looks watery, and lies on one side. There is no smell about it. It doesn’t seem rubbery, or anything like that, and will not draw out with a toothpick. Will the swarms have the same disease? What will become of soul-necrotic or pickled brood if not attended to? What can be done for them?

**NEW YORK.**

**ANSWER.**—When anything so serious as pickled brood is suspected, it is too serious a matter to be treated by a few words in this department, especially as it would take up too much room. Study up the subject fully in back numbers, and get the leaflet on pickled brood, if you do not have it already. Very likely, the sections on which you will find the disagreeable symptoms largely to disappear, but none the less you should inform yourself so as to battle it, for it will be a safe thing to count on its reappearance in the future.

**Thinks Late Thin Honey Injures the Bees.**

There is a plant here that has yielded honey in October for the last two years. The bees have filled the brood-chamber full of this thin honey, and when they had the first flight in the spring they opened the hive badly, both inside and outside around the entrance. I lost half of my bees, and the other half are weak. It seemed to affect the queens. I would like to know how to keep this thin stuff out of the brood-chamber. I lay the sections on which they had room. How would it do to run it through the extractor without uncapping it? If there would be any brood in the hive at the time would it not kill it? I believe the honey is from the sters.

**OHIO.**

**ANSWER.**—I am afraid I don’t know enough to help you out. There is a possibility that you may be mistaken about the honey from that late plant being the cause of the mortality among your bees. But if you are satisfied that extracting without uncapping would help matters, you can do so without hurting the brood. So long as you do not turn the extractor fast enough to throw out the brood you are all right.

**The Premiums offered this week are well worth working for. Look at them.**
The Treasures of Nature.

From the drift of a star to the drift of a soul,
The world is all miracle under control;
That the breath of love and man's realized awe,
Alone wear the chain of inscrutable law.
A law that attains us, but ever eludes,
That baffles our groping, but never deludes:
We never can hold it; it holds us secure;
And the wisest in reading shall longest endure;
A Faith-bow of promise, a promise replete—
As sweet as the honey-bee and as fulfilling; but never complete;
We chase where it beckons, and gather the gold,
And lo, on before us, new treasures unfold!**

THE STUDY OF NATURE.

In my teaching in college, I find in some of the students an almost insurmountable disinclination of handling insects, because they come with no alacrity to the work of dissecting. Others, no whit less refined and sensitive, in a general way, show no such squeamishness. We dissect cats at first, and then other and smaller animals. The practical zoologist and the protected, not from books but from handling the real things, as of great value. The same is true in regard to the study of caterpillars, beetles, and bugs. The distaste is often erratic in the extreme. Thus nearly every girl will take interest in, and even at first, the beautiful, little lady-bird beetles, while the same girl will shrink away appalled at a ground-beetle or caterpillar—will shudder if a myriapod is handed to her, and actually turn pale at the very thought of touching a spider. I think that all this unreasoning, and in fact, unreasonable, is a vice. It is, perhaps, no more, unless cured of it—and it is a malady difficult of cure—will lose much of the beauty that she would otherwise get. Every girl may be required, as a duty, to dress a chicken or a rabbit; to dissect carefully a cat will teach her to do the other more intelligently, and will give her an insight into her own structure and physiology that will be of great value, and which can be gotten in no other way.

The insect world touches us in many ways. They annoy us and our domestic animals; they prey upon our crops to the annual tune of millions of dollars. The best success in life demands that every home circle shall know—and so study—these myriads of friends and foes—for all are not enemies—that they may prepare to wage battle in case the intruder comes with intent to injure. Insects are ubiquitous—that is, everywhere. We run against them at every turn. Not to know them is surely most unwise. In fact, that man is best equipped who knows most about the things that he runs against in all his daily walk. The little malarial animal is very small, but it can destroy the red blood corpuscle. To know of it and its work enriches the world. To know that a mosquito inoculates us with this often fatal poison, by its bite, is even more valuable, for it shows us how we may fence off disease and even death.

Thus this knowledge of these hosts that everywhere encompass us about is vastly practical, and stupid indeed is he or she who does not grasp every opportunity to gain such knowledge.

Again, no study does more to quicken and develop observation than this. The person who sees everything, and sees it well, is mightily strengthened for life's big fight. As students work in geometry, they often say that they can almost feel their brains grow. So students of entomology often remark, on their increased facility to find insects, and to find and see correctly minute and obscure parts, as the study goes on.

Just here is suggested a duty for every home circle. I have shown before the value of the walk in the woods, the Sunday stroll with the children by wayside and meadow. These are very golden days to foster this love of nature. They are often times when it is hopelessly crushed. The mother, mayhaps, is taking her first walk with the little boy or girl. They come upon a lovely caterpillar or beautiful beetle. The mother shrugs and jumps back. The little one has a lesson and an impression that it will take long schooling to correct. It has then and there gained an abhorrence that will rob it of great pleasure, and will very likely be a handicap in life's work. I have always rejoiced that my mother was not appalled at the sight of grub or spider, and that she early taught me to see the beauty in both. I shall never involve the.planck child in this unfortunate. I hold my own little ones to admire and love these gems, sown so thickly about us by God's own loving hands. I rejoice the more as I know that my dear ones are much better equipped on this journey, and are much better prepared to get more of pleasure and profit from it.

I urge all in our home circles to be interested in everything about them, to study and observe, and I am free to say that nothing offers so rare an opportunity as these myriads of wonderful insect forms and insects. The honey-bee and myriapod, their head high, walks more erect, feels more self-respecting, is more a man. While thrill may not be, is not, the best gift to covet, it is a worthy one. So of our nation. She for many a year is vain. She shall not have all she desires, and what is, her income is far in excess of her outlay. In other words, her exports of bread-stuffs, manufactured articles, and raw materials, are far in excess of her imports—of tea, coffee, sugar, and such other articles as she needs. We are thrifty. We are industrious. We Doolittle and I are both rejoiced. We are happier than though she were buying more of value than she were selling.

I believe Mr. Doolittle is exporting in excess of his imports. That is, his home-sales, etc., are greater in amount than his purchases of clothing, supplies, etc. Thus he, like our goodly country, is thrifty. I rejoice that it is so.

I hope this explains my logic. I regret that I did not make my meaning plain to all before. I thought as I commenced reading Mr. Doolittle's criticism that he was going to say: Why rejoice, for our thrift means unthrift for our neighbors across the water? I do regret that. The entire world looks jealously at our commercial progress. They are alarmed at our late increased thrift. They watch us with increasing anxiety and rapidly increasing prosperity with almost consternation. That should make us no less energetic, or frugal. It should make them hasten to study our methods, and to adopt our practice.

QUESTIONS AND SUGGESTIONS.

Mr. Doolittle's kindly paragraph causes me to urge others to ask questions and make suggestions as to these "Home Circle" papers. I wish to make them helpful to all the readers of the "Old Reliable." One reader kindly urged me to read Henry George's "Progress and Poverty." This friend actually sent me the book. I am studying it carefully, and when it is digested I shall bring it into "The Home Circle." It has valuable suggestions.

Another asks: How shall we contribute? Send me valuable recipes, hints as to living and economies, gems cut from newspapers, any and every thing that will help to make our homes more bright and happy. Send to me thus: A. J. Cook, Claremont, Los Angeles Co., California.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee-Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.
$15,000 in Cash to be Given Away

The Press Publishing Association will give $15,000 in 1,000 Cash Prizes to those making the nearest estimates on the combined Official Vote of Ohio, Massachusetts and Iowa, cast for Governor on the 5th day of November, 1901.

Estimate the total vote in these three States combined for Governor and send your estimate and subscription to the American Bee Journal, and you will receive a certificate, which will entitle you to participate in the distribution of the $15,000 to be awarded by the Press Publishing Association, of Detroit, Mich., to those making the nearest estimates of the Official Vote for Governor in the States of Ohio, Massachusetts and Iowa, to be determined by the Election held on the 5th day of November, 1901.

We have made arrangements with the Press Publishing Association, of Detroit, Mich., to enable our subscribers to participate in the distribution of these magnificent prizes, amounting to $15,000.

Our Offer: Until further notice, everyone who sends us a sufficient amount to pay his or her subscription to the American Bee Journal to the end of this year (1901) will receive the subscription is in arrears at least since Jan. 1, 1901; or to any one sending us $1 for a year in advance of next Jan. 1, 1902, will receive a certificate which will entitle him or her to participate in the distribution of the Prizes. No advance is made in the price of our paper; you get the certificate absolutely free.

YOUR ESTIMATE.—When you send in your subscription you also send your estimate. Be careful to write your name, address and estimate as plainly as possible. As soon as we receive your subscription we will send you a certificate of the Press Publishing Association, of Detroit, Mich., containing your estimate, which will entitle you any prize you estimate may entitle you to claim. We will file a duplicate certificate with the Press Publishing Association. Every subscriber may make many estimates, and will receive as many certificates, as he sends dollars on subscription to the American Bee Journal.

Valuable Information. To aid subscribers in forming their estimate, we furnish the following data:

<table>
<thead>
<tr>

GEORGE W. YORK & CO., 144 & 146 Erie Street, Chicago, III.
GOOD HONEY-FLUCTUATED.
We have just had a couple of good rains, and it looks as if we would have a good, old-fashioned flow of white clover honey. We had a spell of wet weather anything for nearly two months, and I had about given up hopes of a clover crop. A. N. Draper.
Madison Co., Ill., June 7.

DROUTH WILL CUT THE CROP.
Our bees have been storing honey nicely for about two weeks, but the protracted drought will cut our honey crop short, as the white and black clovers are dry ing up or dying, and there is but little sweet clover growing near.
DAVID SHARP.

BEES DID NOT WEAR WELL.
The bees came through the winter very weak indeed, but have built up much better than I expected, so I can hope to get something, at least.
MATTHEW CUMBER.
Grant Co., Wis., June 6.

KEEPING DOWN INCREASE.
I see a good chance for Dr. C. C. Miller to get into a dispute in regard to an answer to a question on page 5 of the American Bee Journal, which reads: "If your object is to keep down increase, perhaps this plan might suit you better. WHEN THE peeps are a little older, kill the old queen and return the swarm. A week later cut out all the queen-cells but one, and the work is done. There will be no more swarming for that colony until another year." That may be so in some locations, but it will not work everywhere. I have had swarms many times after having hived first swarms by themselves and cutting out every queen-cell but one 7 days after the swarm issue. And I have then had swarms from the same colony again in from 6 to 8 weeks. I also have virgin swarms from almost every prime swarm.
C. H. HARLAN.
Kanahêe Co., Minn., May 27.

GOOD Outlook FOR A Honey-CROP.
My winter and spring losses have been very heavy and it has been cold with much cloudy, rainy weather (it is raining today), and the wind seems to have blown from the northeast. But the honey outlook is fine: clover is very plentiful as none of it was winter-killed, and burdock seems to be setting full. The biggest drawback with me is the bees, but they seem to be building up fast now, and may be in good condition for the coming season. I visited R. L. Taylor's apiary, May 24, and his 200 colonies are in excellent condition, most of them ready for the supers, with the clover flow two weeks ahead. Hewintered his bees in the cellar, and I wintered mine outdoors.
E. B. TYRRELL.

LONG-TONGUED BEES.
From a southern standpoint I read with some satisfaction G. M. Doolittle's article on page 296, and Dr. Williger's reply on page 298. I feel quite sure that Mr. Doolittle is very willing that the people of the red-clover belt get good red-clover honey, and also sure that he meant to cast no reflections on the honesty of the people at Medina. I suppose the opinion that these articles will do good. While no sensible man will doubt the advisability of having long-tongued queens in the phone boxes and other places where no benefit whatever would be derived from them. In my own locality (southern Georgia) bees with a 25-300 reach would store
no more honey than our shorter-tongued bees, or their pollenizations, of course, are the same. Although Root closes his advertisement with an "X. B.," saying that the rank and file of beginners have no use for such queens, still they will buy them, and it was this class of bee-keepers that Mr. Doolittle was directing his appeal to.

If some enterprising queen-breeders will get up a non-swarming strain, a greater benefit will be conferred upon the bee-keeping fraternity than tongue-race. By this improvement all of us, from the red clover feeder to the honey-bucket man, and from buckwheat to sage of the West, will jump for joy.

Harrah for long-tongued queens, for Dr. Miller's claim as far as bees go and for bees that don't swarm, for "we ain't!"

Dodge Co. Ga.
F. M. Creighton.

Best Honey-Flow in Years.

Bees are blooming white on clover, and the honey-flow is the best we have had in years. White clover is literally taking the country, for which I am sorry (1).

We are in sad need of foul-brood legislation in this part of the State.

W. T. Stephenson.

At Work on Raspberry and Clovers.

Bees are working very busily on raspberry, white clover and red clover, both clovers being in bloom now. The prospect for basswoods is not as good as in former years, but the calves are coming up nicely. L. G. Blake.

Grant Co., Wis., June 3.

Bee-Keepers' Supplies.

Just received a consignment of the finest up-to-date HIVES and SECTIONS we’ve had. They are M. to none. Order from Beekeepers’ Supplies on hand. Bees and Queens. Catalog free.

$13.00 to Buffalo and Return, $7.00
via Nickel Plate Road from Chicago, for the Pan-American Exposition. Tickets on sale daily, good leaving Buffalo up to midnight of tenth day from and including date of sale. Also tickets on sale daily Chicago to Buffalo and return at $16.00 for the round trip, with 15-day limit, including date of sale, $21.00 Chicago to Buffalo and return good for 15 days.

On all through tickets to points east of Buffalo, privilege of stop-over at Buffalo for 10 days may be granted by the joint Agent and payment of fee of $1.00.

Write John Y. Calahan, General Agent, 11 Adams St., Chicago, for full particulars and folders showing time of trains, etc.

also on inbreeding; for even now some queen-breeders have largely omitted the drones, and where could, and perhaps do, practice selective inbreeding; and in the near future it is probable many other beekeepers will be tempted, whereby the drones will be absolutely controlled.

The experience of the best authorities is that inbreeding is not, in itself, of any detriment whatever. The instances of vigorous animals which have been inbred for many generations are too numerous for the popular idea to be altogether true, for this reason: If the same parents are used, the offspring will have those tendencies doubled. Of course, this is more liable to happen with related or outlying colonies than with those not related. Hence, if any of those common tendencies are bad, they will be approxi-mately twice as bad when the parents are selected by inbreeding. It should be remembered, also, that there are various degrees of inbreeding. To make perfect inbreeding is profitless as it has only half the effect, for good or evil, of mating mother and sister. At present, on the whole, it may be better to avoid stock in bees likely to be inbred, but as soon as queens will be mated in confinement, the case will be altered.

Best Averages from New Colonies.

A Stray Straw in Gleanings in Bee-Culture.

Sometimes it is said that a beginner gets a year's experience and that is all because his first enthusiasm is gone. I believe that's a libel on many of the veterans. A bee-keeper may ride his hobby so hard as to kill it, but they don't all do it. Just 40 years ago I took the bee-fever, and the temperature is just as lively now as it was then. What forward to some things I want to do with bees next summer with just as keen a relish as I had 40 years ago. The extra results secured by a beginner are largely to be credited to the fact that he has a small number of colonies, and so the bees have a better chance. The last sentence explains it in the "A B C" book. The statement is made to the effect that the average yield per colony will be much larger in a small apiary, remote from any other yard of bees, than in larger apiaries—Editor.

Wax-Worms in Pure Wax.

It has generally been considered that pure wax, as in foundation, is in no danger of being troubled by the wax-moth, at least some pollen being necessary to support the larva. J. L. Doolittle reports in the Progressive Bee-Keeper that he found the wax-worms in foundation that had been kept a warm place near the roof.

Sweet Clover Not a Weed.

The following question and answer appeared in the Wisconsin Farmer:

Mr. Editor:—Will you please tell me all you know about the aptness of clover to be grown, whether it is good as a fertilizer or pasture, or whether it is good for nothing. Some tell me it is good as a weed, but a weed is always a weed, and a weed is always as red as clover.

A few clover (Melilotus alba) is a legume, as are other clovers, and because of this fact exerts a similar effect in the renovation activities of the North, generally it is regarded as a weed. Some States have reduced its growth against certain crops. The clover should be destroyed, along with the Canada and Russian thistles. A number of one or two experiment stations have commented on it, as a forage-plant and as a source of frit, it very early becomes woody, and loses whatever value it has as a forage-plant. It has a peculiar taste of its own to which cattle have become
Basswood and Alfalfa Honey

in 60-pound tin cans, f.o.b. Chicago—two cans in a box—at these prices: 9 cents a pound for one box of two cans; two boxes (4 cans) or more at one time, 8½ cents a pound.

We have only a limited quantity of the Basswood honey. Sample of either kind, postpaid, 10 cents. Address, GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

26 cents Cash paid for Beeswax.

This is a good time to send in your Beeswax. We are paying 26 cents a pound—Cash—for best yellow Basswood Beeswax. Low, upon its receipt, or 28 cents in trade. Impure wax not taken at any price. Address as follows, very plainly, GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

Marshfield Manufacturing Company.

Our Specialty is making Sections, and they are the best in the market. Wisconsin BASSWOOD is the right kind for them. We have a full line of Bee-Supplies. Write for free illustrated catalog and price-list.

Red Clover Queens

One Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with $2; or, one Tested Queen free as a premium for sending us FOUR new subscribers with $4.00).

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

All queens guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

Cash Prices of these five queens will be as follows: Untested, $1.00 each; Tested, $2.00 each. Send all orders to GEORGE W. YORK & CO., 144 & 146 Erie St., CHICAGO, ILL.

Feeding in the Open Air.

This is objected to because colonies that need least get most, and because neighbors' bees can not be excluded. It has the advantage that it seems a little more like a natural, harvest than feeding in the hive. M. A. Gill says in the Rocky Mountain Bee Journal:

I hardly dare advise beginners to feed in the open air, but practice that plan myself, I feed in troughs filled with alfalfa stems. From one-half to a pound of honey or syrup made as thin as raw nectar. After feeding in the open air then put them in the hive for a couple of days. If I have any broods filled with honey, I uncap them and hang not more than three in an empty hive, equally spaced apart, and let the bees have it. If properly done, there will be no trouble from robbing. I had as soon feed 100 colonies in the open air as 100 pigs, provided my neighbors do not have too many bees.

The Lowest Temperature for Comb-Building.

S. E. Miller reports in the Progressive Bee-Keeper that he had comb built in March when the outside temperature varied from 18 to 72 degrees, the average being about 45 degrees. He asks what is the lowest temperature at which comb-building can be carried on, and answers from three different experimenters.

J. W. Rous frankly says he does not know, but thinks it can hardly be below 30 degrees. G. M. Doolittle says that bees can build comb in zero weather. Dr. Miller goes still lower, and practically says that no colony of bees has ever lived through a temperature so low that it would not admit of comb-building. Mr. Doolittle says the heat inside the cluster necessary for comb-building and brood-rearing is from 90 to 98 degrees, and Dr. Miller explains how it is that the colder the weather the warmer it is in the center of the cluster. His answer is as follows:

If you mean at what temperature of the brood-nest bees can build comb, it may be replied that it is somewhere in the nineties, probably. From your accompanying remarks, however, it seems that you mean the temperature of the atmosphere surrounding the hive. That's another thing, and the temperature doesn't depend so much upon the strength of the colony.

If a single bee is exposed to a freezing temperature, it will be a dead bee in a short time. If it would not be able to call a dead bee, for it can be revived if brought into a warm place if it has not been frozen too long. If there be a cluster of bees, the bee in the center of the cluster will not succumb to the cold as soon as a single bee, but it will succumb. If there be 50,000 bees in the cluster, with plenty of stores within easy reach, a freezing temperature will not affect them unfavorably at all. And a much smaller cluster
A Home in Colorado FOR SALE

I have a fine Fruit-Ranch of 14 acres here at Fruitia, all set to fine fruit, principally winter apples, with plenty of small fruits, peaches, pears, plums, cherries, apricots, prunes, and about 700 grapes; 100 colonies of bees, most Italian, and about 100 fine Belgian hares that I will sell with the place. The orchard is in fine bearing, being about 10 years old, and is clean and free from weeds. The house is a good 2-room one, nearly new, with bath and water; a good new barn for two horses and two cows; good brick hen-house and two good cellars, good loan and shade. I have a paid-in water right, and a well, and a good abundant supply of water at all times for irrigation. I am desirous of making a change in my occupation, and would sell the place for a bargain. With the proper party the yield from the place this year will be about $2,000. It joins up within 20 rods on the south side of Fruitia, where one has all of the best high schools in the State, employing 7 teachers. It is only 3/4 of a mile to the depot, churches, school and post-office, and has telephonic connections with all parts of the State. This is a good, healthy climate, and good property.

Address for terms and further particulars, W. C. CARNAHAN.
Box 64, Fruita, COLO.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, June 7.—Not any new comb honey has come to this market up to date hereof, but there are as long as many as we can get a month or more in. A little good white comb still on sale, which easily brings $1.40 per cwt. or more, against other kinds. Extracted very dull, practically no sales made. Beeswax in fair demand at 210c. per lb.

R. A. BURNETT & Co.

DETROIT, June 8.—Strawberries are taking the attention, and very few sales of honey are made, but prices seem quite reasonable and good lots. Beeswax in fair demand at 210c. per lb. M. H. HUNT & Son.

CINCINNATI, May 17.—No comb honey, also stock of it well exhausted. Extracted very dull; sales are more or less forced; lower prices from 19c. to 1 cent per lb. C. W. WEBB.

BOSTON, May 21.—Our market continues dull on honey with very light stocks on hand. Normal prices are as follows: Fanny 1-pound cartons, 1st, 14c.; 2nd, 13c.; No. 2, 12c. Extracted from 6c. to 10c.

BLAIR, SCOTT & LEE.

OWAM, May 1.—Comb honey, extra white, 24c.; cases, per case, $6.75. J. C. P. ABOTT.

LEARN TO SING AT HOME by my thorough method. Teaching plans, complete course I guarantee to train and enable you to sing well and easily, without expense. The best musical knowledge possible. Most desirable for girls, for young women. Highest Endorsements. Beneficial for voice and health. Write for free illustrated book.

AND so to-day I'm seven times ten,
And hence 'tis said I live on "borrowed time."

Well, what do I have that was not lent
By Him who made me what I am!

My life, and all that goes to make it up—
From deepest joy to sorrow's cup—
These all are borrowed from His gracious store.
But some day He will give me better things—
Yes, the best He has, and they shall all be mine
Throughout unending ages.
You say I'm on the "shady" side of life.
Not so, my friends; the shadows are behind,
Along with all earth's troubles.
I see ahead the Sun of Righteousness,
Whose beams already light my path.
And render it more pleasant to my tread
Than aught that this world has to give.
But even if the shadows do at times
Fall o'er my pathway, dark and deep,
I'll pause a moment, wipe my brow,
And then press on, not to the light,
But in it and toward it.
The best of life is still ahead.
And, I am sure, it always will be so:
For morrow's sun has something for the child of God
Far better than the things to-day has brought;
So don't console with me on ripening age.
For that is but another name for labor done,
And an advance toward that gladsome day
When we shall gather up our jewels.

Dr. C. C. Miller

June 10, 1831.

June 10, 1901.

W. P. Root.
Dr. C. C. Miller, of course, is different from some ladies in the usual number of particulars, and also has another distinguishing dissimilarity. He still has birthdays. He had one the 6th of this month. He is now 20 years old—or, we should say, 70 years young, for he’s on the sunny side of 70 now. At least he would tell you that if you were to ask him on which side he is.

Dr. W. P. Root, known as “Stenog’Mn” in Gleanings in Bee-Culture, has sent us the poetic statement on the first page of this number. He has expressed for Dr. Miller quite clearly just what the Doctor could say, though perhaps in a different manner.

Dr. Miller is the most prolific writer on the subject of bee-keeping to-day. He has been in the bee-business over 40 years. and he doesn’t claim to know it all yet. To many a question relating to bees and bee-keeping he is compelled to offer the laconic reply, “I don’t know.” And yet his fund of actual information, gained from his years of practical experience in the apiary, is something remarkable.

Further, we were going to say that Dr. Miller is the best loved bee-keeper in America, but we won’t say it, for the Doctor wouldn’t thank us for it. He is the quintessence of modesty, and so we won’t say too much at this time. And yet to say the good and well-deserved thing now is much better than to wait and place them in bouquets upon the casket that some day will contain all that is mortal of him.

We can truly speak not only from our own heart, but for many others, who appreciate Dr. Miller, his life and work, and pray that he may be spared to us all yet many years ere he is called “up higher.”

Mr. R. Wilkin, one of the oldest and most prominent bee-keepers of California, died at Newhall, Calif., May 30, 1901. He was father-in-law of J. F. McIntyre, another leading bee-keeper of the same State. We hope soon to be able to present a more extended sketch of Mr. Wilkin in these columns.

Mr. John W. Backman’s East Side apiary is shown on page 40 this week. It is located in Fairfax Co., Va., and all but two of the hives are double-walled. The地点的前缀 faces east, and is beautifully situated. The little girl at the hive is his youngest daughter, and the lady to the left is Miss Castell, his helper in the apiary. Mr. Backman says she can find a queen as quickly as the most experienced apiarist, and is a good bee-keeper, besides being a fine scenerist. The two bees in the background, carrying the colony of bees, are his two sons who are running the farm. The lady to the right is another daughter, and the man with the smoker is Mr. R. himself.

He thinks his hives are the finest in the United States, as they are a perfect piece of cabinet workmanship, being thoroughly made, then painted with white lead, the masts being all sunk, then putted, then sand-papered, and then painted with the white lead. They are on stands 11 inches from the ground, nor would he have them on tight stands, but wants them so that the cats and chickens can get under them, and so that there will be free circulation underneath. In this way the bees keep dry, the bees are healthy, and there are no ants or mice to bother.

The day that the picture was taken there was a fierce fire raging just at the left of his place, and his wife and youngest son were badly frightened, and were watching the fire, so that is the reason they do not appear in the picture. Two of his houses were within 50 feet of the fire, but no damage was done to his property.

Mr. J. H. Hodgkins, of Winnebago Co., Ill., writes us that he thinks he is about the oldest subscriber to the American Bee Journal, as he has taken it continuously ever since its first editor, Samuel Wagner, began to publish it in 1881. He has never missed receiving one number in all those years, and he has preserved nearly every copy.

We suppose there are not very many of our subscribers who have such a record as Mr. Hodgkins can show.

**UNTESTED Italian Queens Free**

BY RETURN MAIL.

For sending us One New Subscriber for one year, to the American Bee Journal, with $1.00, we will send, by return mail, a fine Untested Italian Queen free as a premium. This offer is made only to our present regular subscribers.

We will mail one of the above queens alone for 75 cents; or 3 for $2.10.

Please do not conflict the above offer with the one on another page which refers to Red Clover Queens. For sending us two new subscribers, and $2.00, we will mail free as a premium an Untested Red Clover Italian Queen.

**GEORGE W. YORK & CO.**

144 & 146 Erie St., CHICAGO, ILL.
Questions for Discussion at the Buffalo convention may be sent in at any time from now till Sept. 10, to Secretary A. B. Mason, Station B, Toledo, Ohio. For more than one reason it will be better to mail your questions in advance than to wait until you are present in person at the great meeting of the National Bee-Keepers' Association. You may forget a question if you wait, and if several offer the same question the duplicates will be thrown out in advance. This feature of the convention is a very commendable one. The live discussions in a convention are what give it its greatest value.

Repression of Drones.—Perhaps no one has kept hammering away on this subject more than G. M. Doolittle, and no one has gotten it down to more practical shape. He discusses the matter in the American Bee-Keeper, and although there may be little he has not already said, and therefore is in this journal, it is worth repeating for the sake of some of the beginners, and more especially for some who are not beginners, but have not given the matter sufficient heed. He says:

"I have yet to see the hive containing a populous colony, one strong enough to send out a prime swarm during June and July, that had not a few cells of drone-comb in it; and I do not believe that these few cells can be kept out, for worker-comb will be cut down and drone comb made. If, however, these cells can not be gotten otherwise. From my experience in the past, I would say that it is not practicable to keep drone-comb out of any hive, but rather have just one frame in each and every hive, having from 10 to 30 square feet of drone-comb, as I am sure that it is desired that no drones shall fly, and decapitate them, thus making a sure thing of the matter, and fully satisfying the bees. In this way you will not have a few drone-cells scattered all through the hive, nor will you have to use a drone-comb at the entrance of such hives to catch undesirable drones, the same making quite a cost and much work for the bee-keeper in putting them on and emptying the same; besides a general bother and disgust to the bees when first put on, and at times of the flight of drones and young bees.

If this comb with drone-cells is placed near the outside of the hive and the drone-comb is near the top-bar of the frame, you will not have to decapitate the drones more than two or three times during the season, for the queen will be slow in depositing eggs in it; and when honey comes in so the bees begin to prepare for winter, they will fill it with honey, thus keeping the queen from depositing any more eggs in it that season.

If, in addition to the above, the top-bar to the drone-comb is covered with a piece of drone comb, is painted white or red, you will know just where this comb is without taxing your memory; this will fill it with honey, thus keeping the queen from depositing any more eggs in it that season.

Is It Profitable to Use Foundation?—S. E. Miller discusses the question in the Progressive Bee-keeper, and while not questioning its use in sections, he does question the profit of using it in the work of drone-hive filling. He argues that yes, an S-frame hive filled with medium-brood foundation, freight and all, will cost 55 cents or more, and thinks, in many cases the 55 cents is never gotten back. In reply to the claim for straight combs with no drone-cells, he says:

"I have in my apiary as nice all-worker combs built on starters as any one can show built on full sheets. I have others that contain partly drone-comb, and some nearly all drone, but these are by no means useless as I use them in the upper story for extracting from, or, if I wish to, I can cut out the drone-comb, if it works well, as Mr. Doolittle does, but I must confess that I have never done this as thoroughly as I should have done.

Mr. Miller argues that he can ent the drone-comb and replace it, and then with charming frankness confesses he has not thorougly done this. Ah, there's the rub! Bee-keepers can cut it out, but do they? Those who have had much practice in the job know that it is some time and trouble, and it is easier and safer to prevent than to cure. The probability is that if Mr. Miller would count what he has done, he would admit that his 55 cents came back with interest.

Suppose, however, that we take the ease of a man who promptly cuts out all drone-comb, or removes it to the extracting-chamber. Before that drone-comb is cut out it must be built, and that building costs wax and labor for the bees, to say nothing about the time of the bee-keeper in repairing. But the waste of the drone-comb is not all. As fast as it is built it will be more or less filled with drone-egg—generally more—and that brood is a waste. Unless the man is very careful and prompt, a good deal of the brood will arrive at the sealing stage before it is cut out, and that will be much the same as throwing away a comb of honey of the same size.

The argument that drone-comb can be put in the extracting-chamber may have some weight where there is an extracting-chamber in the case, but cannot in comb-honey production.

After all this is said in favor of foundation in the brood-nest, it should be added that there are good authorities who think it economical to use a swarm nothing but starters for the first half of the frames. If hived on these there will be little, possibly no drones built, the building of drone-comb commencing after the first half of the hive is filled. To prevent the building of drone-comb in this second half, full sheets of foundation are given after the first half are filled.
Another feature of the Fair, and one not to be overlooked, is the premium list. I find by referring to the premium list for 1900 that the sum of $280 was divided into 79 premiums, comprises the list which is composed of 235 lots, beginning with the "most attractive and finest display of comb honey," and ending with the "grand sweepstakes," which requires the most attractive exhibition in this department, all things considered.

In order to understand this matter properly it is necessary to compare the Minnesota list with one or two others, whose shows, by the way, do not come up to that of Minnesota by any means, for instance:

<table>
<thead>
<tr>
<th>Minnesota</th>
<th>Illinois</th>
<th>Wisconsin</th>
</tr>
</thead>
<tbody>
<tr>
<td>Finest display of Comb Honey $125 5-3-2-1-</td>
<td>820 15-3-5-</td>
<td>48 8-4-12</td>
</tr>
<tr>
<td>Beeswax 100 3-2-1-</td>
<td>90 15-10-15</td>
<td>40 2-1-3</td>
</tr>
<tr>
<td>Granulated Honey 5-3-1-9</td>
<td>70 15-10-15</td>
<td>40 2-1-3</td>
</tr>
<tr>
<td>Honey-Vinegar 6-2-1-</td>
<td>40 8-4-12</td>
<td></td>
</tr>
<tr>
<td>Extracting-Frames 5-3-1-9</td>
<td>50 2-1-3</td>
<td></td>
</tr>
<tr>
<td>Nucleus of Yellow Bees 3-2-1-6</td>
<td>40 3-2-9</td>
<td></td>
</tr>
<tr>
<td>Carniolan Bees ...</td>
<td>3-2-9 8-4-12</td>
<td></td>
</tr>
<tr>
<td>Total for bees ...</td>
<td>40 3-2-9 8-4-12</td>
<td></td>
</tr>
</tbody>
</table>

It will be seen from the foregoing that in some particulars our premiums are considerably behind those of Illinois, while in some cases they far exceed Illinois' offers. For instance, Minnesota pays a total of $121, divided into six premiums, for bees, while Illinois pays a total of $27, and Wisconsin a total of $24, divided into four premiums. It is to this part of the premium list that I would like to call special attention. It has been my opinion, and I think I can always get just about what he is willing to pay for, and this holds as good in exhibiting bees as in other walks of life. I will venture the assertion that there is not a bee-keeper present that would care to take a choice queen with a modest number of her bees, and shut them up in an observatory hive for a week in an overheated room like that at the State Fair, for a premium averaging from $5 to nothing. It simply will not do, even in this day of the so-called "grand sweepstakes," of the Fair of 1900, and I consider the remark of the judges that it was the poorest lot of bees they had ever seen, most perfectly justifiable. Were the same policy pursued with other kinds of stock the result would undoubtedly be the same in a very short time.

I hope that anything said in this paper will not be regarded as a complaint against the premium list or any one connected with the management of the Fair, for it is not so intended. In the main, the premiums are liberal, that is, while only a few bee-keepers make exhibits, but suppose 50 should decide to make exhibits, then there would not be enough to pay the expenses of half of them. Should we ever be blessed again with a good honey-crop and a pushing assistant superintendent, it would probably be sate, and every one might be secured. While our present assistant superintendent holds office I can assure you that there will be but very few bee-keepers in the State that will not have an invitation to attend the State Fair.

The State Fair has been quite a success, its finances are steadily increasing, and it seems to me that the time has come for this Association to take some steps to secure more money for the premium list. It is not my intention to say just what should or should not be done in that line. My main object in writing this paper is to outline a few of the more important features of the premium list where they might be amended, in order to start discussion: for I consider that unless the reading of a paper does that it fails entirely in its purpose, for "in a multitude of counselors there is safety."

WM. RUSSELL

Following this paper was one by Dr. E. K. Jaques on "Bee-Keeping for Pleasure."

The election of officers for the ensuing year resulted as follows:

President, WM. Russell; first vice-president, G. A. Forrgeron; second vice-president, G. H. Pond; third vice-president, Dr. Mary McCoy; secretary, Dr. L. D. Leonard, Syndicate Block, Minneapolis; and treasurer, L. E. Day. Executive committee, H. G. Acklin, WM. van der Molen, W. Acklin, L. D. Leonard, Sec.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.
Contributed Articles.

Thick vs. Thin Brood-Frame Top-Bars.

By S. T. Pettit.

I WOULD like to reply to Dr. Miller and Editor Root, who seem to be not a little excited over my article on top-bars in Gleanings for March 19, and want to say that I endorse all in regard to wide and thin top-bars; but I believe combs-are more plentiful with the use of top-bars 3/4-inch thick than with 3/8-inch thick. Can it be that the length of the Langstroth top-bar does not have any effect on this thickness? With due respect to the editor, I firmly believe he is mistaken in that. My experience with 3/4-inch top-bars covers a period of 15 or 16 years, and it is altogether different from his. I have made many tests with the different kinds, so it is not theory but long experience from which I speak.

On page 380, Dr. Miller says, "His strong point is that, by having 3/4-inch more depth, the space of 1600 to 2000 cells is lost." Yes, that is my strong point, which I will take farther notice of later.

I did not make the mistake of reckoning that the same number of bees were occupied brooding those sticks as would be occupied in brooding 3/8-inch thick comb. I neither thought it, nor said it, but this is what I did say, "The thick top-bar is a mistake. Our best consideration." I think most bee-keepers will agree that 1600 to 2000 cells in a hive are of more value than useless lumber, adding weight and unnecessary expense. I hope after due consideration the Doctor will agree with this also.

Then the Doctor proceeds to use about half a column, and proves nothing, except that he "don't know" what he is talking about—it's all wasted energy. Farther on he says, "So if the prevention of burr-combs by detector-combs does not, in fact, save a cell, then the combs are all a delusion (which I do not believe)!"—well, I suppose I can show the reason why he does not believe it. He did not make personal, practical experiments for himself and for the benefit of the public for whom he writes; but well, perhaps I can do no better than to give the article of Editor Root, as follows:

"Dr. Miller was greatly struck with the idea, and after some extended correspondence with the Doctor we decided that we would launch forth, for the ensuing year, the new top-bar.

Then later he said that he and Dr. Miller had evolved the new top-bar, by revolving around each other by the coat-tail—a clear case of conviction and prejudice not founded upon personal, practical experience, hence the Doctor's complainant "which I do not believe."

I quote from a letter sent me from the U. S. A., dated April 4, 1901: "I have read with much interest your article in Gleanings for March 15, and want to say that I endorse all in regard to wide and thin top-bars; but I believe combs-are 3/4-inch wide. For a number of years I have been using a top-bar 3/4-inch thick, and 1 1/2-inch wide, and not a burr-comb on a single frame in 8 years' use." I may add that a few days ago Mr. Cruikshank, who takes Gleanings, and lives near me, came to see me and in alluding to this discussion said: "I use 3/8-inch thick top-bars, and have no bother with burr or brace combs."

But Doctor Miller says, "I still want the 3/8 top-bars for the sake of having the sections so far from the brood-combs that the bees will not find it convenient to carry up a lot of black wax to spoil the snow-white sections." This statement reveals the fact that the Doctor has not yet learned all the valuable uses to which the queen-bar, or perforated metal queen-excluder may be put. My practice is to get the sections just as close to the brood as I can, preserving all the necessary bee-spaces. To this end I want thin top-bars. Then, to prevent the bees from moving up dark wax, and to bar the drones with their filthy habits, and the queen from the sections, and to restrain pollen, I use a queen-bar, or, if you please, an all-metal perforated-metal queen-excluder. When the drone has a burr, it has a cross-pieces. This arrangement gives the same distance between the top-bars and sections as he wants, with all the advantages enumerated. But I would bring the sections closer down if I could and not dispense with that editor.

Cross Bees at Swarmingle-Time, Etc.

By W. M. Whitney.

SOME one asks why bees are sometimes cross when swarming. Tell him to examine the hive they came from, and if he finds little or no honey, the question is easily answered. Who wouldn't be cross, crowded out of home with the whole family in a starving condition? Or, possibly the swarm has been clustered a long time. Pull one of the crossest ones in two, and see how little honey it has in the honey-comb. If they have plenty of honey, they are gentle as kittens—wouldn't sting if they could, and couldn't if they would.

Introducing Queens.

The communication on page 311, entitled, "Introducing a Queen-Bee," etc., is really amusing. The gist of the whole article seems to be a priori attempt to show that the honey-bee is actuated by pure, unadulterated motives. Now, it occurs to me, that taking the effects indicated in the communication as causes, and reasoning a priori, it would not be a difficult matter to show that the honey-bee is prompted by the highest type of love and patriotism. A community of individuals, in which individual rights and privileges must be held secondary and subject to the well-being of the body collectively. But enlightened and Christian people, places of comfort are provided for the unfortunate and infirm; but, the time was when such persons—whether their condition was the result of heredity, accident, or age—were disposed of in the most convenient manner possible, as the occasion for the good we do. The people occasionally hear the thought expressed that such might still be a good practice.

The community of bees, either in instinct—or if any one can show what this implies—it is by some other power, seem to know when any member among them has ceased to be of use to the body as a whole, and take the only possible means to perpetuate the existence of the colony. Why, how long do you suppose a colony of drones, caged, etc., to provide an all-metal—when the hive, nurses to care for the drones and queen, the dear old mother-queens, and the ever faithful, but weak and worn-out workers? Does not the existence of an existence—How persistently the little heroines defend their heart-stone against all intruders, even to the sacrifice of life itself. How carefully they
Circulation and Respiration in Insects.

By PROF. A. J. COOK.

ESPIRATION and circulation, or the securing of oxygen and elimination of waste, and the conveying of elements from one part of the body to another, are exceedingly important functions of highest importance in the higher animals —so important that we denominate the cessation of these functions as death. A chicken in Michigan lived for weeks with its head cut off. That part of the brain—the medulla oblongata—which is the centre of breathing, remained intact, and so the chicken continued to breathe, and the heart ceased not to beat, and so the chicken lived. Of course, it could do no thinking, nor could it walk; but so long as breathing and the circulation of the blood continued, we said the chicken lived.

In insects, and in so many bees, respiration looses none of its importance; but because of its peculiar character, the circulation of the blood becomes much less complicated. Insects may say that the respiratory system is inversely proportional in its complication, to the circulatory apparatus.

In us, as with nearly all vertebrate animals, breathing is specialized, and restricted to narrow limits. The lungs are the principal organs in breathing. They are their seat of action. These limitations make a very complete circulatory apparatus very necessary, and so we have the great force-pump—the heart—the conductors leading from it, the arteries, which convey the life-giving fluid to the tissues; and the veins, the great conduits, that return the blood again to the heart. The oxygen, which is really the most important of all substances, is only received in any considerable quantities by the lungs, and skin respires in a small way, and so we get a modicum of oxygen through skin respiration the blood then must have two circuits—the one to the lungs to get this vitalizing oxy-

igen, the other to the body to give this same oxygen to the tissues. Equally important is circulation, in bearing the waste from the tissues, and equally important are the processes in separating this waste—the ashes of work, if we may so speak—from the blood. All the blood which comes into the lungs is a single tube—trachea—and enters this either from mouth or nose through a single aperture—the glottis.

When we come to insects, we find a very different arrangement. The bee and all insects must have the oxygen, and if very active, as are bees and all other insects of their order, they must have a large amount of this vitalizing element, the most important food-product. The insect’s breathing-organ is very different from ours. It is also by means of the spiracles which are breathing-tubes. The breathing-tubes, or tracheae, are in the thorax, and the branches of them are the tubes we find them. Thus the life-giving oxygen goes everywhere in the body, and there is no need of a complex system to circulate it.

These tracheae are curious in their make-up. They are made of spiral threads, lined with an epithelial or cellular membrane, as are our own bronchial-tubes. Thus the ultimate structure of the insect lungs is not essentially different from that in higher animals. In both cases we have an intricate and extensive ramification of tubes, lined with a central spiral thread. In the insect respiratory system, the tubes in the insect respiratory system, is in appearance and construction, as if we should wind a fine wire closely about a lead-pencil, and then remove the pencil without disturbing the wire. From this it follows then, that the insect’s requirements are met in that air, or rather oxygen, is carried everywhere to the tissues.

The circulatory apparatus, then, need not be very complex or energetic. It has not to carry the all-important oxygen. Thus we may call the blood of a bee, red. Blood is red because of a coloring element called hematoglobin. This is large in amount, which shows its importance. It is emphasized as we know its function, and it is to carry oxygen. In insects there is no need to carry oxygen, as the air goes everywhere.

We understand, then, why insects have no red blood. Were it there, it would be like Othello in the play—its occupation would be gone. The only organ of circulation in insects is in the heart. This is dorsal, and lies close along the middle line of the body. The blood in this vein passes back to the head. This heart action is to keep the blood stirring, so that as active tissues take out the nourishment, no portion may be depleted of nutritive elements. All is constantly being mixed. And so all the blood is kept as rich as any of it. Thus we see how an intricate or elaborate air-system makes unnecessary a complex circulatory apparatus. The machinery in all organic nature is always simple, unless there is call for something intricate.

Scientific Breeding as Applied to Bees.

By ARTHUR C. MILLER.

I N an editorial on page 355, reference was made to an article of mine entitled "Scientific Breeding," and justly so, and the writer, having a task upon hand, was in-breeding with in-and-in-breeding. When writing that article I had in mind in-and-in-breeding as that term is commonly understood, and I sought so to have expressed it. It is commonly understood to mean the promiscuous breeding together of animals closely related, and as the result of this in ignorant or careless hands is generally disastrous, it is supposed to prove that the breeding together of such relations is disastrous per se. On the contrary, it is the chief reliance of the skilled breeder for intensifying desirable tendencies.

The article was not intended to be an essay on thorough breeding, but was intended to do exactly what it has done,
i.e., call attention to the then present status of the subject, a concise interest, comment and study. The breeding of stock in such a way as to develop and establish desirable traits, or, in a word, thorough breeding, is a subject on which many volumes have been written, and to endeavor to give any satisfactory exposition of it in the space available for an article in our bee-papers is impossible. The best we can do is to call attention to the subject, refer those interested to the standard works on it, later discuss salient points, and study it as applied to bees. We shall certainly only ever reach the ideas and laws applied to higher animals, for with bees the drone does not represent two lines of blood, as does the queen, and other factors are also different and will require much study and research.

I believe the breeding of queens is passing into the hands of the amateur bee-keeper. A few years ago the art was restricted and skilled in the art. It is for the best good of all concerned, and Mr. Martin's plan is in this direction. For a time it may cause some personal dis-trust and necessity for readjustment by those who have to drop the business, but bee-keeping will be benefitted thereby. It is only the working out of the natural laws of specialization and the survival of the fittest. Those who kick against it will only show their ignorance of great fundamental truths.

The exact details under which the system will be conducted are properly a subject for debate, and the more full the discussion the more readily will the change be made. The average honey-producer is certainly not in a position to study into the traits of individual colonies, nor when he observes desirable characteristics has he the time or skill to develop them. But if he can turn that queen over to the queen-rearer with a statement of all the observed traits and of the pedigree so far as known, then is she placed where the man with the time and training can observe, and act on his observations. Suppose each of twenty skilled queen-rearers were given a look at the queen-specialist's best queen, would he not then be in a position to, even if not able to control the drones, he could produce queens far beyond anything we now have? The skilled queen-breeder of to-day need not fear this plan, for if he has the power to survive he will introduce his drones as queen-specialist. Rambler's plan is entitled to our serious consideration.

Providence Co., R. I.

No. 7.—Practical Lessons for Beginners in Bee-Culture.

By J. D. Gehring.

(Continued from page 270.)

Now, Mr. Bond, I continued, "if you will please come a little closer I will show you how I take a super off the brood-chamber.

Mr. Bond took two or three rather timid steps away from the apple-tree, against which he was leaning with a worried expression of things, and then halted when he saw me using my old chisel at one end of the super to loosen it from the frames.

"O, come along!" I called, when a side glance showed me his action. These bees are as tame as kittens now. They'll make no sign of a fight while they are full of honey, you know. Don't forget that, Mr. Bond. And, let me remind you, also, don't forget that you are wearing the best kind of a bee-veil, and are at liberty to keep your hands near your head. You can pull the bees by the head, as you wish to do so.

"As I was saying this I had reached the last frame in my prying operation, and, as that frame stuck to the super worse than any of the others, it came loose with a snap and a bang, the usual result—with which all practical bee-men are familiar. In an instant, I heard that special buzz for my smoker, standing near by. A few puffs of smoke, only, were required to drive the out-rushing bees back. My quick movement in reaching for the smoker must have looked to Mr. Bond as the effect of sudden fright, for he uttered a fairly hearty guffaw, and I think he kept the smile from his face when I suggested, "Say, Mr. Gehring, how long will bees stay tame after you've made them gorge themselves on honey? Those in that hive act as if they hadn't had a lick of honey to eat today. Do you know that it is now 4 o'clock, and that it was 2 o'clock when you left them to 'tend to that swarm?"

Mr. Bond was right. But I wasn't quite willing to acknowledge that I had made a mistake by forgetting the polity. I, therefore, attempted no direct reply to his bantering questions, but said:

"I'll show you in a few minutes, Mr. Bond, that these bees will behave all right. I have never had any experience that no harm is being done to them. If you'll come here and take this smoker while I take the super off, it will be a good lesson for you for future use.

Having thus persuaded Mr. Bond, and I continued: "Now, when I lift the super the bees may make another rush. If they do, just blow a few gentle puffs of smoke over the top of the frames—that will send them back. But if they make no rush, nor act 'lightish,' don't use the smoker on them.'"

"Do you mean fear, or emotion I raised the super a short way above the frames, and carefully inspected it. There was a very small swarm, of course took wing, but made no vicious demonstration. Mr. Bond, however, did not know how to interpret the actions of bees, hence he did not waste the opportunity. On the contrary, he just wanted me to do what I thought best, and I would do. Before I had time to turn, after setting the super down, he was pumping the smoker with frantic energy, and sending dense volumes of smoke down between the frames of the open hive.

"Quit that, Mr. Bond!" I cried—not taking time to be polite. "Stop that smoke! Don't you see the bees are not doing any harm? Never use the smoker unless it is absolutely necessary! Remember that, now and always, Mr. Bond. You can't make bees take the effect of the smoker harder to handle, because smoke-treatment like that frightens and irritates them. You can see that for yourself," I concluded, pointing, as I approached the hive, to the bartender, who, though they were pouring forth, in a frantic rush to escape the smoke.

"I beg pardon if I didn't do the right thing at the right time," meekly replied Mr. Bond, as he handed the instrument of possible torture to me. "But, you see, these practical lessons you're giving me are hard on the nerves—my nerves, I mean."

"That surprises me, Mr. Bond," I replied. "I always had a sort of an idea that 'fair-fat-and-fourty' people, like ourself, needn't be bothered with the little things. That was the indirect effect. The indirect effect of it was, or is, that your lesson will have to be postponed for to-day. It is now too late in the day to keep the hive open longer for the purpose of giving a lesson on the subject. Besides, it would not be wise, or even merciful toward the bees, to trouble them further while they are unduly excited. You needn't keep your veil on any longer now, Mr. Bond. There is no danger at all after I get this super back on the hive," I said, as I was replacing the super, and then closed the hive.

"That means, then, that school's out and I'm dismissed. Is that it?"

"Not exactly dismissed, Mr. Bond," I replied; "for I want you to come again as soon as you can, on a bright, warm day. Remember to come as early as seven in the morning, when you do come.

"In the way, Mr. Bond, I lest I forget to ask you: Do you take the American Bee Journal? I name that, in particular, because I read it in preference to any of the other bee-papers, and because I think it's the best in most respects; though others, as far as I am concerned, are good, too.

"We were walking toward the honey-house as I talked. On the way Mr. Bond removed the bee-veil and carried it in his hand until we had reached my work-room, of which he asked to take a seat, but before doing so he handed me the veil, and then said:

"If you had asked me that question about the Bee Journal the first thing this morning, I would have seen no reason for hesitating to tell the truth about it. But after
the experience I have had to-day, and the lesson I've had in practical bee-keeping, I'm ashamed to confess that I have never taken the American Bee Journal as a regular subscriber. The fact is—and perhaps I ought to be ashamed of that, too—I've never before felt, as I now do, that I needed a bee-paper of any kind. My good old father never took any, and he got along very well with his bees—that is, I always thought he did before to-day.

"You have done no worse in that," I replied, "than hundreds of others are doing all the time, without ever feeling a pang of guilt, or showing the least sign of repentance. And most of all, when you've got good and sensible men and women, too, Mr. Bond. The Missouri gentleman who wrote you about was one of that class of bee-keepers. He sneered at the very idea, when I asked him that same question I've just put to you. But you know what he lost by being wise in his own conceit. If you haven't forgotten what I told you about his bee-business transactions with me. Why, Mr. Bond, that man actually laughed at me when I tried to convince him, one day, that bees have eyes and could see as well as men!"

"No, Mr. Bond," I concluded, "it never pays to try to get along successfully in the bee-business, on a large or on a very small scale, without a bee-book to begin with, and a bee-paper to continue on.

(To be continued.)

Questions and Answers.

Conducted by

Dr. C. C. Miller, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—Editor.]

Exchanging Old Colonies With Nuclei.

I had a mind to form nuclei from a colony that swarmed a week ago. Rather than to destroy queen-cells I thought to form nuclei with them. Then to remove other hives and place these nuclei in their places, but a friend told me if I did, the returning bees would be likely to kill the bees and destroy the queen-cells. Would that likely be the result? On going through it to-day I found one queen, but three or four cells, and they all empty, so I could not have carried out my project had I wished. It appears I got that idea from Gleanings in Bee-Culture, but haven’t it to refer to now.

Iowa.

Answer.—Put a nucleus with a young queen in place of a strong colony, and there is danger that the queen may be killed. And you may actually that a queen-cell would be disturbed by the returning bees.

Effect of Too Many Stings—May Have to Abandon Bee-Keeping.

I have been keeping bees three seasons, and had many stings. The spring of 1900 I was troubled with burning and itching, and it lasted about two months. I thought I told you about it, but last March I received quite a lot of stings on the head and face, and now I am troubled terribly with itching, burning, and breaking out over the body as well. The doctors were of the opinion that I was suffering from some kind of poison. I am 65 years old. What is my trouble?

I visited relatives in east Virginia three years ago, who have many bees. I had rhumatism badly, and they assured me if I would get bees, and work with them, and receive stings freely, the formic acid would certainly cure me; and to my hope I do not have any rheumatism now. I have frequently thought if Dr. Miller would caution beginners against too much bee-poise, it would have been for the best.

Let me add that I at first rather encouraged stings. Now I am seeking a remedy to eradicate the poison. I am reasonably sure that my blood is heavily charged with bee-sting acid. I think Prof. Cook doesn’t claim it to be formic acid.

Kentucky.

Answer.—Your case is a very exceptional one, and it is among the possibilities that you may never be able to work with bees without suffering too much inconvenience. No remedy, however, will be needed for the stings received in the spring. It is not supposed that the poison remains in the system, and all you need to do is to avoid stings in the future. It is also possible that in time you may become habituated to the stings so as to be able to continue working with bees. It will certainly be well for the present to take some care not to have too many stings, at least until you find that no serious effects result. If you find no abatement with time, but every sting bringing just as much suffering as ever, then your only course is to give up bee-keeping entirely.

Management for Increase.

As I am trying the Newman plan of increase it hardly suits me, as he says to put the queen-cells on a new stand. I wonder if that is possible with the queen on the print? He says remove the frame on which you find the queen and three other frames of brood, and put into a new hive on the old stand, removing the old hive to a new stand, then put in a queen-cell 24 hours later. Do you think that would depopulate the old colony so there would be danger of the cell getting chilled?

Wisconsin.

Answer.—There might be some danger in the direction you indicate. Do this: Put the queen with half the contents of the hive on a new stand, and a day or two later let the other hives swap places giving each a new stand. In that case, as you put the queen on the new stand, enough bees for safety will remain with her, and by the time you make the exchange some of the bees will have marked the new location so as to return from the field to it, and your part without the queen will have learned their queenlessness by the time the exchange is made, so that there will be no danger of their deserting the brood.

Feed for Weak Colonies—Foul Brood Question.

1. Is there a good substitute for honey with which to feed weak colonies? If so, what?

2. In what way does foul brood manifest itself? There are young bees lying on the outside of some of my hives. They are still white, and do not have their wings formed yet.

Pennsylvania.

Answers.—1. Granulated sugar with water, or a syrup therefrom, is probably the best. In the spring, after bees are flying daily, almost any sweet that bees will take can be used.

2. It is hardly the place to give here all about foul brood. Consult your text-book on bees. But you need not fear foul brood because young bees still white are lying outside the hive. If there are only a few, it may be the work of wax-worms. More likely, especially if there are many of them, the trouble is starvation. In that case, you will find some of the skins carried out with the insides sucked out.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper’s song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at $1.00.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once. If you want a copy of this song.
The Afterthought.

The "Old Reliable" seen through New and Unreliable Gla ses.

BY E. H. HASTY, Sta. B Rural, Toledo, O.

EARLY QUEEN-BEARING IN THE NORTH.

Swarthmore, you're a "clever chic," but all the same, queens in the North are not going to be reared for sale six or eight weeks after the general season. The weather, we have all found this a phenomenally backward spring) is a fearful antagonist to buck against. Why, this spring seeds planted in pots in the window, inside the house, refused to come up. I sowed a lot of winter and spring in a place, when the record is no longer needed, is simple and effective. I use for this purpose the broad side of a section—carry one or several in my pocket—and renew the surface on occasion by shaving it with my pocket-knife. In other words, it is an excellent way of getting things which are eventually to be put down in a book. Quite inconvenient to be running to a book to write as often as a poor money demands. Say, dear reader, don't you need a wooden-pocket-book? There's lots of "money in it." Page 309.

APPLE-BLOSSOM HONEY.

Allen Latham's way (page 310) is all right to get choice bits for home table. Hardly to attempt to modify it as to boom the main harvest. I maintain one-third from apple-nectar and one-third sugar-honey would be still more exquisite than apple-honey pure and simple. Apple-honey inclines to have a little too much flavor. He's right that it is delicious the day it is brought in; but I would hardly agree that it is the only nectar good at once. He must have forgotten the basswood. Probably no nectar whatever is fit to keep if extracted when only one day old.

FEEDING BEES IN A TOPLESS WIRE ENCLOSURE.

If it is really true that all that is needed to feed any colony in the open air is a wire fence around it six feet high (top open to the sky), we certainly ought to know it. Very unique and remarkable for our arsenal. But let's not tell our brothers that it never kicks till we have fire it off several times with our own shoulders against it. You see, Mr. Latham, you said the home bees quickly learned the way out in and in it and in it and I strained my believing "machinery" to believe that ever I have turned the sand. But the more I think of it the more I relent; and the bent machinery revolves a little slowly in a jingle-joggle sort of way. If it does work as stated, at all times, and in other people's hands, the more credit to you. Page 311.

MIDDLE.

A living machine without a heart.
With no tender throb in any part.
Of iron rules a slave, I ween.
It bows at the throne of King Routine;
It's born of the crowd, and dies alone.
And spares no life, not even its own.

I think it probable that W. W. McNeal is right in claiming that the bee is entirely destitute of love for any other living thing. It has a lot of country to take on for its lack of personal affection. But when he comes to speak of the bee's reasons for action he gets woefully beyond his depth, it seems to me—as most of us do. In consciousness and mode of mind action, living creatures differ much one from the other; and all differ, almost immeasurably, from the human creature's way of thinking and feeling and intuition. A squirrel is conscious that a surplus of food can be turned to future good account. Many other animals will wantonly destroy their own food (all but a few mouthfuls immediately in front of their eyes) even with starvation as the result. This sort of thing is consistent with the personal rules required to keep it so. A cow equally likes a clean bed, yet with disgusting unconsciousness defiles it and everything else in the vicinity. A man sees a fellow man with a guilty-looking face, and is off with his pain—so such an extent often as to be obliged to turn away his eyes. A bee sees a fellow bee half crushed, and in all probability has not the slightest idea that there is any pain Involved at all. If I were a man, I'd be more in favor of the bee's way of doing things, when the weather (see above) has allowed us to see this fecundity of insect life. I can safely say that they are more prolific than the breasts of the queen-breeder in most cases. The queen-breeder is more often enticed into nurturing in the strong season. His eggs hatch in the crowded drones, and rear many drones in March. I can readily believe that drones would mostly get through the mails all right—except when subjected to freezing. If I remember aright, those who have tried to destroy drones-eggs and drone-brood, without destroying the combs also, have found it a very difficult thing to do. But we'll give you a good, long credit-mark for your experiences and success. A queen-breeder might think it worth while to gain a much more moderate time six weeks. And the actual breeding season might wish drone-eggs from afar to cross stock on hand. Page 307.

THIN BOARDS AND SECTIONS FOR KEEPING HIVE-RECORD.

Mr. Davenport's thin boards, 4x4's, make excellent records, no doubt; and spouting Detroit, can as we fathers occupy our own sections. The mode of keeping a hive-record seems to be. But we'll give you a good, long credit-mark for your experiences and success. A queen-breeder might think it worth while to gain a much more moderate time six weeks. And the actual breeding season might wish drone-eggs from afar to cross stock on hand. Page 307.

CLAREMONT A MODEL CITY.

We have a very exceptional society here in Claremont. The metropolis of California, "Our Tribute to Christian Civilization." The unwritten law of the college is, "No Tobacco; no lewdness." I rejoice to say that out of eighty graduates which will be our number now in a few days—our first class graduated since I came here in 1894—all but five have been Christians. Two of those five were members of churches, and one of these is now preaching the gospel; two others, though not professing Christianity, were very intimate with me. They possessed the Christ spirit in a marked degree; we of our 200 students, one-half the residents in voluntary Bible-study classes. We see, then, that our unwritten laws are, and will be, more potent and influenceful than written laws usually are. Thus it will be easily understood why Claremont streets are so free of tobacco. Barely is the smoker seen, and almost never is a young man, and never a boy, seen with the insignia of slavery and short life—the cigarette—reaching from his lips.

I need not say that Claremont is a good, clean place in which to keep a boy. We have never had a case of any kind, being reared in Claremont. Every head of every home circle wishes his boys—how good that I do not need to say girls; (God bless the girls, and help them)—that they stop not with avoidance of the dirty habit, but work with all their greater power to keep the boys from its filthy clutches—to let tobacco entirely alone. Even the man enslaved to the habit hopes his boy may be kept from it. I never heard but one smoker say that he wished his boys to follow in his steps. I am glad indeed that he was so exceptional. But there are few Claremonts. And the great question is: How can we keep the young from this befouling habit, that strikes even at the very health and life of our splendid American boys? And how from the other dangers that lurk to entrap and tarnish our dear ones?

THE BOY AND THE GARDEN.

It has been true—it is true to-day—that Satan is on the eager watch-foot for illers. He knows that they are easily caught. To get the boy or girl thoroughly interested in some good work will more surely rob Satan of his power than aught else. The home circle can undertake no more hopeful or important study than that which will employ all the hands and moments of the boys and girls. Even the city will furnish gardens. We all remember how the governor of Michigan helped the poor by stimulating the growing of potatoes on the vacant lots of the city. Can we not employ the hands to secure the garden, helping at first to cultivate, to plant, and to clean? Let us insist, however, that it all belongs to the children. Let us raise the neat cultivation, the straight rows, the beautiful, thrifty plants; let us so advise and direct that there may be no, or few oth-
ers. Let the children seek the market, prepare the vegetables, etc., in neatest fashion, do their own selling, and, most important of all, let them have every cent of the proceeds, to spend as their very own. If rightly guided—and the thoughtful home circle will always keep guidance in mind—the money will not go for tobacco, nor nonsense. Very likely it will go for books or papers that will guide to better profits. How rich is the culture that comes from such a scheme, well and successfully carried out! It will surely be the best school the child will ever attend.

I believe in education. I am sure no class can have too much. Were all our people thoroughly and wisely educated, most of the evils of our present society would disappear. I believe the educated farmer may exert a power for good that any man might justly envy. I talked this to my boy long before he entered college. I believe that the teaching that follows boyhood is the teaching that tells.

My boy, before he hardly reached his teens, had such a garden as suggested above. He also had a valuable partner—his younger sister. He also had two very interested spectators to advise, direct and encourage. They were the "other" part of the home circle. That boy not only secured spending money—but of all, he acquired such a love of the work, that he looked towards agriculture during all his college course, and to-day is an enthusiastic tiller of the soil. He has no use for tobacco, and if he ever uses profane or unclean language, a knowledge of the fact has never reached his father's ear. That little garden was a garden indeed. In it grew richer and better plants than celery or asparagus.

There are gardens and gardens. Setting the table may be the garden for the girl, or she may have a veritable flower-garden that perchance may take her into the sunshine and pathway to robust health. We must secure employment for our dear children. Their good and the safety of our country demand it. He or she that lets the club, business, society, or even church duties, rob the children of the care and thought that will secure to them habits of thrift, industry, and patient continuance in well-doing, is making a perilous mistake. He or she who keeps the little hands wisely employed, and the little mind interested in all that the hands find to do, is the good angel of the child. May we not hope that there will be just such good angels in all our home circles? May these good angels be so wise and happy that the work of the child may be at the same time its best play.

MIMICRY.

I don't mean making faces. Bees and wasps are usually beautifully yellow and often brilliantly striped. They love sweets, and so gather thickly about the nec- tar-bearing flowers. Two-winged flies hover, and for like purpose, about the same flowers. These flies are also yellow and beautifully striped. Often they are so like the bees that only sharpest eyes can tell which is fly and which is bee or wasp. Why this resemblance in color and markings? For the bee and wasp have a sting. The bird picks up the handsome wasp only to feel the cruel smart, and spit it out, with a lesson that will save all other wasps from attack by that bird.

The fly has no sting. It could not hurt the bird, and doubtless would be a delicate titbit for bird or youngling. Yet the fly has the wasp color, and the bird is fooled by this, passes the fly, loses the tender steak, and so the fly owes its life to its color-markings.

It is good to get our children interested in just such interesting things that are thick all about us. The cabbage butterfly in its black-dotted robes of white drops its green eggs on the green cabbage-leaves. Their green hides them from bird and insect; and so they are saved to life by mimicry.

The weasel is white in winter and brown in summer, and so profits by its color. Polar animals are white. Who of the children can tell why this white helps the weasel and the polar bear?

AN APARTY OF MR. JOHN W. BAUCKMAN, OF FAIRFAX CO., VA.

DESKS FOR GENTLEMEN AND LADIES!

 THESE DESKS are made of quarter-sawed oak, first-class finish, well put together, and will please every purchaser. They are an ornament to any home, as well as being a useful necessity. Would make a FINE GIFT for father, mother or sister.

The Combination Desk and Book-Case is just the thing for a farmer or business man of any kind, to keep his private papers in, and for his books, etc. The drawers have locks, and there are a number of pigeon-holes inside each of the desks shown herewith.

The low prices quoted are f.o.b. Chicago. Send for free catalog. Address,

The Royal Star Combination Game-Board Co.,

773 to 779 Carroll Ave., CHICAGO, ILL.

[The above firm is entirely reliable.—EDITOR.]

Combined Desk and Book-Case
Size, 46 in. high, 36 in. wide.
Price, $13.75.

Ladies' Desk
Size, 40 in. high, 25 in. wide, 15 in. deep.
Price, $8.50.
$15,000 in Cash to be Given Away

The Press Publishing Association will give $15,000 in 1,000 Cash Prizes to those making the nearest estimates on the combined Official Vote of Ohio, Massachusetts and Iowa, cast for Governor on the 5th day of November, 1901.

Estimate the total vote in these three States combined for Governor and send your estimate and subscription to the American Bee Journal, and you will receive a certificate, which will entitle you to participate in the distribution of the $15,000 to be awarded by the Press Publishing Association, of Detroit, Mich., to those making the nearest estimates of the Official Vote for Governor in the States of Ohio, Massachusetts and Iowa, to be determined by the Election held on the 5th day of November, 1901.

We have made arrangements with the Press Publishing Association, of Detroit, Mich., to enable our subscribers to participate in the distribution of these magnificent prizes, amounting to $15,000.

Our Offer: Until Further Notice, every one who sends us a sufficient amount to pay his or her subscription to the American Bee Journal to the end of this year (1901,) provided the subscription is in arrears at least since Jan. 1, 1901; or to any one sending his nearest $1 for an average in advance of next Jan. 1, 1902, will receive a certificate which will entitle him or her to participate in the distribution of the Prizes. No advance is made in the price of our paper; you get the certificate absolutely free.

YOUR ESTIMATE: When you send in your subscription you also send your estimate. Be careful to write your name, address and estimate as plainly as possible. As soon as we receive your subscription we will send you a certificate of the Press Publishing Association of Detroit, Mich., containing your estimate, which will insure you any prize your estimate may entitle you to claim. We will file a duplicate certificate with the Press Publishing Association. Every subscriber may send in as many estimates, and will receive as many certificates, as he sends dollars on subscription to the American Bee Journal.

Valuable Information. To aid subscribers in forming their estimate, we furnish the following data:

The certificates of the Secretaries of the States named showing the Combined Official Vote will determine who are entitled to the Prizes, and the awards will be made within 60 days after the Official Vote is known. The American Bee Journal will publish the names of the successful estimators.

Statement of Mr. W. A. Punges,
President of the Central Savings Bank, Detroit, Mich.: I HEREBY CERTIFY, that the Press Publishing Association has deposited $15,000 in the Central Savings Bank, Detroit, Mich., for the express purpose of paying the Prizes in their contest on the Combined Official Vote of the States of Ohio, Massachusetts and Iowa, and that this fund can be used for no other purpose.

J. A. Punges
President Central Savings Bank, Detroit, Mich.

The cash must accompany your order. The American Bee Journal costs you only $1.00 a year. You get the Certificate absolutely free. Address your orders to GEORGE W. YORK & CO., 144 & 146 Erie Street, Chicago, Ill.
S-frames Nuclei FoR Sale

Can supply 100 or 150 at $2.00 each, with one empty extra comb; 2-frame Nuclei, $1.50. All L.o.H. and B.Q.S. extra. Write.

TENNESSEE QUEENS!

Fine lot of Choice Tested Queens reared last season, descendents of select imported and select golden queens, reared 3% miles apart, and mated to select drones. $1.50 each; un-tested waitressed Queens, from same breeders, either strain, 75c each. No bees over 360 miles from my locality, 50c each. None impure within 1 mile. My bees are reared from selected stock. All colonies received must be free from any outside influence, for they are to be used in establishing new colonies.

Bee-keepers' Supplies.

Just received a consignment of the finest up-to-date stream-lined Hives and Equipments that we have. They are 2 to 3 none. Complete line of Bee-keepers' Supplies on hand. Bees and queens. Catalog free.

THE A. L. REDFORD CO.,

H. O. KALLMAN, Manager,

1024 Miss. Street, St. Paul, Minn.

Have on order over $10,000 worth of Bee-keeping Equipments. A. L. Redfords have the largest assortment of Bee-keeping Equipments on hand. All orders filled promptly and satisfactorily.

PROSPECTS POOR—QUEENLESS COLONY.

There is no prospect of a honey crop here, as it rains nearly every day, and all bees that have been successful in the woods. We had an open winter, and bees wintered without loss. Four of my colonies lost their queens, and have been robbed out. I think it better if robbers get started on a queenless colony in the spring, to let them go, as they are too young to save. The bees are all old, and it spoils a good colony to open the hive before fruit-blossom.

HEADQUARTERS FOR Root's Goods

Bees-Supplies, at Root's Prices. Catalogue free; send for same.
common wrapping-twine long enough to tie around the frame. Then lay a frame on the strings and take the ends of the strings that are under the beehive and lift them up. Against the bottom-bar of the frame on the strings I lay a thin strip of wood the same width and length of the beehive, but long enough to fit inside of the end-bars of the frame, and I am then ready to place the combs in the frame. I have then a sheet of the full size of the frames as the combs will permit, keeping the combs against the top-bar, and then cutting them even on the lower side, so that the strip that fits inside the brood-frame will touch the lower edge of all the pieces of the comb to prevent any cross cleavage, if possible.

In tying the combs I press the strip of wood firmly against the bottom of the comb, and then take the comb against the top-bar of the frame, and hold it firmly till my helper ties the strings, trimming off the strings to within 3/4 of an inch of the knot, always having the knot come on the edge of the top-bar.

I then take another board larger than the brood-frame, and press hard enough with it to level the "crink" out of the comb. I next take the first board, comb, frame, and all, to the hive I wish to put the bees into, put the frame into the hive, and proceed thus until all the combs are used, and the work is done for a week. After that length of time I take the stick off, and what strings the bees have not reached as a rule I get as the combs as if the bees had done the work in the first place, full sheets of foundation excised.

It is always easiest to transfer during mid-bloom.

ARTHUR A. HOSHER.
McDonough Co., Ill., June 5.

Cold Spring Hard on Bees.

I have had to feed my bees a good deal this spring, because it has been so cold until now, when they are beginning to store a little honey.

D. J. BLOCKER.

First Honey Taken Off.

I took off my first section of honey to-day. It is light amber, and has a very fine flavor, but I have had nothing in my past experience that will aid me in determining what source it was gathered from. Come you Pennsylvania readers give me any assistance you can.

I planted two hives here in the spring, May 34, 1900, and kept record of the work in the bees as done by the bees. Do you want the notes? It was something owing to fortunate showers, but not at all my credit.

Bees wintered very poorly in this locality. I have 36 colonies left out of 52, and all but five have been robbed and the stock reduced to store sweet clover as soon as it blooms.

C. SALISBURY.

(Perhaps some of our Pennsylvania subscribers can answer as to the source of that first honey.

Yes, we are always glad to receive notes of an interesting or helpful kind, bearing on the subject to which the Bee Journal is devoted."

—EDITOR.

80 Percent of the Bees Dead.

This is a very poor year for honey in this locality, and 80 percent of the bees are dead. In the evergreen woods the blacks have starved. I still have 16 colonies.

Geo. W. SHREIDER.

Comments on the Score-Card.

As a member of the committee on score-cards, I wish to say to Mr. Hasty that the reason why I ignore drones is because the C. A. C. is the only bee club in North Dakota, and the drones are mostly killed off in an emergency. I believe it is a rare thing to see drones in uncap in September, unless they are queenless.

To that item of "Color and Markings," I would prefix the word "Uniformity," so that it would read "Uniformity of Color and Markings," especially where the golden Italians and the leather-colored compete in the same class.

I like to see the comments and criticisms on the score-card, and hope it will be perfected at the next meeting of the Association.

Juneau Co., Wis., June 10. F. WILSON.

Bees Numb With the Cold—Covers.

Early yesterday morning (June 9) I noticed bees around their drinking-places numb with the cold. I have many times warmed up the water to prevent them from getting chilled.

Last fall white clover was very abundant—almost like blue-grass sod. But it was not protected by the snow during the winter, and much of it was destroyed. It is only to be found in hollow places, and where it was protected.

Basswood trees have no buds, as far as I have been able to ascertain. Sweet clover is very rank and abundant; the yellow variety is gaining a foothold yearly; and its friends are increasing. We have had no swarms as yet, and there are no prospects of any.

Frost and Ice the Last of May.

We had a frost here last night, and ice formed. Bees are killing off drones this morning.

J. F. ANDERSON.
Cook Co., Ill., June 1.

Influence of Queens.

D. B. Norton says in the American Bee-Kepper:

"It is a notion with me that a young Italian queen from good stock is a panacea for all bee-diseases. Many a colony dwindles in spring, or is robbed during a dearth of honey in summer because its queen lacked spirit, either from age or some other cause. If you would see the influence of a queen on her bees, take the mildest colony that you have, and also the most irritable, and exchange their queens and note the effect 20 hours after the queens are liberated."

Wintering in an Inside Cellar.

Ira Barber claims that for the best success in wintering not the slightest quantity of air should be allowed to enter directly from the outside, the slightest breath of outer air making the bees anxious to get out. An experience at Medina makes Editor Root seem inclined to become a disciple of Mr. Barber. Thirty-eight colonies were wintered in an inside cellar in the basement of the machine shop. This basement (perhaps it ought to be called a cellar) is 38x56 feet, with a floor above 7 inches thick, and inside of this was an apartment 4 feet square with no provision for entrance or exit of air other than through several thicknesses of heavy matting and carpeting which formed one of the inside walls. The temperature in the bee-chamber stood at 48 degrees, and there was plenty of fresh air in the surrounding larger room at 40 degrees or more, outer doors or windows being open when necessary to keep down the temperature to 42 degrees. Notwithstanding the bees were left entirely alone, subject to the trembling of feet and the rumbling of machinery above, the first examination (Feb. 21) showed the bees per-
BASSWOOD AND ALFALFA HONEY
in 60-pound tin cans, f.o.b. Chicago—two cans in a box—at these prices: 9 cents a pound for one box of two cans; two boxes (4 cans) or more at one time, 8½ cents a pound.

We have only a limited quantity of the Basswood honey. Sample of either kind, postpaid, 10 cents. Address

GEORGE W. YORk & CO., 144 & 146 Erie St., Chicago, Ill.

25 cents Cash * This is a good time to send in your Beeswax. ** low, upon its receipt, or 27 cents in trade. Impure wax not taken at any price. Address as follows, very plainly,

Marshfield Manufacturing Co., Marshfield, Wis.

Red Clover Queens

LONG-TONGUED BEES ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with $2); or, one Tested Queen free as a premium for sending us FOUR new subscribers with $4.00.

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

All queens guaranteed to arrive in good condition, and all will be shipped, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, $1.00 each; Tested, $2.00 each. Send all orders to

GEORGE W. YORK & CO. 144 & 146 Erie St., CHICAGO, ILL.

Principles of Breeding.

Like those who raise sheep and cattle, beekeepers are breeders of live-stock. The first principle in breeding—the one which every breeder accepts as sound and worthy of all ascending—is that "like produces like." This is a rule as old as the Scripture that affirms its truth by asking "Do men gather grapes of thorns or figs of thistles?" It is easier, for you all remember Jacob, the thifty keeper of the flocks and herds of his grandfather Laban, and how wisely he managed the breeder, with the inevitable result that "the feeder were Laban's, and the younger Jacob's.'

We expect the offspring to be like the parents. We are sure that the little will not produce the great; we are no less sure that the large will not produce the small. We expect the striking characteristics of the parent to be repeated in their children.

The first rule, then, to be kept in mind by the breeder is, that to have the best he must have the best. This is the law. He who violates it suffers the penalty which most of us must bear as best we can, and get along with what is worse than the best. But the law that "like begets like" must not be interpreted too rigidly. Each of the lower animals has two immediate parents, and grandparents without number, and they all have their influence under the same law. The father and the mother are very like alike, and the differences in the grandparents are occasioned by the change in the environment. For what looks like a law of nature is only a law of the environment 

25 cents was a pound — BASSWOOD — a record-breaker. 

Each man is a little landscaper, and he who selects his plants and trees with a view to environment is a true agriculturist. And he who selects his bees and makes them the best he can is a real beekeeper.

HONEY AND BEEWAX

MARKET QUOTATIONS.

CHICAGO, June 19.—New comb honey has not yet reached this market. It would sell at 15c. if choice white, and the amber at 13c. and 5c. The market is entirely thin with exception of a few cases of a lot that we had held for, expecting it would be needed. Prices are high, but shipments will be started by July 1. Very little trading is done in extracted, as large dealers will not contract this season unless for low figures; some sales of amber have been made at 22c. for 5-lb. cases. White is held at 55c. Beeswax sells at 30c.

S. R. BURNETT & Co.

DETROIT, June 8.—Strawberries are taking the attention, very few sales of honey are made, but prices seem to keep up on good lots.

Beeswax in fair demand at 26c.

M. H. HUNT & SON.

CINCINNATI, May 17.—No demand for comb honey, also stock of it well exhausted. Extracted very dull; sales are more or less forced; lower prices from 3c. to 1c per pound.

PETERS Bros.

BOSTON, June 14.—There is practically no comb honey in our market, and owing to warm weather is not extracted. It would appear some new comb early next month. Market for extracted dull, at 95c.

BLAKE, SCOTT & LEW.

OMAHA, May 1.—Comb honey, extra white, 30c. per case, per case, $3.50; No. 1, $3.25; amber, $3.00.

NEW YORK, June 1.—Extracted honey is exceedingly dull and very little moving. We quote for fuel beeswax: 1-lb. case, 60c; light amber, 54c; amber, 50c. Some demand for comb honey at unchanged prices. New crop is now beginning to arrive from the South, and sells at 12c. and 8c., according to quality and style. Dealers are busy buying. HILL & STORKE.

ALBANY, N. Y., June 18.—Honey market is dull with no receipts or stocks of any kind. Demand is between seasons now. Prospect of good winter in the South, and comb honey which is left is greater the portion having been killed by foul brood extended. 12c. up.

BUFFALO, June 14.—No demand at all. Few old lots here almost unurable. When new is ready it will sell moderately well at fair opening prices.

KANSAS CITY, June 14.—Very little old honey on our market but what is damaged by being out of season. We quote for amber, No. 1 grade No. 1 Colorado, amber, 15c. Beeswax firm at 65c.

W. K. CROMWELL PRODUCE CO.

Successors to C. C. CIEMONS & Co.

SANTA FE, June 5.—White comb, 11c. 1c; amber, 4c. per 5-lb. case; 35c. per case, per case, $3.00; amber, 50c. B. R. R. C.

RIO GRANDE PRODUCE CO.

Dealers are very bashful in their ideas, but are not securing much honey as the prices they name. A small way to special trade an advance on quotations is being realized.

A Bee-Keeper’s Paradise.

En route to El Paso—I have just come from a county about 40 miles square that has more bee-keepers to the square mile than any other locality of its size I ever visited. The inhabitants talk bees at the hotels, on the streets, and everywhere, just as farmers talk crops and business in the North. This county produces more honey than any equal area, I believe, in the United States. Some say that its yearly output is a whole trainload of honey; but many aver that this is too low, and that two whole trainloads would come nearer the truth. Of course this great amount doesn’t go all in one lot, but in large and small shipments.

The average per colony is high, and there is a honey crop every season. It is estimated that in this one county, outside of the towns, nearly one-half the population are bee-keepers.

The great bulk of the honey is of the very best, and some of it is literally water-white. There are thousands and thousands of acres of honey-plants on cheap land; and bees—there are not enough to gather it all.

The bees commence swarming early in the spring; and, when the main honey-flows commence, actually stop swarming, destroy cells, kill off the drones, and commence business. Did you ever hear the like of it before? You say, “No, and no one else.” Well, I think I can prove every statement; but for the present I am not at liberty to give the place or other details; but very shortly I’ll tell the whole story, with some fine pictures.

This is only one of the good things in store for readers of Gleanings in Bee-Culture. Send 15 cents for three months’ trial or 25 cents for six months’ trial, or $1.00 for one year and one untested Italian Queen. Send $2.00 and we will send Gleanings one year and one of our Red Clover Queens. Speak quick if you want one.

MR. TOFIELD LEHMAN HIVING A SWARM ON THE RASPBERRY BUSHES.—(See page 418.)
Pan-American Apiarian Exhibit.—We have received the following from Superintendent O. L. Hershiser, which he desires to have read by the New York bee-keepers especially:

NEW YORK STATE APIARIST EXHIBIT AT THE PAN-AMERICAN.

Nearly all the honey in the New York apiarian exhibit is to be replaced by honey of this year's production, as soon as the latter can be obtained from the beekeepers of this State. A goodly number of New York beekeepers are now represented, but it is desired by the latter. It is impossible to name the number of the New York Apiarist Exhibit, with a view to sending in an exhibit. There will be absolutely no expense to the exhibitor further than the extra pains he takes to produce fine exhibition honey, and in the extra care taken to ship the same in a manner to minimize danger of breakage.

Orell L. Hershiser, Superintendent.

Mr. Hershiser writes that everything points to a good convention for Buffalo. The use of the lecture room, committee rooms, etc., of the Buffalo Society of Natural Science has been tendered for the use of the National Bee-Keepers' Association, so they are therefore ready with a good hall. He believes that entertainment will be reasonable, and looks for a very large attendance. We hope there will be an even larger gathering than met here last August. But that was a record-breaker. Will Buffalo equal it? Having the extra attraction of the Pan-American the Buffalo convention ought to equal the one held here in 1893, during the World's Fair.

Fat and Lean Bees.—W. W. Case talks about this in Gleanings in Bee-Culture, explaining how it is that a bee-keeper may be mistaken about the bees of a certain colony being larger or smaller than the average. He says that bees get fat or thin according to food conditions, although the fattening process does not enlarge the thorax. He might also have added that a bee may increase perceptibly in size within a few minutes by filling its honey-sac. He says:

In going through my apiary when honey has not been gathered for a month, I have often been struck with the thought, "Are my bees degenerating?" they seeming smaller in appearance than usual; but after a week's run of honey I am struck with the thought, "What fine, large, shelf-looking bees they are!"

Strong Colonies for Big Yields.—More than one reason can be given why strong colonies should be kept, but it is a very hard thing for a beginner to get away from the thought of the number of bees he has with bees in them rather than the total number of bees in his apiary. Give him his choice between 10 colonies of 10,000 each, and 18 colonies of 20,000 each, and it is quite possible that he may prefer the latter. The 18 colonies look more to his from the outside. It is true that in the latter case he will have eight more colonies, but he will have 40,000 less bees.

Even some with more experience might make the mistake of thinking that 28 colonies of 20,000 bees each would store just as much honey as 10 colonies of 40,000 each. Without thinking, he may say, "There will be just the same number of bees in either case 400,000, why will they not gather the same amount of honey?" Let us figure. Schachinger's experiments showed that when 20,000 bees stored daily 1 1/2 pound of honey, 30,000 3/4, 40,000 1/2. Thus doubling the size of the colony will in all cases give eight times the stores, for a colony of 50,000 bees would not be likely to store eight times as much as a colony of 40,000, and the ratio would vary as the size of colonies would vary, but the general rule will hold good, that in all cases there is great economy in having a little number of a very large colony rather than to have them divided up into a number of smaller colonies.

This matter will appear less strange when it is remembered that a certain number of bees are needed at home to keep up the heat and take care of the brood, and the proportion of these will be less in a strong colony. It can easily be seen that it will not require twice as many bees to protect two frames of brood as it will to protect one.

It is especially recommended to beginners to give this matter careful consideration, and to remember that their success does not depend on the number of hives with bees in them, but upon the number with a strong force in each.

Placing Comb in a Wagon.—Considerable discussion has occurred, especially in Gleanings in Bee-Culture, as to the proper way to place combs to prevent breaking in hauling. All agree that on a car the frames should be placed parallel with the rails, the ends of the frames pointing to the engine. As to hauling on a wagon, however, there was not entire agreement. But a great deal of testimony is to the effect that either on smooth or rough roads the greatest jolting is sidewise, and that the frames should be crosswise, with the ends pointing toward the wheels and not toward the horses.

"Jouncing" Bees Out of Extracting-Supers.
BY C. DAVENPORT.

THE editor of the Bee-Keeper's Review, one of the most prominent men in our ranks, has said that freeing combs from bees is one of the most beautiful parts of the bee-keeper's art, and that the bees must be extracted quickly. Probably all will agree with him in this, for it is certainly a great deal of work to brush the bees from each comb separately, and for a number of reasons escape-boards are far from being as satisfactory to clear full-depth extracting-stories of bees as they are comb-honey supers. Why this is so I will not take space to explain, for I wish to describe the method I practiced last season, to clear full-depth extracting-stories, also comb-honey supers, and what I shall say about this may, in my opinion, be of more practical value to many who are engaged in our pursuit in a large way than the subscription price to this journal would amount to in 25 years.

I feel perfectly free to say this, because the method was not original with me, and I claim no credit whatever for practicing and describing it. Rambler, of California, is the man to whom all honor about this is due, and this method illustrates not only the value of taking out bee-papers, but also of reading all there is in them. For years I have read those rambles of the Rambler, in many of which there was little said about bees, or anything connected with them, and in some of them he had to say about girls rather than about bees—not that I have any objection whatever to reading about girls, (far from it,) but if it was otherwise I should be many times repaid for reading all he wrote.

If some one was to offer me $50 not to practice this method for 10 years, I would not object. I have had an opportunity of using it for 12 or 13 years, and I have always done as well as it was possible to do—far enough.

The method is this: Rambler called a "jouncer," and having, I trust, given full credit to his inventor, I will describe my method of using his invention.

Mine is simply a box about 20 inches long, 12 inches wide, and 10 inches high, ends made of lumber 1 inch thick, and the sides of boards 1 inch thick. Now there is to it—it is simply a box without top or bottom. Rambler's was better, and made somewhat differently, but mine works well enough.

The method of using it is to set it down in front of a hive with this, or extracting story we wish to clear of bees. After taking off the cover and giving the bees a few good, strong puffs of smoke, the upper story is taken off and set down on this jouncer, so it rests across the side, one and one-half inch thick. Now, by the cleats or hand-holes at each end, the super is raised up an inch or so, and then suddenly dropped on the thin side-pieces of the jouncer. This is repeated a few times, and the results are surprising. With full-depth extracting-stories, a half-bushel or so of bees will be on the ground around the jouncer.

As I have said, this is set right in front of their hive and the bees soon crawl in. Until one tries it he would not believe the ease and rapidity with which bees can be jarred or jounced out in this way, after one acquires the knack of doing it just right. It takes longer and requires more jouncing to clear a super of comb-honey than it does an extracting-story, many a time when they fall from the combs, strike the bottom of the sections, which prevents them from falling out. With extracting-combs there is nothing to prevent their falling out on the ground. But most of the bees in the sections can be jarred out in this way more easily, in my opinion, than the supers can be cleared by escape-boards. Besides, what I regard as a great advantage of this plan over escapes is, that the work is done at once, in one operation, as the man goes through the whole section with all surplus that came off the hives. And, seriously, I consider it one of the most valuable things I have learned in regard to our pursuit in many years.

Of course not all the bees can be jarred off in this way, but near enough so I pay no attention to what are left. The honey-house is right in the yard, the windows of which are arranged to allow bees inside to escape, but they prevent those outside from entering; so after jarring out in this way what bees I readily can from a super, it is carried in, and what bees are left are soon find their way outside. When a large number of supers are carried in at one time, they are piled cross-wise of each other. This is important, to have the bees leave the supers and house readily. When the supers are tiered up tight in the regular way, many of the bees will range up and down the whole tier a long time before they seem to feel convinced that they can not find their friends and mother somewhere in the piles.

I have seen it advised where the honey-house was in or near the yard, to carry in the supers—bees and all—or at least carry away of the honey; but I do not believe this advice was given in the use of smoke. But this plan, as no doubt those who have practiced it in a large way will be willing to testify, is a very poor method to practice. It will work in a small way, but when a good many bees are in each super, and a large number of supers are to be extracted, it is not a very pleasant task to see a mass of bees inside that they can not very soon leave by an ordinary escape; and when there are such great numbers they do not, for some reason, seem to wish to leave. I have had large bunches of bees, hundreds and thousands, overhead for days, when there was nothing to prevent their escaping, and after being thrown outdoors many of them would hover around the door and windows, and again enter the supers and leave again. But this would not seem a chance in, the noise and confusion that occurs, or something else, seems to effect or derange many in some way so that they take little interest in the world afterwards, or even seem to know where they are or belong. Some may think that the flying bees are not in the knowledge of their hive; they are bees of all ages—young, middle-aged, and old—and during the working season it is not difficult to tell pretty closely how old a bee is; but the worst part of this method is that it is considered a considerable amount of it may be consumed and damaged by these bees that stay in the house and supers so long, for they do not hesitate to eat what honey they need, or rather apparently, all they can possibly consume.

But what bees I can not jounce out leave the house readily, and with extracting-frames what few bees are left bother but little, even if extracting is commenced as soon as the supers are carried in.

It could be made plain to one that it would be hard, heavy work to jounce in this way full-depth stories that are well-filled. It is not, though, for a man of average strength with 8-frame hives; and it is a great pleasure to see the bees roll out.

Still, many who read this, and try the plan, may regret that I ever wrote anything in regard to it, for by this method it is a very easy matter to break extracting-combs, especially new, unwired ones. I broke a number before I acquired the knack of doing it right, and found out just how hard a jounce new combs could stand. But this was little loss, for I fastened them in the frames again with tine, and the bees attended to the rest even cutting off and carrying out the strings after they had the combs fastened.

Sections, the combs of which are but slightly attached at the top only, can also be readily broken loose by jouncing; but I use bottom starters in sections, which insures the combs being fastened to the wood more than strong enough to endure what jarring is necessary to clear them of bees. This jouncing does not need to be heavy and hard—a very quick, light jounce will accomplish more. The supers should be raised but slightly at first, and the quick, rapid jounce that causes the bees to loosen their grip and roll out.

Prove Theories Before Accepting—A Correction on the Dicke1l Theory.
BY F. GRINER.

On page 359, Prof. A. J. Cook gives as a very interesting article on the Dicke1l and Dicke1l theories. After reading it carefully I am satisfied that no one else would note it as ablly and use all the scientific reasoning correctly. The article contains two minor points which, according to my conception, are not fully true, to which I draw the attention of the Professor as well as the thinking reader.

"Professor Cook says in regard to the queen laying fertilized and unfertilized eggs: 'The queen adds or withholds the sperm-cell at will.' It is pretty clearly proven by the late experiments of Weism, that the queen does lay fer-
An Italian "Atlas of Bee-Culture.

BY C. P. DADANT.

An Italian "Atlas of Bee-Culture."
No. 2. — Some Reminiscences of an Old Bee-Keeper.

By THADDEUS SMITH.

IT is not my intention to go into the history of the first invention or use of the movable-comb hive, as I have done so often in previous essays of this nature. Mr. Langstroth’s patent, I think, was issued in 1852, or about that time, and he admits that some kind of movable combs were used in hives in Europe by Mr. Thomas, of Wiltshire, England, who patented his hive design ten years before his invention or improvements on the hive. I have not even Mr. Langstroth’s book before me to refer to on these matters, and I do not wish to go beyond my own memory for a reference to some numbers of the old American Bee Journal.

The invention and introduction of movable-frame hives certainly created a new era in bee-keeping in this country, and the introduction of the Italian bee about the same time gave a still greater impetus to the business. But the Italian bee would have made slow progress in this country had it not been for the movable-comb hive—probably it never would have been disseminated here at all to any great extent.

When Mr. Langstroth offered the first practical working movable-frame hive to the country, involving principles that had never been used in any hive in Europe, there were many, I have no doubt, inventors of imitators and those who professed to have made improvements upon the standard Langstroth hive by making all sorts of changes, mostly of little, and many of no importance; and on many of these changes and so-called improvements patents were taken; but of these the only ones that I am acquainted with among them were the movable-frame principles of Mr. Langstroth’s patent. Scores of these hives, patented and non-patented, were offered and highly commended to the bee-keeping public, with the object of encouraging the bee-keepers of the country.

We had the Quinby hive, King hive, Alley hive, the Flanders three-cornered or Diamond hive, Thomas hive, American hive, Adair’s “New Idea hive,” the Long Ideal hive, Gallup’s Revolving hive, and— I think I would better end the list here, for time and space forbid the mention of all of them. Mr. H. R. King was probably the most persistent of these so-called new hive inventors, in trying to invalidate Mr. Langstroth’s claims to originality in his invention he made a trip to Europe and spent thousands of dollars for the purpose of collecting evidence to disprove Mr. Langstroth’s claims. He found, as I have stated in the beginning of this article, that frames of some kind had been used by certain ones in Europe some years previous to Mr. Langstroth’s invention; but they all proved so different from Mr. Langstroth’s hive, and so crude in comparison, that it was impossible to have the same claim that was brought to test the matter. N. C. Mitchell was another hive patentee who violently assailed Mr. Langstroth’s claims, and established a new bee-paper for that purpose. In the early seventies the battle of the bee-hive men waxed warm and heated.

The only hive besides the Langstroth, of the new patents, that I was ever induced to try, was that of J. H. Thomas, of Canada. Mr. Thomas set forth the claims of his hive in numerous letters to the American Bee Journal and other papers, and boldly stated that he had “the best hive in America.” About that time I had left “my old Kentucky home, far away,” and was located in the Queen’s home, and I was very desirous to get Mr. Langstroth to come with me the Langstroth hive as made in Cleveland, Ohio, I concluded to try the Thomas hive, and ordered half a dozen.

This hive was an admirable adaptation of frames to the form of the old box-hive—tall in proportion to length and breadth, was well made, and of neat appearance. For surplus there was the ordinary cap, covering a neat honey-box with glass in each end. There were but eight frames, and it was on this account as to the size of the hive that peculiar arrangement were very easily handled. It had a sloping bottom-board with a lot of minor “ fixings” of no especial value. The frames, of course, were large. Soon after this I had the right to use the revolving frame extractor, and the Thomas hives did not suit me. I abandoned the use of them, although I had made a number besides those I bought. There is one about now, in first-rate state of preservation for having laid in the lumber-room of my barn for the past 20 years; others went for hen’s nests and chicken-boxes.

As so many were getting up new hives—patented and non-patented—your humble thought could he get up one, too—of course, an improvement on anything that he had seen or heard of!

I early became greatly interested in Mr. Gallup and his writings, of whom I may have more to say under another head; and this led me to study the so-called model—with changes and improvements, of course! May I be pardoned for giving an extract from an article on “The Hive Question,” printed over 30 years ago, descriptive of my hive, as I wish to make some comments on it in connection with other topics.

“T have made a hive on the plan of Mr. Gallup, that I believe possesses many advantages, and is capable of being used more widely, with the same size frame for all the different styles, than any hive I have prescribed. Mr. Gallup’s hive, I understand, is, about exchangeable with Mr. Langstroth—11 inches wide, 11 inches deep, 18 inches long, or as much longer as may be desired. The frames are hung across the narrow way and can use the same frames—12 in a hive—on top room on top for surplus boxes; 2d, by extending the length to any desired number of frames; frames for surplus honey may be put in each end for empting with the extractor; 3d, it can easily be made a two-story hive with the same size frames in the upper story; 4th, by having movable side-boards it may be made a non-swarmer, on Mr. Quinby’s and Mr. Alley’s principle, and piles of honey-boxes may be put on the sides and top. I have one with 15 frames, 16-pound boxes form the sides, and three 12-pound boxes on top—all enclosed in a box-hive. I have been using this design of hive, and I think that I have hit the golden mean in width and depth,—I call this hive, with its non-swarming and box arrangements, the ‘Quinpye—Reveresible—Removable Frame—Surplus—Reversible—Hive.’ It is said there is nothing in a name, but if I could only get Mr. Price’s ‘Reversible—Removable’ attachment, with the privilege of adding the same name, then I would be satisfied in adopting this compilation for the modified arrangement.”

Of course the name was intended as a burlesque on the many claims of some other hives. But I was in earnest in thinking that I had the “golden mean” in size, and a good thing in a hive that could be used in so many different ways with the same frame, but I never applied for a patent nor offered a hive or a "territory" for sale, though I had material got out in the flat for 30 hives for my own use.

Mr. Gallup had a hive made with open side and side-boxes, as described—the non-swarmer; I put two hives together endwise, and had the "long-ideal" hive. I put two side by side, with one side of each open, and had the "twin hive," and by putting one on top of the other I had the two-story hive or three stories, if desired, as I have sometimes used them.

I have recently read where the writer of the article said in effect: "Before you go into side-storing surplus arrangements extensively, first find out if you have the side-storing kind of bees." I was not long in finding out that my bees were not the side-storing kind, and all my hives except the two stories went to the lumber-room. I thought the hive was a good one and kept it in use, using some of these hives now as two-story—25 frames for extracting; and they make good supers for my chief Langstroth hives. For better wintering I made some with double walls with air-spaces.

In the interim I had found it the advantage to use the extractor, and these frames work well in it. I bought the Peabody as soon as I heard of it on the market. It looks as if it would never wear out, but I got a better one a number of years ago—the Cowan reversible.

It is undoubtedly true that there have been many improvements made upon the original Langstroth hive in the first form given to us, especially the box that contained the frames. The general use of section surplus boxes, and general advancement that has been made in bee-keeping in the last half century, demanded something different—more simple in construction, and yet retaining the same principles of the movable comb that Mr. Langstroth invented; and the great majority of the hives now in use have the same size frame, with the same relative proportions as first recommended by Mr. Langstroth, and that I believe is the way in which the Langstroth frame are in almost universal use in this country.

And where are the hives of King of Thomas, of Flushing; and of the whole list of these so-called improvements to hives? Echo answers, "Where?" We certainly hear but little from them now through the press. And their makers and inventors? Many no doubt, like Mr. Langstroth, have passed over the border to the Beyond, where they are in a place we hope, from till, envy and strife. And the rest of us old fellows—their contemporaries—must, in the nature of things, soon follow. Ontario, Canada.
Swarming—Moving Bees—Queens, Etc.

BY J. M. DAVIS.

LOOK! that's a whoppin' big swarm, whars yer cowbell? Guess I ken stop 'em.

"Oh! Tom, don't hop so excitedly, and don't punch a hole in the bottom of my wax-extractor. Just let them in. I think we'll get left behind the beat music. Hand me that little wire cage off the shelf, and come with me, no danger at all. See, here's the queen climbing this blade of grass. Ah! that's accommodating. Just moving up the grass again, Tom, they are clustering in the top of that apple-tree?"

"Wal, Kunnel, that's the fust swarm of bees I ever saw stopped without a racket. That's the prettiest and longest best swarm I ever saw, why, she is as yeeller as gold. Wat was the skrittin' in the grass fur? That's kings went up with the swarm."

"Well, Tom, you stick to your kings, loyally—but you will have to desert your culors. Queens rule here. I keep one and two and three and four and five, and nearly all the bees in the swarm, and if you want to keep them leavin' with the bees. See this one has her wing clipped."

"I declare, the idea of cuttin' off a bee's wing, Sara Jane cuts her chickens' and turkeys' wings off to keep them out of the garden; but I never'd a thought of cuttin' a bee's wing on a saw? You jist clime that tree and saw off the limb for you, Kunnel."

"Oh! never mind doing that, Tom. Please just help me move the old hive back here—that's alright. Now, kindly help me place this new hive in place of the old one, there, now place the caged queen at the entrance over at that shady corner. You will now see how I hive bees."

"Yes, and I told you Kunnel, to let me rap on the old basin, or they will lite out."

"No, Tom, you just wait, see they are coming down to the new hive on the old stand, and are going in nicely—now you may unstop the cage and let the queen go in with them. See how quick she went in; now the job is done, they will all be back in a few minutes, and soon be at work again. As you see, he's got the imported bees tight, and have their flight; so let's take a look at her ladyship, the queen.

Why, yes, they are working as nicely as any colony in the yard, although they haven't been here two hours. I will first remove the screws that hold on this frame covered with wire-cloth, you see they have all gone down. This frame is two inches deep, but when we arrived it was full of bees clustered so as to relieve the brood-chamber of as much heat as possible. In warm weather they need fresh air, therefore when we move them far, an extra space for a part of them to cluster in should be furnished, and the hive covered with wire-cloth, then there is less danger of fanning the bees, and of losing them down."

"What's thet sponge for Kunnel, tha don't cypher do tha?"

"No, Tom, that held their drinking water, see [squeezing] in there, Tom, that's a good thing. This enable them to keep the young brood alive during the journey. A few folds of old linen, or cotton cloth, answers very well soaked with water, and laid on the frames as was spoiled here.

These corrugated sticks were put in to hold the frames apart, one at each end on top and one in the center at the bottom. I will place them in this new hive as I remove the frames and then I won't be bothered with the corrugated sticks in the bottom."

"Why, Kunnel, they seem to fit jist as well in this gum as t'other. How do you hapan to git 'em so alike, four hundred miles away?"

These pieces are made and shipped all over the country: every piece fits any hive, no matter if you buy it in Australia. It would be a great help to us for all beekeepers to use a standard frame; and I will be glad to see one adopted. See, here is the queen and a fine one she is. She is just three years, or a trifle older, and you will have to rest after her sleep. Notice the shoulders and longer than t'other colony, but not so party gold-like, as t'other one, and these bees are longer too, but three strips of gold around them. T'other was nearly all gold lookin'. Say, Kunnel, what on earth is she crawling like that, do you know? She has got to rest to get her lungs all dry."

"Ha! ha! why she is depositing an egg. Tom, see, she is through, and peeping into other cells to find an empty one there, watch her."

"Now, if that ain't funny, didn't she hump that long back and crawly like, Tom. Say, Kunnel, I heerd of hens layin' two eggs a day, but I never bleved they cud do it. Look, that old huzzy is humpin' her bak agin. Well, that's three in a minute and a half, is she all eggs?"

"Just like them nearly all. I could see you had sent a box from four to four thousand eggs in a day of twenty-four hours. You see, they do not stop at night. These eggs would make a pile about as long as the queen I think."

"True, whis', and I reckon them Italian chickens and geese and turkeys an' ducks. Can't you 'port'em Kunnel?"

"We could get them, Tom, but they would be no better than yours, you prob'ly got two or three thousand bees. You see, they are in three long lines, climbing around, just going about as you'd think the queen was waving her handkerchief, and here I've been over two hours without going up to see whether she was dead or alive. I became so engrossed with my bees that I forgot everything, and I just now remember I haven't had my bread and dinner. You see she pets me some when I've been away."

"Thanks, Kunnel, I just jotted of it, Bil Johnin' sed he'd cum to my house at ten o'clock to buy my yearlings and I think I will go out an' help you. Jake is a peart lad, jist twelve yest'day an he's mitty fond of bees. I see your wife shakin' that 'kerchief at you, and you had better go, or she will be after you. Good evening, Kunnel."

"Good evening, Tom, I shall expect you."

"Good mornin', Kunnel. Jake and me hav been here two hours and Sara Jane shet we would be late."

"Good morning, Tom, and Master Jake, I am especially glad to see the little boxes, and the bees in the end. Tom, you see the bees are cross early in the morning. The sun has warmed them up now, so we will get to work, everything is ready."

"Well, Kunnel, Johnin', they mighty struck and ses he's goin' to be a bee-keeper and get some hidalan' bees."

"Alright, my boy, I will help you get started. Now bring out the wheel-barrow, and nine dry combs, while I start the smoker, I always have it handy—but use it as little as possible. I find cedar bark, well packed, lasts longer, and gives the best volume of smoke of any fuel. Here is number one, see, I gently pry off the top, and use just a little smoke, push several frames just a little nearer together, so as to get room to draw out a frame or two of the bees. You see, the bees give a quick jerk, which you see clears the comb of most of the bees, and this long turkey feather soon gets off the balance; now as we have out three frames of honey, I will put in one of the empty combs every day, I shall do a full one. Here is one full of honey, but not capped; we will leave that as it is too thin when not sealed to make a good grade of honey. It is not ripe. After extracting this honey, we will exchange the empty combs with number two, for her full combs, and so on through the apiary. Tom, draw your honey-knife across the sharp edge of the cross-piece over the uncapping can, to clear off the honey, and while the knife gets gummy put it in a bucket of water, which dissolves the honey, and every time you take off the cappings nicely. Here is a new tender comb, and I will have to turn the extractor much slower to prevent breaking the comb."

"Tom, the sum of these combs are made of black wax, and sum of white wax, what do they get the different colors?"

"All combs are like this new one when first made, but become dark with age. I can shake a comb from a jar and make it as thin as a yearling, or a piece of thistle, when the leaves are only six years old, but I get just as nice clear honey from them, as from these new ones—besides they are tough and stand more rough handling than new comb."

"Tom, Kunnel, here is a low gum. What we gon' to do here?"

"Let us see how they are getting along. Oh! nicely, they are sticking on little bits of white wax along the top cells, and are crowded with bees. Hand me that queen-excluding zinc off the wheel-barrow, and I will put on these freshly extracted combs, which will put them right to
work in the super. Jake, you run up into the extracting room and get me my empty frames for the next hive. Well, this is the last hive, and we take about four thousand pounds in ten and a half days. Now, I want to arrange cells for a few hundred queens. We will not need our smoker, as I do not breed from cross bees.

"Watt's them little yaller things you're gittin', Kunnel?"

"Queen-cells, Tom."

"They is mighty purty, Kunnel. Does the queen stick them on the little stick that way?"

No, Tom. Queens do something except deposit eggs. My little daughter, Annie Dane, makes these for me, it is just fun for her, and saves me a great deal of time, as I use hundreds of them. Now, this hebet child is only eight years old, an makes such nice little things! Looks to me like it would take a regler jneler to do sich work, how on aarth does she make them so thin and smooth at the mouth and so round and smooth?"

"I will lend you a book, written by Doolittle, that explains this fully, and let me say right here, Tom, I would not go back to the old method of queen-rearing for one thousand dollars cash. That book is worth its weight in fine gold."

"Well, Kunnel, I will put it under my pillow every nite and bring it back soon as Sara Jane and me and Jake reads it; an we will be mity proud to read it. Watt's that quill spoon, Kunnel?"

"This is to transfer the larve from the worker-cells to the queen-cells. I will show you the modus operandi. Here are eighteen cells in this hive nearly ready to cap over, and four cells that will be futher, and rather smoother. I always destroy such cells, so I will take these four, and use their royal jelly to put in these new cells—hand me the stick, Jake."

"Hey, Kunnel, here's a worm in this one, is it a moth?"

"No, Tom, it is a young queen, see I can throw them out this way, and dip up a small quantity of the royal jelly with my quill spoon, and place it in the bottom of the new queen-cells, thus newy twenty cells, and I can get the larve from the 'Berberini' imported queen. See, I remove this dummy first, and find the queen."

"There she is, Kunnel, on that frame."

"Thanks, Tom, your eyes are keen. You see I can not afford to risk dropping so fine a queen in the grass or to injure her, therefore I never take any chances. I will just take this frame and leave her in the hive. See, here is plenty larvae just the right size, about twelve to twenty-four days old. I slip my quill spoon under them this way, raise them out and slowly lower them into my queen-cells, until the point of the quill just touches the royal jelly at the bottom, and by drawing it back, the little larvae sticks to the royal jelly which is in it, and then gently ease it into place."

Now all the cells on this stick have larve in them. I will place it between these two combs of brood in super of number 50. See the stick fits tightly in this frame half filled with comb, and it will help keep the cells warm, as the bees cover these comb all the time."

"Why, Kunnel, won't the little queens fall out, with the mouths of the cells down the way? And how on aarth do you take little worker-bees an make queens outen them?"

"No, Tom, they won't fall out, the jelly holds them, and its their nature to grow with their heads down. Never horizontally, like a worker-bee. The peculiar food given them creates their shape, and they are in large perpendicular cells, transforms them into queens. Now, that I have my one hundred queen-cells stocked with larve, I will take out some ripe cells."

"Watt do you mean by ripe cells, Kunnel?"

"A ripe queen-cell is as easily distinguished as a ripe apple. See this stick of queen-cells. The points are all light-colored and pointed, these will be not be ripe for sev- eral days yet. These must be put up to-morrow. See they have blunt flat ends that are brown and rough. The bees knowing that the young queens will want to come out to-morrow, are helping them by trimming off the points of the cells. I take them off the day before they are due, and carefully place them in the half-inch holes you see in this block, with the points resting on the little wool cushions so as not to jar, or injure the young queen. I have only twelve ripe cells this time. Tom, here is what we call a queen-nursery, which is merely a very small swarm of bees—enough to cover well, two or three Langstroth combs."

See this patch of brood? I place the cells thus, just above the brood-comb, I put in temperature, no danger in pressing a Doolittle cell into a comb that way, but a very light pressure would destroy a natural cell. This nursery has been queenless two days, and will gladly accept the cell. Now here is a nursery containing a queen that I wish to take to-night. Here she is; see I remove the cork in the end of this cage, and pick her up by both wings poke her head in the hole from which I took the cork, thus. See, she went in nicely, and to keep her there, I place the end of my thumb over the hole. See, I will get about dozen worker-cells not too young. Now all are in, I replace the cork, tack on the cover, thus. Now I will put on a one-cent stamp and send them to the post-office. I will have to protect the cell, or the bees will destroy it before they miss their queen. This wire-cell protector prevents this, and by the time the young queen emerges from the cell, they will have discovered the loss and will gladly receive her. In two days she will be laying and I will ship her, give them another cell, and you done the rest.

"Well, Jake, here is the new hive with foundation, all ready to hive your swarm on. You shall have a nice queen, a descendant of the Berberini stock, as soon as your colony is ready for her, and I predict that a progressive young bee-keeper will make his start with this colony."

"Progressive Bee-Keeper."

Questions and Answers

Conducted by

Dr. C. C. Miller, Marengo, Ill.

(THE Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—Editor.)

Swarming—Long-Tongued Bees.

I take some encouragement from the letters of C. H. Harlan and F. M. Creighton, page 398, in knowing that sharp eyes are upon me with kindly hearts behind them. Mr. Harlan's statement is exceedingly interesting, and I am wondering whether he has exceptional bees or an exceptional locality. I wish he would give a little fuller light upon it. When he hives the first swarm in a new hive, if I understand him, he cuts out all queen-cells but one in the old hive, and then a little after this a swarm-issues with the young queen from the cell that was left. Now, how long after the cutting out of the cells does this swarming occur? Then he does mean that from this same old colony a third swarm will issue six or eight weeks after the issuing of the second?

Mr. Creighton thinks that long tongues would be of no advantage in his locality. He is no doubt in a very large company who think only of red clover as the one honey-plant, give value to long tongues. A correspondent in the Southland Queen speaks of a honey-plant with tubes so deep that the bees only get part of the nectar, and he thinks long tongues are needed to get it. Mr. Doolittle says, page 292, "long-tongued bees would be an advantage to those residing where red clover and other long-tubed flowers abound." (Italics mine.) Is it not possible that these long-tubed flowers are generally distributed everywhere? Does Mr. Creighton know that when he finds his bees there are no flower-tubes so deep that his bees can not reach all the nectar in them? If he does not know this, then he does not know that long-tongued bees "would store no more honey" for him. If he does know it, will he kindly tell me what he knows? But how all this does apply any hat with him, and hurrah for the bees that don't swarm, in preference to the ones that get the red clover honey. C. C. Miller.

Swarm Left After Being Hived.

At noon to-day I had a large swarm of bees, then set the hive beside the old one that the bees came from, intending, when I came home from the shop at 6 o'clock, to change places with them, putting the new one where the old one was; but at 6 o'clock there were no bees in the new hive. Do you think they went back into the old hive, or left for
the woods? The entrances both faced the same way, and were close together. The new hive contained full frames of comb with a little honey in some of them. CONNECTICUT.

Answer.—I don't know, but I'm afraid they went to the woods. At any rate, without knowing anything about the cases except that 100 large swarms after being hived had deserted their hives, I should feel pretty safe in saying that not more than one or two of the bees had gone back to the hive from which they came. You ought to be able to tell something about it by the appearance of the old colony. If the swarm did not return to it, the scarcity of bees ought to be noticed. The position of the hive had no bearing on the case, except that it would help to make the bees desert if the hive stood in the hot sun. The chief factor in inducing a swarm to desert its hive is heat. Be sure that the hive is very open at the bottom, and for a day or so it is well to have the hive in the shade if the hive does not stand in a shady place use some means to shade it, if nothing better to cover it with an armful of long grass or hay, anchored down with two or three sticks of stove-wood. Some make a practice of giving to a swarm a frame of brood.

Self-Hiving Arrangements for Swarms.

Can bees, when swarming, be transferred to a new hive by closing the opening in the old and new hive so as to be queen-tight, except a wire gauge connecting the two hives through which the queen could pass into the new hive, and the worker-bees to pass out and in as usual? If this plan would not work at all, please say what the objections would be.

Answer.—Several different arrangements have been gotten up on the principle you mention. I don't know enough to tell you exactly as to the objections, but I think none of them have given enough satisfaction to be continued.

Are Bees Taxed in Wisconsin?

Are bees assessable for taxation in Wisconsin?

Answer.—I don't know. A lawyer, or an assessor, ought to be able to tell you. There is no reason why they should not be taxed as well as other property.

 Wants to Be a Big Bee-Keeper.

I am a boy of 16, and I love to handle bees. I have an apiary of six colonies, and would like to enlarge it to 75 or 100 by next spring. I can buy bees in this county at from 50 cents to $3.00 per colony in box-hives, and I think there will be a boom in bee-keeping in this part of the country in a couple of years, as the little open field has been the one that save the existence, and the famous alfalfa is taking its place. There will be thousands of acres in alfalfa. My apiary is situated on the banks of Big Pipe creek, and its fertile valley will yield acres of alfalfa. The farmers can't get a stand of red clover any more, and almost every farmer has a patch of alfalfa started for seed, and in three years the Big Pipe valley will be all alfalfa. Will the bees work on alfalfa in this country? How can I start a big apiary here? I have the beehive and nothing will stop it but heats of colonies of bees.

MARYLAND.

Answer.—Alfalfa is grown on a large scale in the West, and many tons of alfalfa honey are secured, but I have never known of its yielding honey anywhere east of the Mississippi. To decide the matter for your locality, wait till alfalfa has been in bloom a few days then watch to see whether bees are busily engaged upon it on bright, hot days.

If you want to run your six colonies up into the hundreds, I will be advisable for you to gain a full knowledge of the business by carefully studying one or all of the books on bee-keeping you can get, and also gaining practical knowledge by actual work with the bees. By studying a good bee-book, you will learn something about the principles of bee-keeping that will allow you safely to take in your own hands the matter of increase if you do not prefer increase by natural swarming. If you want to increase from six to 75 or 100 this year, it should be mainly by purchase. Aside from what you purchase, it will hardly be advisable for you to increase the six to more than 18, and 12 would be better. Your increase of knowledge and experience should keep you in line with your bees and the coming in of the old and outrun it, and unless you have had considerable experience with bees it might be better not to increase this year, either by purchase or otherwise, to more than 25 or 50. When you have thoroughly studied your text-book there will be questions arising to trouble you, and it will be a pleasure to help you out in this department.

Any Nectar in Mullen?

Is there any nectar in the mullen-bloom? IOWA.

Answer.—I don't know. I never saw a bee at work on it, but it is not plenty where I live.

Requeening by Hiving Swarms.

I have some colonies of bees that are building up slowly, the queens being probably old or inferior. If I remove the queens and in a day or two a new swarm in with them, would you approve or disapprove of this plan of queening them? If it meets your approval, would you give me a first or second opinion on it? WASHINGTON.

Answer.—It would probably work all right. Unless the colonies are very small it would be as well to use second swarms.

The Georging Bee-Veil.

A correspondent writes in defense of the Georging bee veil, referring to page 313, and says that he has used just such a veil himself in the hottest days without infliction punishment on himself, and thinks it "the all-around best for beginners." He says:

"A beginner doesn't want a patent bee-veil, nor an expensive one, nor that is hard to make, bungle some to wear, or easily torn when worn among trees and bushes. A veil, the whole of which is made of bobbinet or cape-lace, may do very well for a regular bee-keeper, as it will keep off the meanest day ever sown or worn. But the beginner will not do so well for a man or woman needing one only occasionally, and then perhaps in climbing a tree after a swarm. Did you ever try the bee-veil, Doctor? If not, your criticism is not up to your usual grade."

I may say in reply, that I hardly see why a beginner should not have the same kind of a veil as a regular bee-keeper. The bobbinet veil I spoke of wearing is not patented, nor expensive, it is simpler to make than the Georging, and it is not so easy to make, nor is it as easy to work with, even in the hottest weather. A veil is more easily torn than cheese-cloth, but I have little trouble with its tearing, even when climbing trees. I do not know that there is likely to be clearer sailing in the apiary of the beginner than in that of the veteran. The beginner in bee-keeping is likely to have his place just as well kept as one who has kept bees for years, and in either case I should rather have a veil that requires care to prevent tearing, than one that would be uncomfortably warm.

No, I do not remember ever to have worn a veil of cheese-cloth. Neither have I ever worn one made of woolen flannel. But I know without wearing a woolen-flannel veil that it would be warmer than one of cheese-cloth. Do you really think I can not know that a cheese-cloth veil would be warmer than a woolen-flannel veil, without actually wearing it? For me the most open veil I have ever worn is a punishment on a very hot day, and I doubt that I am more sensitive in that respect than most persons. So I should not advise the general use of cheese-cloth for bee-veils, either for a beginner or a veteran. If any one is so exceptionally constituted that he will feel no inconvenience on the hottest days from a cheese-cloth veil, by all means he should use the closer, firmer material.

C. C. MILLER.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, and use the Bee Journal as a guide to success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.
**The Home Circle.**

Conducted by Prof. A. J. Cook, Claremont, Calif.

**THE TRUE HOME THE CORNER-STONE.**

I need not say in these "Home Circle" papers—I need not say anywhere, for it surely goes in all our blessed country without saying—that the true home is the very corner-stone in the structure of society.

The child that knows no home is bereft indeed. The child that knows not the true harmonies that alone can make the true home, loses the best that can enter into the life—the soul—of any child.

I feel all this in other form before. It will bear repetition. I may wisely say it over and over. I hope my readers may take up the song and give it warm, glad utterance. Let us wake in the hearts and minds of all our dear children, the idea of the blessedness of the best home, that we may beget in them an absorbing ambition each day to be the head or centre of the very best home felicity. To this end let me have all your ears to-day as I press the importance of our home.

**SPEECH IN THE HOME.**

I am a believer—a sincere believer—in prayer. The man whose life is not braced and anchored in prayer lacks a best help to make his own life superlatively excellent, and his own home what the "Loving Father" wishes it to be. I wish we might all daily pray: "Oh, God, may the words of my mouth this day and ever be such as becometh the gospel of peace." Of course, good words mean a good heart. "Out of the abundance of the heart the mouth speaketh." So we may build up that prayer, not only within our clean heart, oh, God! But let us apply to all this by the statement of Mrs. Gleenings in the BEE-Culture that $1,059,565,787 is the annual drink-bill of our people. I hope Gleenings made a mistake. I fear it is all too true.

Oh, friends! is there not a terrible pathos in these figures?

A woman comes to our house each week to help us. She has great energy, has marked intelligence, and has a family of bright, winsome girls. She has had a hell of a home. An intemperate husband is her ill—her terrible—fortune. When drunk he is a very fiend, and no one's life is safe. She loved the father of her precious children. Over and over she received him back as the prison-doors unlocked and let him forth as sentence for repeated debauches expired. At last, in sheer despair, she has, with broken heart, sent him forth to return no more. Who of us that have been saved from such woes and anguish, can possibly appreciate the misery and despair of those hearts and that home? Who of us will not say with deeper anguish, We will do everything to remove this anachronism of our day and civilization—the saloon—from our country? And I wish here to speak of one way.

Do we joke at intemperance? Do we laugh and exclaim in merry mood as the poor, besotted wretch passes us by? Or the rather, does our face sober, and our whole demeanor tell of our sorrow and regret for the fallen soul?

Not long since I was in a Los Angeles street-car. At a stopping, we were brought to face a policeman leading a young soldier in soiled uniform, who was staggering drunk. His maudlin utterance and reeling gait caused almost all in the car to laugh, and even jokes were made at this awful sight. I wondered then—I wonder still—how any one could even think to laugh. "A soul on the dozen grade!" Or has such a scene could suggest the Eightsome word. I rode away sorrowing, and have sorrowed ever since when the picture has returned to memory.

Oh, can we not commence so early to impress our children with the horrors of drunkenness, and the awful evils of the drink habit, that they will not only abhor the saloon and all its vile belongings, but will sorrow, and speak grave words, almost before the heart is depicted?

There is another evil greater than intemperance. It is well called "the social evil," as all others sink before it. Yet who has not seen the grinace, and heard the joke even from her whom we claim to be those of Christian tendencies? Oh! fellow parents, let us pray, study, think, plan, that we may so culture and refine our dear boys and girls that they may ever walk in ways of cleanliness and purity, and that they may sorrow with inutterable sorrow as they become conscious of the ruined, hopeless lives that cloud even our American society. And may never help, by look, word, or act, to add to the gruesome company that form the sorest blot on our body politic.

**CHURCH-GOING.**

I hope there may not be too much sermonizing in this manifestos to our homes. Nearly everybody goes to church here in Claremont. The same is true of Pomona. I have heard it stated that over 90 percent of the Pomonaites, including children, are church-goers. Though Pomona has several thousand people, like Claremont she has no saloon. Church-goers and saloons do not flourish on the same soil.

One of our Claremont citizens is a nice man, and has a nice family. His wife always goes to church. She formerly brought all the children. I often remarked to Mrs. Cook, "Oh! that that man could see his mistake." Later the oldest boy ceased to come with the mother. This summer that boy with two others ran away from home. No one knew where they were for days. There was sold grief in those homes. Would not that father, who had gone to church, given the dear wife the richest of comfort? Would he not have been likely to have received inspiration that would have helped him to say better words and do better things before those bright children? Would he not, more than likely, have prevented that sorrowful episode in the home that all felt to be a disgrace?

Now I notice that the second boy is not coming, and only the little girl keeps the mother company. Here, where nearly every one goes to church, how easy to have kept the boys in church and Sunday-school. We have a model Sunday-school in which splendid men and women in prospective are being beautifully fashioned. I truly believe that if our fathers only knew how such meetings helped to make grand men and women, as well as beautiful and obedient boys and girls, not to say worthy and excellent citizens, they would soon be found of a Sunday morning leading the family to the house of worship. And, oh! how that would rejoice the yearning, lonely heart of the mother.

Two years ago I stepped off the train in the great Grand Trunk depot of Chicago. I had written our friend, Mr. York, that I would come on that train. He had written me that I was to wait till he came. It was in the early evening of Sunday. I waited long. It was not tedious. I never am lonely in such places or at such times. The people, some good book or magazine, always make the hours, like birds, fly by. Later our good friend came. He was lost from church, where he and his delightful wife always aid in the worship.

God be praised that the old American Bee Journal has a Christian editor, who fears God and desires above everything else to keep his commandments. This fact makes for the refinement and betterment of every reader of our beloved American Bee Journal.

---

"Wildwood Aerie" By R. V. Goss—See page 418.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at $1.00.
To Our Shippers.

About May 1st last, we removed our business from the buildings 120-122 W. Broadway to larger and more commodious quarters at Nos. 265-267 Greenwich St., and 82, 84, 86 Murray St., and we duly sent to our friends in the trade a notice of our removal. Shortly after we vacated the premises (120-122 W. Broadway,) one Joseph M. McCaul, rented a portion of our old quarters, and hung out a sign, "Hildreth, McCaul Co., Jos. M. McCaul, Prop.," with other large signs to the effect that his business is "headquarters for honey, beeswax, maple sugar and maple syrup."

The mercantile agencies report that Jos. M. McCaul is the sole proprietor of the new business, and that he claims to have paid to one Henry P. Hildreth (who has no connection with our business,) a consideration for the use of his name.

We will not comment upon the act of leasing our old quarters and exposing thereon the sign, "Hildreth, McCaul Co.," further than to state that we have instructed our attorneys to apply for an injunction restraining the said McCaul from using the name of "Hildreth" in connection with his business in any manner whatsoever.

We value highly the good name and business we have established by many years of satisfactory dealing with our friends in the trade, and we therefore send this notice so that you may not possibly confound us in any manner with the so-called "Hildreth, McCaul Co."

Our firm name remains as heretofore, and all our business is carried on at our new quarters—

Nos. 265=267 Greenwich Street,
and Nos. 82, 84, 86 Murray St., New York, N.Y.

Respectfully yours,

HILDRETH & SEGELKEN.
AMERICAN BEE JOURNAL

THE MODERN FARMER & BUSY BEE.

EMERSON TAYLOR ABBOTT, Editor.

A live, up-to-date Farm Journal with a General Farm Department for Dairy, Horticulture, Livestock Poultry and Veterinary, Home and General News. Edited by one who has had practical experience in every department of farm work. The product of two decades and the result of years experience and study, its rank will grow until it bids for a place in the farm world. For the busy rancher, the vocational student and the rural worker, its scope and present and future value will be seen and acknowledged.

MODERN FARMER,
ST. JOSEPH, MO.

Please mention Bee Journal when writing.

The American Poultry Journal

325 Dearborn Street, Chicago, Ill.

A Journal that is over a quarter of a century old and is still growing. Its success is due to the fact that in every department of poultry work, the fowls, hens and chickens, the price of eggs and other poultry products, the care and feeding of the birds, etc., the same is fully covered by an expert bee-man. Besides this, the editor tells all about California Agriculture and Horticulture. $1.00 per year; 6 months, $0.50; single copy, 10 cents.

The Rural Californian

Tell all about Bees in California. The yields and Price of Honey; the Pasture and Nectar-Producing Plants; the Bee-Ranches and how they are conducted. In fact the entire field is fully covered by an expert bee-man. Besides this, the editor tells all about California Agriculture and Horticulture. $1.00 per year; 6 months, $0.50; single copy, 10 cents.

Barnes' Foot Power Machinery

Read what J. L. Parent, of Charleston, N. Y., says about our Foot Power Machinery. We sell a complete line of Combine Machines, last winter, 50000 hives with 5c, 10c, 15c, 20c, 30c, 40c, 50c, 60c, 10c honey boxes, and a great deal of other work. You cannot make half the amount of bee-hives, etc., to make, and we expect to do it with this Saw. It will do all you say it will do." Catalog and price list free.

Poultry Book FREE, 48 pages, illustrated with a map and table description of our book, the INLAND POULTRY JOURNAL, Indianapolis, Ind. Please mention Bee Journal when writing.

1901—Bee Keepers' Supplies!

We furnish you with The A. L. Root Co.'s IITDS CATALOGues of retail or wholesale prices. We also save you freight, and ship promptly. Market prices paid for these two large catalogues. M. H. M. H. HUNTS & S. HUNT, Beloit Branch, Wayne Co., Mich. Please mention Bee Journal when writing.

BLACK BEES vs. ITALIANS.

I expect to stir up a veritable hornet's nest with what I am about to say, nevertheless here goes:

In looking over the advertisements in Glennialus in Bee-Culture and the American Bee Journal, I can not help noticing that everybody is trying to sell either Italian or queen bees (as they are always the "best"), or is just about to advertise for Italianize common black bees. I wish to make the assertion that the black or brown bee is the best bee for this locality, and for the average person who keeps a few hives and doesn't pay close attention to them.

In the first place, they always winter better here; and the reason for it, is that they have more good, sound, common-sense, and use more judgment, than the Italians, and do not

Prospects for a Large Yield.

Bees watered well throughout this country, and are very busy now making alfalfa and clover. The prospects are good for a large yield of honey. The American Bee Journal comes regularly, and is a welcome visitor. W. H. Horton, Santa Fe Co., N. Mex., June 13.

No Nectar in White Clover Bloom.

We have the finest crop of white clover bloom in this section that I ever saw, but there is not a drop of nectar in it, and as this is the only source for a honey-flow at this time the bees are starved. There has been just enough rain to enable me to make seasonable, and plenty of nice, hot, sunny days, and it does seem as though everythign was favorable, but there is no honey. Some one would like to ask the reason for this, if any one can tell.

M. D. ANDER.

QUEENS

QUIRIN—The QUEEN-BREEDER has now on hand, ready to mail, 500 young, long-tongued Red Clover Queens, Golden or Leather Colored. We have one of Root's best breeders from his $20, long-tongued, Red Clover Queen, and a Golden Breeder which we are told is worth $10, if there is a queen in the U. S. worth that sum. J. L. Gandy, of Humboldt, Neb., tells us that the colony having one of our queens, stored over 400 pounds (mostly comb), honey in a single season. A. L. Root's folks say that our queens are extra fine, while the editor of the American Bee Journal tells us that he has good reports from our stock from west of the Mississippi. We have years of experience in mailing and rearing Queens, Queens positively by return mail from now on. Prices for balance of season as follows:

<table>
<thead>
<tr>
<th>Quantity</th>
<th>Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>$0.75</td>
</tr>
<tr>
<td>2</td>
<td>$1.00</td>

</table>

Extra selected, tested, the best that money can buy, $0.00.

H. G. QUIRIN, Parkertown, Ohio. Parkertown is a Money-Order Office. 27thst Please mention the Bee Journal.

BLACK BEES vs. ITALIANS.

I expect to stir up a veritable hornet's nest with what I am about to say, nevertheless here goes:

In looking over the advertisements in Glennialus in Bee-Culture and the American Bee Journal, I can not help noticing that everybody is trying to sell either Italian or queen bees (as they are always the "best"), or is just about to advertise for Italianize common black bees. I wish to make the assertion that the black or brown bee is the best bee for this locality, and for the average person who keeps a few hives and doesn't pay close attention to them.

In the first place, they always winter better here; and the reason for it, is that they have more good, sound, common-sense, and use more judgment, than the Italians, and do not

Experiences of a Beginner.

Last fall I went to an auction sale where there were a few colonies of bees for sale, and bought one colony for the small sum of $1.00. I placed them in a box, with about two dozen frames, in all from that time until now, have only one of the for left alive to-day, and she is a complete failure. I have had no good show as the bees are doing in every respect, and were from different breeders, all the way from Richland to Washtenaw.

If any queen-breeder take exception to this, all right: but I am through buying Italian queens.

G. R. B. WATTS.

Linn Co., Oriz., June 15.

Outlook for a Fair Honey Crop.

Last March we moved our bees from Fond du Lac County to Richland County, there being but little bee pasturage in the former county, and the locality was also overstocked, consequently they have had but two fair honey crops the past two years.

There is a good outlook for a fair crop of honey in Richland County. It has been quite cool all through the feeding time, did not get very warm, but fast, and we are having warm days and nights now, with a little rain about once a week. There is plenty of clover here, but there has been in the past two years. Brook-chambers are filled with honey, and the bees are doing fine and raising brood fast. Most of the beekeepers are here for working for extracted honey, we being the only ones working exclusively for comb honey.

A. M. REYN. Richland Co., Ws., June 15.

Good Report from Michigan.

Michigan is to the front again with a large honey-yield. Last year my colonies averaged 129 lbs. each of combs, and 15 pounds each of extracted honey—the finest I have ever tasted. And now, notwithstanding the late spring, they are better than they were a few weeks last year. I did not remove the winter packing until June 1, on account of the cold weather. The bees had a hard struggle to feed the young brood up to that time. June 3 they cast their first swarm—one day earlier than last year. In just one week this young swarm had seven brood-chambers filled with honey and comb, and that without comb foundation being furnished them. To-day they have 1 brood-chamber filled, and one section and old comb cast the second swarm—larger than the first—on June 13, and has filled 36 sections of brood-chamber. My large colony—that is, seems to be the most populous—has not swarmed in two years, but it has filled 76-pound sections since June 3, and I will put 74 more on to-morrow. I do not know where they procure the honey, as I have not had time to investigate. There is white clover in abundance, but I have failed to see the first bee on its blossoms this year. I am not using any cotton-seed for reasons, but have a much better and cheaper device, which I will describe later.

Weather Hard on the Bees.

I had 18 colonies of bees, spring count, but two of them were very weak, and have since died.

The weather this spring has been the most unfavorable for many years. April came in cool, dry and cold, with only 53 hours of sunshine the whole month. May was a little better, there being only 67 hours of sunshine, and very cold, and mention the May third, May 21, and May 35 it commenced to rain, and continued cold and rainy, the bees having only about 3% of the sun this month. The weather has been very fine for the past two weeks, and although I cannot see from what source they are gathering, they are storing honey very fast.

I have had only five swarms so far this season, but they are working hard, having just started in the sections.

Basswood is very scarce here, but there are enough of white clover, and this year and white clover; also goldenrod in great abundance. I find many useful hints in the Bee Journal.

C. H. STOUT, Co. X. H., June 14.

Bees Working on White Clover.

There is an abundance of white clover, and bees are doing fine. We have had only one swarm, and have divided four colonies.

A few of the colonies have taken the new variety, nearly all of honey.

C. A. FAIRBANKS. Jones Co., Iowa, June 17.

Bees Rolling in the Honey.

My bees are just rolling in the honey now, and keep busy on both honey and swarms. I have 70 colonies in all.

Do Bees Select Their Future Home Before Swarming?

We are all interested in anything pertaining to the habits of our bees, even it. It does not have a commercial aspect; and any one having a bee section in his yard will know that the swarm is contributing something of value to natural history. Hence, the question of bees selecting their future home before swarming is not altogether without interest. Prof. Cook thinks they always do, and mentions having seen several hovering over the feeding station, and the next day a swarm took possession.

I had the temerity to question the statement that they always select their home before swarming; Mr. O. B. Griffin, of Maine, on page 111, thinks that, “in the majority of cases,” they do not. And now comes Mr. D. H. Metcalf, of Michigan, who thinks (page 157) that “first swarms always do—second swarms, sometimes do, and swarms of seeing ‘scouts’ (as I, being an old soldier, call them) investigating a bee-tree, and one where the swarm has previously appeared, who would have taken possession only he had filled the tree. This looks pretty solid, on the face of it, for the alternative side of the question, and yet it is only what the writers would call "prima facie,” or first-view, evidence. If Mr. E. C. Smith had not raised the swarm issue, and followed it up to the bee-tree, the chain of evidence would be more complete; but I would think in this case would not have been mentioned by Prof. Cook. Have you any evidence to show that the swarm was not already chosen? or some other agents upon which it might be seen? This will cover the whole point of contention.

I think you would like to ask the fundamental question: Why does a swarm cluster at all? There would be no need of it if they had already selected their home. Prof. Cook, in “To rest the queen.” I can think that the Professors were serious when he made that statement. For bees have as much sense as they...

Tennessee Queens!
Fine lot of Choice Tested Queens reared last season, daughters of select imported and select proven queens, reared 2½ miles apart, and mated to select drones, $1.50 each; untested warranted Queens, from same breeders, either strain, 75c each. All been owned more than ½ miles. None impure within 3, and but 2 within 8 miles. 2 years' experience. Discount for large orders. Good customers with dealers a specialty. JOHN M. DAVIS, Spring Hill, Tenn.

Please mention Bee Journal when writing.

Marshall Manufacturing Company.

Our Specialty is making SECTIONS, and they are the best in the market. Wisconsin BASSWOOD is the right kind for them. We have a full line of BEE-SUPPLIES. Write for free illustrated catalog and price-list.

Marshfield Manufacturing Co., Marshfield, Wis.

Red Clover Queens

LONG-TONGUED BEES ARE DEMANDED NOW.

ONE Un tested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with $2; or, one Tested Queen free as a premium for sending us FOUR new subscribers with $4.00).

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The breeder he will use is direct from Italy, having imported her himself. Our worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

All queens guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Un-tested, $1.00 each; Tested, $2.00 each. Send all orders to

GEORGE W. YORK & CO.
144 & 146 Erie St., CHICAGO, ILL.

Please Mention the Bee Journal when writing.

Advertisers....
I think it would have been unwise to depend upon tongue-length alone. But I do insist that the advantage of long tongues has not been proven to be exclusively associated with red clover; and it is possible—not probable, I think—that the gain from other flowers with long tubes may be greater even than from red clover.

Straining Extracted Honey.

Elis Fox gives his plan in Gleanings in Bee-Culture as follows:

I have six large barrels, holding about 600 pounds each, arranged around my extracting-room on a strong bench, with heads out, and manholes-gates near the bottom. Each barrel is supplied with a fine cheese-clot strainer tied securely over the head. I draw the extract from the extra-fine, 8 ordinary, water-pail, and transmit to these barrels through the strainers. This takes out the minutest specks. It is left in these barrels from one to six weeks (according to the time in the season of extracting), when it is drawn off into 9-pound cans, caps screwed down tight, and placed in cases, and securely nailed, ready for shipment. I have practiced this method for the past 20 years, and have never had a word of fault found.

ITALIAN QUEENS FREE

BY RETURN MAIL.

For sending us One New Subscriber for one year, to the American Bee Journal, with $1.00, we will send by return mail, a fine Untested Italian Queen free as a premium. This offer is made only to our present regular subscribers.

We will mail one of the above queens alone for 75 cents: or 3 for $2.10.

Please do not conflict the above offer with the one on another page which refers to Red Clover Queens. For sending us two new subscribers, and $2.00, we will mail free as a premium an Untested Red Clover Italian Queen.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, June 3.—New comb honey has not yet reached this market. It would sell at 1500 lb if choice white, and the ambers at 1280c.

The market is entirely bare with exception of a few cases of a lot that we had held for us, expecting it would be needed. Ad vises that shipment will not be possible until July 1. Very little trading is being done in extracted, as large dealers will not buy more than at low figures; some sales of ambers have been made, 400c. for 50-lb. boxes; delivery; white is held at 55c. Beeswax sells at 32c.

R. A. BURNETT & Co.

CINCINNATI, May 17.—No demand for comb honey. The trade shows no sign of improvement. Extracted very dull; sales are more or less forced; lower prices from 1/2 to 1 cent per pound.

C. H. W. WEER.

BOSTON, June 14.—There is practically no comb honey in our market, and owing to warm weather very little call for it. Are expecting some new comb early next month. Market for extracted dull, at 95c. and 97c.

BLAKE, SCOTT & LEE.

OMAHA, May 1.—Comb honey, extra white, 24-frame cases, per case, $5.60; No. 1, $5.35; amber, $5.60; No. 2, $5.45; ambers, $5.85. We buy and ship comb.

NEW YORK, June 1.—Extracted honey is exceedingly dull and very little moving. We quote for the present: Single amber, 5566c.; amber, 55685c. Some demand for comb honey at uncharged prices. New crop is now being sold in the market, and sold at from 1250c. up; according to quality and style. Lisboa, 75c.; South America, 50c.

ALBANY, N. Y., June 18.—Honey market is dull with no receipts or stocks and little demand. It is between seasons now. Prospect of good year. Honey is being received from the South. But there are left, the greater portion having been killed by foul brood exterminators. H. E. WRIGHT.

DETROIT, June 24.—Very few sales of honey, but prices are well maintained. The new crop will start out at good prices, and with little old honey to interfere will be in fair demand at 275c. and $1.

M. H. HUNT & SON.

BUFFALO, June 20.—Honey not wanted till cool, fall weather. Little old honey here and dragging, 60c. Extracted not wanted. Fruit takes place of honey now.

BATTISON & Co.

KANSAS CITY, June 14.—Very little old honey on our market but what is damaged by being grated. Sales are light at 15c. per lb for best grade No. 1 Colorado. Amber, 18c. Beeswax firm at 25c.

W. R. CROSWELL PRODUCER CO.,

Successors to C. C. Clemens & Co.

SAN FRANCISCO, June 5.—White comb, 115c. at 125c. Estates; amber, amber, $1.50 to $2.25; we quote:

Extracted, white, 55c.; light amber, 45c.; dark amber, 60c. Beeswax, 35c. plus.

Dealers are very bearish in their ideas, but are not securing much honey at the prices they name. In a small way to special trade an advance on quotations is being realized.

At the Pan-American

I can accommodate five or six persons who wish to spend the Pan-American, Rates reasonable. Good car service half a block away. If any wish to correspond in advance, address,

M. RICKARD,

244 Dodge Street, BUFFALO, N. Y.

A Bee-Keeper's Paradise.

En route to El Paso.—I have just come from a county about 40 miles square that has more bee-keepers to the square mile than any other locality of its size I ever visited. The inhabitants talk bees at the hotels, on the streets, and everywhere, just as farmers talk crops and business in the North. This county produces more honey than any equal area, I believe, in the United States. Some say that its yearly output is a whole trainload of honey; but many aver that this is too low, and that two whole trainloads would come nearer the truth. Of course this great amount doesn't go all in one lot, but in large and small shipments.

The average per colony is high, and there is a honey crop every season. It is estimated that in this one county, outside of the towns, nearly one-half the population are bee-keepers.

The great bulk of the honey is of the very finest, and some of it is literally water-white. There are thousands and thousands of acres of honey-plants on cheap land; and bees—there are not enough to gather it all.

The bees commence swarming early in the spring; and, when the main honey-flow commences, actually stop swarming, destroy cells, kill off the drones, and commence business. Did you ever hear the like of it before? You say, “No, and no one else.” Well, I think I can prove every statement: but for the present I am not at liberty to give the place or other details; but very shortly I'll tell the whole story, with some fine pictures.

This is only one of the good things in store for readers of Gleanings in Bee-Culture. Send 15 cents for three months' trial or 25 cents for six months' trial, or $1.00 for one year and one un-tested Italian Queen. Send $2.00 and we will send Gleanings one year and one of our Red Clover Queens. Speak quick if you want one.

Hot Weather Hint.

"Hot weather? Yes; but really not. Compared with weather twice as hot. Find comfort, then, in quoting this. And you'll pull through victorious:

For instance, while you gasp and pant
And try to catch your breath,

--With soda, cream, and lemonade,
The heat at ninety in the shade—
Just calmly and coolly.

These same degrees, with ninety more
On top of them, and so concede.

"The weather won't cool indeed!"

—J. Whitney Riley.

Mr. C. A. Hatch, writing June 22, had this to say:

"We had poor luck in wintering bees the past winter, so we have not an extra-large force of honey-gatherers. I think fully 50 percent of the bees in this part of Wisconsin died. My own loss was about 20 percent—perhaps the heaviest for many years. We hope for better luck next time."

Dr. A. B. Mason, secretary of the National Bee-Keeper's Association, has been appointed judge of the bee and honey department of the Ohio Exposition, which will be held at Columbus next month. A total of only $74 is to be awarded in that department, so the Doctor ought not to have a very long or hard job.

The Doctor wrote us, July 1, as follows about his trip:

"No honey from the world of white clover we have, but sweet clover is getting nicely in bloom, and the bees are busy on it. We have colonies with two, three, and four and a half stories, to give room to the bees, and running over at that, and no disposition to swarm."

Mr. W. W. Whipple and his apiary, of Arapahoe Co., Colo., are shown on our first page this week. Mr. W. is a native of Michigan, and in his boyhood days learned the printing business. He then drifted into western Iowa, in the early fifties, and went to Colorado in 1869, during the Pike's Peak gold excitement. He has worked as printer, job printer, miner, and lastly as a bee-keeper, and will probably follow the latter occupation the remainder of his days.

Mr. Whipple has met with varied success in bee-keeping, but is fairly well satisfied, although he says the bee-keeper has no picnic in Colorado. He must be constantly on his guard to keep clear of that pest—foul brood. When he first went to his present locality there were many farmers who had a few colonies of bees, and when a colony died they would not know the cause, or even that it was dead (and in most cases it was foul brood that killed it), until the colony was robbed of its stores, and they were spread far and near, making trouble for the bee-keepers. Bee-keeping there would be a pleasant and profitable business if it were not for this, so Mr. Whipple says.

They are expecting a good alfalfa honey season this year, as the crop of alfalfa is very forward and seems likely to bloom abun-
dantly. He expected the flow to be about June 20, when there would be busy days, and he thought it possible the "hum of the bees in the alfalfa bloom" could be heard on all sides.

FREE as a Premium
A Foster Stylographic Pen.

This pen consists of a hard rubber holder, tapering to a round point, and as well as a fine nib. The point and needle of the pen are made of platinum, alloyed with a substance of great durability which are not affected by the action of any ordinary solvents.

They hold sufficient ink to write 10,000 words, and do not leak, if kept dry.

As they make a line of uniform width at all times, they are unsuited for ruling purposes.

Pens are furnished in neat paper boxes. Each pen is accompanied with full directions, filler and cleaner.

FOSTER MANUFACTURING PEN ON THE MARKET.

19,000 Postmasters use this kind of a pen. The Editor of the American Bee Journal uses the "Foster." You should have one also.

How to Get a "Foster"

FREE.

Send two new subscribers to the American Bee Journal for one year, with $1.00, or send $1.00 for the pen and your own subscription to the American Bee Journal for one year; or, for $1.00 we will mail the pen alone.

The Bee-Keepers' Guide;
Or, Manual of the Apiary.

By Prof. A. J. Cook.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fatty illustrated, and all written in the most fascinating style. The book also takes the beekeeper to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without The Bee-Keeper's Guide.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, has neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and is also extended to the two new subscribers—simply the Bee Journal for one year.

Send us TWO new subscribers to the Bee Journal with $2,000, and we will mail you a copy of Prof. Cook's book FREE as a premium, Prof. Cook's book alone sent for $1.25, or we club it with the Bee Journal for both for only $1.75. But surely anybody can get only TWO NEW subscribers to the Bee Journal for a year, and then get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,
144 & 146 Erie Street.
CHICAGO, ILL.
**Are You a Member of the National Bee-Keepers’ Association?** If not, you should be. But perhaps you would like to know more about being a member. If so, write to the general manager, Mr. Eugene Secor, Forest City, Iowa, for circulars explaining the objects and work of the Association.

You will remember that last week we began the effort to secure a membership of an even 1000 by the time of the Buffalo convention, in September. Send in the dollars for dues, so we can begin to publish the list of names. We want to receive over 200 during July and August. Are you a member of the Association?

**The Buffalo Convention.—**We have received the following notice and information in reference to the next meeting of the National Bee-Keepers’ Association at Buffalo.

**STATION B, TOLEDO, OHIO, JULY 1.**

Mr. Enslow.—Please say in the American Bee Journal that the next convention of the National Bee-Keepers’ Association will be held in the Soldiers’ and Sailors’ Room of the Society of Natural Sciences, on the 10th, 11th and 12th of next September, commencing on the evening of the 10th. The place of meeting is in the Buffalo Library Building, corner of Washington and Clinton Streets, near the business centre of the city.

Railroad rates will vary in the different passenger association territories from one cent a mile each way to one and one-third for the round trip. Each one can readily learn the rate on enquiry at his or her railroad station.

The Buffalo bee-keepers will try to provide entertainment at reasonable rates for all attending the convention who will notify Mr. Sidney S. Steeper, Holland, N. Y., by Sept. 2. In a letter recently received from Mr. Steeper, he says:

> "I want all who can to come for we wish to make the Buffalo meeting the most pleasant and instructive one that was ever held in America. We will have the cooperation of all the scientific as well as the school boards; then he names some professional men who are interested in one specialty, and will be at the convention to help; and a long letter from Mr. Herrisher closes by saying, "Call upon me for whatever further assistance you may need to render," and Mr. Penton, ex-president of the Erie County Bee-Keeper’s Society, and others, have promised to do all they can to provide for the comfort of the delegates.

As stated in my previous convention notice in the American Bee Journal, there will be no fixed program, and no papers, the time being fully occupied in asking, answering, and discussing questions, except that on the evening of the 12th there will be a joint session of our Association and the American Pomological Society, to discuss "The Mutual Relations of Bee-Keepers and Fruit Growers," Prof. Beach, of the New York Agricultural Experiment Station, and Prof. Fletcher, of the Central Experiment Farm of the Dominion of Canada, will help talk for the bee at that session. It is hoped that much good will result to fruit-growers and bee-keepers from this joint session.

If any bee-keeper who cannot attend the convention has any questions he would like to have answered at the convention, will send them to me, I will see that they are presented. Made this same request in my previous communication, and perhaps you will remember of writing me to the effect that with such a request in all the bee-papers I would be deluged with questions, and in the last week’s American Bee Journal you talk very nicely editorially on the same subject, and still I’ve not received a single question, except about 30 I’ve sent myself, and I have several more in my mind that I’m going to send to the secretary.

A. B. MARSTON, Sec.

---

**In-Breeding,** as treated by C. P. Dadant in this journal, seems to puzzle Deacon Hard-scrabble, a bright writer who has suddenly appeared in the horizon of the American Bee-Keeper. He is confused at the two statements that nature abhors in-breeding, and that 'in natural conditions a colony may be several miles from other bees and probably requires all the drones that it may produce.' He didn’t notice that "may be," says Deacon. You know there are exceptions to all rules, and nature doesn’t in all cases find things to her liking. She’ll remedy that by planting a colony at such swarming-time between the two districts so that the drones can pass the distance between.

**Several Laying Queens in One Hive,**—Swarthmore says in Glenings in Bee-Culture that the secret of success in having several laying queens kept throughout the season in one hive, lies in the giving them all at one time to bees that have been queenless for but three days. "An indefinite number of queens may be confined in boxes or cages arranged in such a way that none can come in contact, yet allowing the bees freedom to go and come, to do as they will."

**Watercress Honey.—**W. A. D. Perd reports in the British Bee Journal that he gets quite a quantity of honey of very good quality from watercress bloom. He says the bees store very fast from this source, and will fill a super in a few days. We have never heard of watercress yielding honey in this country. Perhaps some of our readers can report on it. We understand that watercress is shipped to Chicago by the barrel, being used as greens.

The Illinois State Fair premium list for 1901 is now issued. A copy of it can be had by addressing W. C. Garrard, Secretary, Springfield, Ill. It will be the 45th annual exhibition, under the auspices of the Illinois State Board of Agriculture.

Under the heading, "Bees and Honey," we find the following list of premiums offered, which are "open to the world."

</table>

**Honey-vinegar, 1 gallon, with recipe for making.**

**Honey-treacle, 1 gallon, with recipe for making.**

**Display of designs in honey of beeswax.**

The judges will be governed by the code of rules adopted by the Illinois State Bee-Keeper’s Association. 300 pounds will receive full score for quantity in displays of comb and extracted honey, and 200 points in displays of candied honey. 50 pounds will receive full score for quantity in display of beeswax. Only one entry will be allowed by each exhibitor for any one premium. There is over $300 offered to bee-keepers in the above list. For some years there have been very creditable apiarian exhibits at the Illinois Fair, and we trust that this year will be no exception. All who can possibly arrange to do so, should begin to plan to make an exhibit. The State Fair will be held at Springfield Sept. 30 to Oct. 5.

**Hot Weather for Honey.—**Editor Root says that in the Salt River valley, Arizona, the bee-keepers want the heat to be from 95 to 110 in the shade to get the best results in honey storing. When the temperature is below 90 there is quite a perceptible decrease in the inflow of honey. "Apparently," he says, "the Arizonians want more heat than we of the North. Yet this year’s hot weather, and the hottest nights, seem to be the best in the North for a big flow."
Storing Comb Honey and Surplus Combs.

BY G. M. DOOLITTLE.

A CORRESPONDENT wishes me to tell, through the American Bee Journal, how I would fix for storing comb honey and surplus combs in some building already on a new place he has just moved to, where this equipment is necessary. As I quite frequently have this question or similar ones asked, I will gladly comply with the request.

For a honey-room the first thing necessary to know is that there is a good foundation under that part selected for the room, and sleepers of suitable strength, so that when we happen to place several tons therein, there will be no danger from breaking down. Knowing this, the next thing is to make the room mouse-proof. This I would have cost me $200. I had to tell the owner of the very inch of it with tin, for the filth from vermin about honey is not to be tolerated at all. Having the room mouse-proof, all that is necessary afterward is to be sure the door is kept shut when not in use.

It is not to be expected this room in the southwest corner of the building, and paint the outside of the two walls which come next to it, black, or some very dark color, so that the rays of the sun may be so absorbed as to heat the honey-room as much as possible, as the hotter and dryer it is when off the hive, the better it will ripen and keep afterward.

The door to the room should be on the side next the general entrance to the building, so as to save as much travel and lugging as possible. Then there should be two windows in the room, one on the south and one on the north, which are to be opened on warm, dry days, so as to ventilate thoroughly the room and pile of honey. Over these windows, on the outside, is to be placed wire-cloth, so their efforts being directed toward the open windows, where the fresh scent of the honey comes, and, by so fixing, your room is kept clear of bees, flies, and other insects all the while.

In hanging the door for this honey-room, do not make the mistake that some do, of having it swing into the honey-room, for if you do you will regret it some year when you have a bountiful crop of honey, as it will be greatly in the way at such times, and more or less at all times. Let it swing out into the main building, and hang it so that when you wish, it will swing clear against the side of the room, thus being entirely out of the way.

On either side of the room fix a platform for the section honey, which should be at least six inches above the floor. This platform should be built nearly as solid as the floor has been, and should be so arranged that the air can circulate up between and around each section or tier of sections. Or if you store the honey away in the supers, then, no matter what style of super you may use, this platform is to be so arranged, that each super is separated from its neighbor an inch or so at the bottom, top, and all around, so that the air can circulate through and all about the honey. In cutting this out, leave as little wax as possible, for it costs little more to have it so your crop is always growing better, instead of becoming of less value, and after once fixed, the labor required for universally sending off a good article is not so great as it is to fix up that which has partly spoiled after its production.

Then you wish your honey stored and piled as above, so that the fumes of burning sulphur, or something of a similar nature, can penetrate the whole pile, should it be necessary. The greater the distance on the top of your frame is long, using as many of these as you think you will ever have use for. Now nail strips of stuff, 2½ feet long by five inches wide to theseصدي، لتسمح لهم أن يسوخوا في داخل هذه الديون. Let the distance between each strip form one to two inches greater than the depth of your frame, so as to give sufficient room to manipulate the frames handily. Three inches from the ends of these strips run a partition clear across the space, to separate them from one another, and from the other side, two combs, which partition is to have close-fitting narrow doors placed in it, spaced so as to be most convenient. Close up the ends, and see that top, bottom, and sides are as tight as possible, so that in fumigating there shall be as little waste of the gases as may be.

Now hang in the combs whenever you have any not occupied by the bees from any reason, and see that all have this use, and then let the bees rove afterward somewhere else. As often as any signs of worms are found, put in a pot of burning sulphur, close the doors, and the work is done.

Is a $200 Queen a Fake?—Queen Values.

BY DR. C. C. MILLER.

On page 391, G. M. Doolittle has gone beyond anything I have seen in print in showing that there may be justifiable confidence in placing a queen in a box, no matter where she was obtained. Granting his premises, the 10 pounds of honey and the 4,000 queens, it is hard to get away from his conclusion that we have $3,750 as the worth of that queen.

Coupled with that is a repetition of the strong intimation in page 392 that a queen in business when they advertise that they have a $200 queen. Mr. Doolittle refers to it as being like the work of a fakir, and says a fakir is a "street vender." Looking at the dictionary I find that a faké-r or a street vender and a faké-r is "one who originates a fake, humbug, or swindling contrivance." Mr. Doolittle's line of argument is somewhat hazy, but clearly discernible through the haze is the intimation of dishonesty on the part of the A. I. Root Co., for it says, "There is no value in a dollar. If that be true, then there is no value in $200, and he should hardly find fault with attaching to a queen a price of "no value," but he seems to object to a queen "having only a dollar-and-cent value attached to her," and says, "the simple saying that this queen is worth $200 without any qualification... expresses no value, save that which comes from the wear and tear of the lungs doing the hawking." Elsewhere he says, "But not to appear as a fakir, we should know that the queen has real value in the work accomplished by her bees and those from her queen daughters, putting that work out to the world as her real worth, rather than saying the value is merely a dollar or a dollar and a half.

It is not entirely clear just what it is to which Mr. Doolittle is making objection, but it sounds a little as if he were objecting to placing upon an article a value in dollars and cents. Surely he can hardly object to a thing which is already in the public eye necessary to the transaction of business without which the wheels of commerce would stand still. Mr. Doolittle himself puts a dollar-and-cent price on the queens he sends out. O. L. Hershiser told me he got a queen for $50 from Mr. Doolittle, and he told me she was worth $50 to a breeder. What wrong was there in that? The dollar is the unit of value, and there is no other way by which he could in so few words express the value he placed upon that queen than to say how many dollars she was worth. And if it was right for him to say she was worth $50 because her progeny were beautiful (I saw them, and they were beauties), is it wrong to say another queen is worth $250 if she really possesses such value? Again, on page 580 of the American Bee Journal, H. G. Omolad advertises a golden Breeder from Doolittle, saying that Doolittle says, "If there is a breeder of golden bees in the U. S. worth $100,
this one is worth that sum." Notwithstanding the condition attached, there is the value "at so many dollars." There seems no impropriety in the universal custom of naming values in dollars and cents, the only question being whether the article is to be sold at the price named. The fact that some one else may lyingly say he has a queen worth $1000 when she is not worth one-tenth of that sum, although it may have some bearing upon the policy of the case, has none upon its honesty. And it is the honesty rather than the supremacy of the A. J. Root Co. against which Mr. Doolittle is training his guns.

If he thinks $300 is too large a valuation for the queen in question, he has a right to say so, and to show cause why it is not so. The present valuation appears to be based upon length of tongue and increased harvests. Taking Mr. Doolittle's figures and using a simple proportion, we have $3,750 is to $200 as 10 pounds is to 85; ounces. So according to his valuation, one queen is worth $3,750, but the queen in question, and one out of four of them makes an increase of a little more than half a pound in the annual harvest, then $300 is none too high a valuation to place upon such a queen. McHenry Co., Ill.

Co-operation—What it Has Accomplished for Our Bee-Keepers.

Read at the Longmont meeting of the Colorado State Bee-Keepers Association, April 30, 1901.

BY W. L. PORTER.

I PRESUME there are few bee-keepers present who have not been thinking of a plan by which we may sell our honey and buy our supplies in a co-operative way. The fact that we are so far from markets in the East, where our honey is to be sold, makes it necessary that we should sell our honey in a combined way. Freights are so high that we must ship our honey in car-load lots.

Over two years ago the State Association called a special session of the membership for the purpose of organizing a co-operative association. On investigation it was found that, to do business under the statutes of Colorado, it was necessary to form a stock company. Hence the bee-keepers organized a limited partnership with a stock company with a capital of $10,000, a share being $200. It was stated that we should call this the "Colorado Honey-Producers' Association." A constitution and by-laws were adopted and the Association was incorporated in January, 1899.

Before co-operation was entered into, the tendency was for the price of honey to be lower each year. For ten years I have noticed this to be the case, so that in 1897 I was compelled to sell my crop of fine honey at $1.70 for 24 pound cases. At this time the Denver Bee-Keepers' Association decided that something must be done to better this condition. We advanced a small sum of money and one of our number opened a correspondence with parties in the East. At the same time we pledged our honey, provided we could get the best price for it, to the credit of the stock company, and pay cash on delivery, if satisfactory. We were successful in getting buyers to come on and we sold our honey in the far East at better prices than we could otherwise have realized.

The Colorado Honey-Producers' Association, upon opening for business, found it a difficult task to get the honey together, as it was very much scattered through the country. We have one or two places with a warehouse, and a room was rented. The first year, the manager was at the wareroom two days in a week to receive the honey, and it was brought and placed on deposit, a receipt being issued for the same, and the honey was kept fully insured. There was some opposition from the commission houses, as they thought we would have all the honey-business and leave them out. But at present they are very friendly, as they say the price of honey is more stable since we have organized the company, and a chance to make a steady profit. They have found it a convenience: when they have a shipping order to fill, they know where they can get the honey to fill it, and can see the honey delivered, and get just what they want.

At this point I wish to make it clear that none of the bee-keepers understand that it would be to their advantage to sell through the Association. They were also skeptical as to receiving any rebate.

Perhaps it would be well for me to explain here that at the first meeting of the Association, it was voted that one-half of the dividend should go to the stockholders, and the other half to be divided pro rata per case of honey. This was found to be an unjust division as some of the stockholders did not sell any honey through the Association. Yet when the adjustment was made the man who had a ten-dollar share got $8.50 dividend. So at the annual meeting, 1900, the by-laws were changed so that Sec. 10 reads:

"Any surplus money accruing and above the expenses of the Association shall be divided as follows:

1. A dividend of one-dollars shall be paid on each share of stock issued.

2. The balance of any surplus money remaining after said dividend has been declared shall be returned to the stockholders in proportion to the amount of commission paid them by the Association during the year, said dividends to be paid and returned to the stockholders previous to August 1 of the year in which surplus accrues."

As you will see by this plan, it is to the stockholder's interest to sell as much of his honey crop through the Association as possible, as by so doing it would not only increase the volume of the business, but also increase the price paid to him. At the close of the meeting we were authorized to raise the price paid for as much silver as we have been able to obtain in a miner's place where it was always on display, insurance was carried on the honey while in storage, and the honey was sold and loaded on the cars, the money collected for it, and all of this was done at an expense of only $5 per carload in the way of transportation to the stockholders. This proved a very satisfactory to the members. It was also satisfactory to the buyers, as it is better for them to have the honey stored where it can be displayed and they can see it before buying. It saves them five or six months in getting to the market to buy the honey, and when the honey is stored at the railroad, it can be easily loaded at short notice.

The producer is benefited in another way. When a buyer comes here he is at an expense of at least $10 per day, and that must be paid by the producer. Our difficulties have not been with competitors or in finding market for honey, but to inspire faith in the doubting bee-keeper. Instead of its being hard to find a market for the honey, it has been hard to get the honey to fill the demand created. But the two years' business has given us confidence. I don't think any man who has given his patronage, that would wish to sell outside another year. Of course we must take into consideration that last year was very favorable for us. Honey was scarce in most sections, and we most of the time we were able to sell at the open percent commission to run the business. But should we have an unfavorable year, there are still great advantages in associated work. Buyers, when honey is cheap and plenty East, will not come here as they did last year and we can take our honey East and lay it down in the market at whatever price the producer is receiving. We are on an equality with him, and the rare excellence of our honey is in our favor.

I have now given you a brief history of the workings of the Colorado Honey-Producers Association. I wish now to point out the results of co-operation, and the obstacles in the way. As to the possibilities, I believe we can find a market through the Association for all honey except that which is required to fill our local demands. Each bee-keeper should try to encourage his consumer, and sell as much in this way as he can, at the same time holding up the market. After that is done, he can market his remaining crop through the Association cheaper than he can do it himself. This has been my experience in the past few years. It took a good deal of time to deliver in small lots to my customers, and very often I had to stop in the midst of urgent business to deliver a single case of honey. This is just what we have now done through the Association, and receive a better price. This can be true of every bee-keeper in the State. To illustrate this I wish to give you an example: Lately, a bee-keeper in a remote place, wrote us that he had a large amount of comb honey. He had sent agents to Denver several times, and they could not place the honey. He finally put it in our hands. By the time the honey reached Denver, it was sold in the East at good figures, and the draft was at the bank in Denver to pay for it. I consider quick work.

I wish now to point out some of the difficulties: It costs money to do this work. To go into the office you will see on file hundreds of letters that have been promptly answered, telegrams and correspondence that have been expensive. We issue, also, a crop report. We receive bulletins, posting us on the crop of honey from Colorado, Utah and Arizona. This report is paid for. Money, money, is what it takes to carry on business. We
seem to have some members who do not understand this, and more that are not members that don't understand it. They come to us like this: What are the prospects for honey this year, and what is the condition of the market? I answer, "Well, we have the hives, and the bees, and as I have described you, I wish to sell my honey myself. I don't wish to undersell you. What price shall I hold at?" All this information he comes for has cost the Association hard money. But he goes away without offering even to consider the cooperation a success, all must co-operate, otherwise there is friction. To have a successful, intelligent and just co-operation throughout the State, there should be a certain other plan in the larger districts, and the Association should take and place for storage and should send a printed notice to each member, saying on what day or days of the week he will receive the honey. Then on the designated days (say Friday and Saturday) he can come there and take the honey. One day in the week will make the expense light, and in small towns storage can be rented quite cheaply.

When the honey is ready he should see to loading the car and billing it out. All this to be done under instructions from the general manager. This expense of rent, salary, insurance and of loading should be paid from the general office.

The expense of all points in Eastern Colorado is the same, hence all will pay to the central office the same per cent for selling the honey. That is, the general office pays all expense for storage, salary, etc., and the producers in all parts of the State pay the same for handling. To be sure to have all expense paid, we will say we make the commission ten percent. Then at the annual meeting in January, we have the business summed up and a rebate declared to each member, proportioned according to commission he has paid. The local associations of such members as have a local association only have a part of a car it can be loaded and shipped to the association in the next town. In such a case, there is a charge of five dollars for switching the part to the next association, but has only part of a car, and in case each town has only a part of a car this expense should be borne equally by them.

Co-operation carried on in this way will enable the general manager to do all the corresponding with parties East, and perhaps sending a few telegrams. Unless there is harmony among the local associations, as I have described, there must be friction, the same as we had when selling as individuals. Buyers will take advantage of this and we lose the good that should come through co-operation.

So far, I have not touched on the supply business. This can be managed the same as the honey. If local points wish part of a car, they can have the car so loaded at the central office. On the part can be loaded and part at another, and pay a little extra to have the car moved to the next point, and parties at this point should pay the extra charge. I would also suggest that the local managers be directors and should meet in conjunction with the board of directors, elected by the Association. The membership fee of the local association should be the same—ten dollars. This should go to the State Honey-Producers Association. A point would be known by letter, as for an illustration, Longmont, Division A, and next locality that organizes, Division B. Such an organization throughout Colorado will enable us to do business in a very intelligent way. The expense for negotiating the sale, the local manager can call on himself and do for very little more than for a part of the crop. The price can be maintained because we are not selling against each other. The larger we can make our Association, the more widely will our influence be felt throughout the country.

We soon would be a concern that would be known by every buyer throughout the land. We would be a powerful factor in selling honey in our own State, as we would have strength enough to push our products into the most remote parts of the country. We would sell them, as they are, in the same district. The local association can be managed the same as for a local brand, which, when established, would be always called for, as people would know exactly what to order, and would know that the honey would be the same each time.

The market that we are to be is one that will be patronized by all. It is surely true that an organization of this kind will benefit every bee-keeper that produces a pound of honey to sell, whether he supports the organization or not.

No. 7.--Practical Lessons for Beginners in Bee-Culture.

By J. D. Gehring.

(Continued from page 48.)

Mr. BOND drove into our yard the next morning while we were yet at the breakfast table, and proceeded to unhitch his team without waiting for an invitation. Hastily excusing myself to my family, I went out and accompanied him to the watering-trough, about 50 feet distant from his wagon. As he came to meet me he began the following explanation:

"I'm on hand earlier than you expected, you see. Well, when I got home last night and explained things about my plan, which I tied up in a sheet to the bees in the hive, and Harry had done some bee-business, too. 'The little fellow,' she said, while playing in the grove, found a large swarm of bees hanging to a limb of a small tree: and we hived it.' Well, when I went to look at it, the idea came into my head like a flash, that the best thing for me to do with that swarm would be to bring it along with me this morning and get you to put it into one of your hives. This I could take it back home with me in the evening. There it is," he concluded, pointing to the wagon. "I tied it up in a sheet to keep the bees in the hive. But some of them got out in spite of my precaution.

"I expected they would attack me and the horses, but they didn't; they were marvellous kind. The hive, and somehow managed to keep up with the wagon till I got here. But, you see, more and more kept coming out. That's the reason why I was in such a hurry to get the horses unhitched."

"That's a new idea of yours, Mr. Bond," I replied.

"But I'm thinking that the scheme will not work out as you have planned, because I have an idea of my own about it: I'll furnish the hive and tell you what to do, but I shall expect you to do the rest. This I could take it back home with me in the evening, however, it will be proper to put your horses in the stable, for the job will have to be done right here; or near by, at any rate.

"Yes, you see, Mr. Bond," I continued, seeing by a look in his face that he did not approve of my plan, "if we carry that bundle of yours over to the apiary and you do the transferring there, all these bees here that are flying around where they know the hive to be, will be lost to the swarm, because bee can't make them follow you if you can't afford, for, as you see, there are now several thousand outside, and more coming out all the time. There is no help for it, that I see, and no time to be thrown away in discussing the question. Therefore, while I go and get a hive, and my smoker, and a bee-veil for you, you hurry those horses into the stable. I'll be back inside of five minutes."

"Well, to tell the story as briefly as possible, inside of 30 minutes Mr. Bond's bees were contentedly humming within and near one of my 10-frame hives. Quite naturally he regarded those flying bees as very dangerous enemies, but I explained to him that bees thus situated never, or seldom, attack any one.

After carefully adjusting his bee-veil I assisted Mr. Bond in lifting his unique bundle out of the wagon, and together we carried it to a shady corner of the barn-yard, where I had placed my hive. Soon the sky began to show now that I was giving my instructions—until the corners of the sheet and laid, the ends out flat, one end toward the new hive and as close as possible up to the bee-entrance. Then he tipped the box over and carefully held it in place, side, with the open end, bottom, toward and near to the bee-entrance of the new hive. In the top-end of the box-hive had been bored two one-inch holes for bee-escapes, which were plugged. Wilddriving these plugs Mr. Bond began blowing smoke
into the hive, thus driving the bees out and toward the receiving-hive.

One thing, however, I did to assist Mr. Bond: With a small copper scoop, such as grocers use in handling teas, which I had brought from the house with me. I took a few bees from the body of the box-hive to the new hive, putting two scoop-fulls in among the frames. This established bee-connection between the two hives; and the bees were not slow in seeing it.

I remember, however, that I did not forget to direct my pupil's attention to the fact that there was only one right way to use that scoop without irritating the bees and killing many of them.

I wouldn't do all to scoop up bees as you would potatoes," I explained to Mr. Bond. "It has to be done in such a gentle, careful, and yet quick way, that the bees will not find out they are being scooped.

"And if you—" Mr. Bond said. "And if most of the bees had been driven out of his hive, there are quite a lot of bees inside that box of yours yet, and the best way to get them out and into the new hive is to tip your box bottom-side up.

They will soon all be on the wing, unless the queen is yet with them—that, however, is not probable. In a few minutes you will see that these, and the bees flying about where the wagon stands, will have united, and gradually all of them will go in where the queen is with the swarm.

But this evening you can take them home with you safely and in good shape; but not done up in a sheet, Mr. Bond. I'll show you a better way."

"What do you do that for?" asked Mr. Bond, when he saw me set a piece of board slantingly against the front of the new hive.

"I do that," I replied, "in order that the bees that fly out will mark the location of the hive before leaving it. It is not necessary to do this when a swarm is first hived. Being else, a hive of bees is moved from one location to another, or a colony is transferred from one hive to another and the location changed, it is always best to take this precaution; because without it many of the worker-bees will never be able to find their way back to it. I have after leaving it from a location they have never marked.

"Well, Mr. Bond, you have had a very important practical lesson in bee-keeping this morning; and without getting any stings, I believe. We are now ready for something else. I hope you will learn about drones to-day. I presume you remember what I said yesterday about looking after drone-brood in the parent hive of that swarm we hived. Well, that's where you will get your next lesson.

"Here you see the lesson that's before you now." I said to Mr. Bond, as he was getting to the super behind the frame of the old hive, after I had removed the cover."

"That super has to be removed before we can properly proceed with our drone-lesson. That is plainly apparent to both of us. Here you see the drone-brood, and if you learn one of the important lessons in bee-keeping. It is something that can't be avoided without detriment either by the great or small bee-keeper. If you should conclude to remove the weight of it, or put upon it surplus honey, let me help you learn how to do it. It is not a pleasant lesson, but that which is necessary in the hive."

"All right, I'm ready!" exclaimed Mr. Bond, enthusiastically. "What shall I do first? Smoke into the hive to make them still?"

"No," I replied, "the bees in this hive are nearly all baby-bees and don't require heroic treatment. The first thing is, to pry the frames loose from the super with this chisel. This will make a rush toward the drone, but give them a little smoke. They are rather timid, and easily subdued.

Then you lift the super off and set it down on top of the other. Remember to put it on with the bottom of the super upward."

"But in setting it down please be careful that none of the bees on the under side are crushed. That can be avoided by setting the super down rather slowly, and moving it carefully as you give the little things time to get out of the way.

"Be careful now, Mr. Bond." I cautioned, when he bent down to lift the super. "Make sure that you get a good hold at each end before you lift it; because if your hold slips, you may have another fracas with my bees, worse than the first."

"I thought you said, just a minute ago, that baby-bees wouldn't sting," remarked Mr. Bond, looking up, his eyes twinkling mischievously.

"I beg your pardon, Mr. Bond; but I did not say that, exactly. Such an event as your dropping that super was not then thought of. I think there are lots of bees in that super, and in the hive, too, that are old enough to sting if you hurt them and smash their treasures." "Besides that, Mr. Bond, I wish to impress this upon your mind to serve you in the future as a bee-keeper: Bees rank very high in the insect world; in the degree of intelligence they possess. I have always been guided by that idea—which to me is a fact—in any manner of managing my bees. I believe that bees—young bees—can be spoiled for life after ill-treatment; about as babies in general are prepared for the world at the beginning almost as soon as they are born. Now, right here we have a good illustration, which I shall use in order to fix the principle of the matter upon your mind.

(To be continued.)

Questions and Answers

Conducted by DR. O. C. MILLER, Marion, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail—EDITOR.]

Swarming-Time Troubles.

What is the matter with me or my bees? I have had eleven swarms and have but two left. They all settled in the best possible case and the swarms which have come out again the same day, and others the next day. Some I put in the third time and then they went away. I clipped the wings of one queen, and still they went away and got her.

My hives are of my own make—Langstroth size, made of white pine with white poplar frames, and foundation starters.

ILLINOIS.

ANSWER. I don't know what is the trouble, but can make a pretty safe guess. The great probability is that your bees would not stay in the hive because it was too hot for them. A cool, shady place for the swarm will help matters. Even in a dense shade it may be so close, with so little chance for a breeze, that I have known combs to melt down in a hive where the sun never shone. On a very hot day, after a swarm is hived, it helps to cool them off to sprinkle well the hive with water. Perhaps more than anything else it is important to see that there is abundant ventilation in the hive. Raise the hive on blocks half an inch to an inch, and at least for a day or two leave the cover partly open, so the air can pass readily through the hive from bottom to top. If the hive must be out in the sun, provide shade for it in some way. Boards laid across the top and front will do it. Give an inch or two of a regular shade-board. An armful of long grass laid on top, held down by two or three sticks of firewood, will answer a good purpose. Some give a frame of brood to a swarm. They are not so likely to desert brood.

I can hardly think the bees absconded without that clipped queen, or some other queen. They may have gone back to their old hive; they may have gone into another hive; or they may have gone off with a young queen which joined them.

A Half-Dozen Questions.

1. How do you separate the honey from the comb in old combs, without an extractor?

2. What is a Van Deusen wax-tube? What is it like, and used for?

3. How do you fasten foundation in shallow extracting frames, 5x18 inches with a groove in the middle of the top-bar, and how do you use wax and rosin in fastening foundation?

4. There was an article in the American Bee Journal of June 6, by F. Greiner, on the management of out-apiaries, where he furnishes them a new hive with six Langstroth frames, with starters. (The supers, he says, should be put over an excluder, which, however, may be taken off after a week's time.) What is the super for? I suppose it has been on the hive and he is putting it back.

5. I have some Langstroth frames with thick top-bars,
and grooved for wedges. When the wedges are taken out, doesn't the partition come out and make the frames of no account? It looked that way to me.

Answers.—1. I don't know of any satisfactory way except to let the bees empty out the honey. Of course, you can melt the whole business, but you will not get a nice article of honey.

2. One of the bee-supply catalogues, says of the Van Deurst hive: This is a very convenient tool for fastening foundation by the melted-wax plan. It is a tin tube for holding and running out melted wax.

3. Slip the edge of the foundation into the groove, then run melted wax along, or drop a few drops at intervals. Anodiftung of bees, packing, and put the string down into the hive beside the foundation. You can use wax and rosin half and half, but it is much better to use pure wax. Years ago I used wax and resin, and when I wanted to melt up an old comb I had to throw away the upper part, for I didn't want wax mixed with resin.

4. The super is for the bees to store surplus in. The excluder is to keep the queens from going up into the super. After the brood-nest is established in the lower story the excluder can be taken away, but of course the supers remain.

5. I don't see why the partition should come out when the wedge is taken out, and I don't see that it would matter much if it did. What do you want to take the wedge out for? The comb is to be built by the bees and last a lifetime. If the time should ever come that you would want to replace the comb with foundation, I think you would want a new frame, too, I have had comb that had been melted from the frame, and I have put old combs into new frames, but I don't remember ever putting foundation into old frames.

6. I think they are not liked as well as formerly. For my own use I much prefer no bevel.

**Newly-Hived Swarms Deserving.**

I have had two large swarms. Of the first one I put some comb in the frames before I hived it, and a couple of hours afterward they left. On examination I found the comb had broken from its fastenings, and lay in the bottom of the hive. The second I let go a week before disturbing, and then only to straighten the comb, of which there was a large quantity partly filled with brood and honey. Two days afterward they left the hive; after settling in the new hive, and they are apparently contented. On examining the hives, I saw that they had broken down—a piece about six inches square. The weather is warm. Do you think it the right thing to work with them in hot weather? The hive they left had a double handful of bees, packing, which are coming in. Would they develop a queen? I have no frame of bees to give them.

**Indian.**

Answer.—There is very little for doubt that there was no trouble except that the hive was insufferably hot. At all times it is important that a newly-hived swarm shall be kept cool and well ventilated, but the remarkably hot spell that occurred at the time you mention made it especially emphatic. Ordinarily a swarm is safe to remain after the queen has begun laying, but in such exceptionally hot weather results of breaking down may be sufficient to drive the bees out of a hive in which even a good start has been made. The breaking down of that comb did not drive the bees out of the hive, but the heat was made noticeable for the comb to break down was what did the business.

Yes, a double handful of bees may rear a queen if they have eggs or larvae less than three days old, but it is not likely to be a very good queen reared by so small a number of bees. It is, however, possible for brood to be kept in such scorching weather than one reared by the same number of bees in cooler weather.

As to its being right to work with bees in hot weather, if there is anything to be done with them the hotter the better so far as the bees are concerned. The only thing against the hot weather is the discomfort of the bee-keeper. As I write this the thermometer stands 99 degrees in the shade with a chance that it may be higher later in the day, and I am eager to get out to work at the bees. But that does not say that the bees should be kept as hot as possible in their hives. Raise the hives half an inch to an inch from the bottom-board by putting a block under each corner. It may be well to raise a hive still higher when a swarm is hived, and the cover may be left partly off for two or three days, so that a draft of air can pass directly through the hive. Sprinkling the hive with cold water will bring temporary relief. In the case of a swarm which left the hive after occupying it a week, the probability is that there would have been no such desertion if the weather had been normal, or if you had raised the hive.

---

**The Afterthought.**

The "Old Reliable" seen through New and Unreliable Glasses.

By E. E. Hasty, Sta. B Rural, Toledo, O.

MR. DONALDSON'S SWARM-CATCHERS.

Nice-looking swarm-catchers for a nice-looking apiary, and a nice report Mr. Donaldson makes of their success. Pages 305, 512. Other swarm-catchers of the same patent have been known to me for years—very much the same. The sound less than thunder, and no sight less flamboyant than a regiment of soldiers marching close by, would be altogether sure of attention.

WATER, POLLEN, AND HONEY.

Man's mouth calls for two indispensables—food and drink; and therefore he easily forgets that the bee's mouth calls for three indispensable—water, pollen, and honey. It appears that when he supplies the two former abundantly, and they can not find the latter in the fields, nuclei swarm out at a terrible rate, and he, perchance, scratches his head and can't imagine what's up. Page 315.

THAT PROPOLIS CHAP.

Aha! That chap offered 25 cents a pound for propolis because he didn't intend to use it. Would you believe the price high to get many offers; and figured (correctly) that some of them would consent to the bargain of pay on delivery. Page 322.

NATIVE BEEDEES NOT ALWAYS BEST.

The maxins that the native breeds of a country are the most fit for that country (as per page 323) is liable to some very heavy discounts. That which is the most fit to run wild is also not the most valuable for commerce. Again, aboriginal fitness is often only the lack of severe competition. Most countries have their native rats; but they all have to yield to the Norwey rat when he comes around. Most countries have the pirate who does not hold his own; but they all have to yield to the English sparrow when he comes around. South America has a great many species of honey-storing bees (Meliponas, Trizonas, etc.), but they will doubtless yield the ground, to a great extent, to the foreign bee with which we are familiar. The same may apply to breed as well as to species. Had South America a breed of Apis mellifera it might be nearly on a level with the Meliponas and Trizonas, and much inferior, even on its own soil, to the foreigner.

**Comments on Dr. McLane's Suggestions.**

I incline to tell the doctor (Dr. McLane, page 324) that if he mixes a pound of honey with a quart of water it will be likely to get spoiled long before a family will take it up a spoonful at a dose. Say one-fourth of the quantities. Canton flower to hold honey on the skin for medicinal objects, eh? Thanks. But when honey is used for stings it will hardly do to have it in the nap of flannel, as the main object then is to keep the pores of the skin from letting in air.

**Mr. Doolittle and Our Country.**

Anent Mr. Doolittle's lost $1,400,000,000. I'm glad the old motto has been amended. It used to be, "Figures can not lie." Now it reads, "Figures seldom do anything else but lie." Not quite sure we need the amendment this time. Thousands go pleasures in Europe with full pockets and come home with empty pockets. Millions of cash have been sent here for investment, won large profits, and then went home, and all. Many millions every year are sent abroad as interest on all sorts of bonds and things—and that's the last of those millions. Once in awhile a rich American (Waldorf Astor fashion) expatriates himself, millions and all,
The Home Circle.

Conducted by Prof. A. J. Cook, Claremont, Cal.

The Kalamazoo of California.

I have spent Sunday in the Kalamazoo of Southern California. Some one will say Pasadena, but it is not. It is even more to my mind than is lovely Pasadena. It is none other than

BEAUTIFUL REDLANDS.

As we look up from San Bernardino to the East the Sierra Madre Mountains form a U, and the incomparable city of Redlands nestles right in the bend of the arch. San Bernardino Mountain, "Old Gray Back," the highest mountain of Southern California, ever stands close by, and ever looks down in kindly manner on the valley. The Smiley brothers—Alfred II. and Albert K.—visited this place years ago, and sighted a thin, barren hill rising high up on the southwest of the town, and overlooking a deep pass to the south, through which the Southern Pacific Railroad trends as it stretches eastward between the two great peaks, San Bernardino and San Jacinto.

These great-hearted and far-seeing brothers, whom to know is to love, at one saw the possibilities of what are now famous and successful places. They purchased the barren hill-site, carried thither brains, taste, water, cultivation, and all kinds of beautiful plants, and to-day those old, barren hill-sides are transformed into marvels of beauty. To stand on "Smiley Heights" upon those magnificent grounds is to have a wealth of beautiful and thriving orange orchards known to the world, is to view a scene of incomparable beauty.

I hardly need to say that all Redlanders take pains in adorning their home grounds, and homes. All this touches the refinement and sweetness of the life and heart. I have been privileged to look in upon those homes, and share their hospitality. Theirs are such homes, and theirs such home-circles, as taste and beauty must ever fashion. Oh, that there were more Smileys to set the pace, and more laymen to follow in their wake, that we might have more of beauty and loveliness about our homes; that we might have more of cheer and beauty about us. I think the world of those have grown upon the lovely homes often almost hidden amidst the most beautiful and thriving orange orchards known to the world, is to view a scene of incomparable beauty.

I hope to visit the lovely city of Redlands and to be privileged to see for myself when and if the "Hymn of the Bees in the Apple-Tree Bloom" comes out. If you can not get your hands upon a second-hand copy of our Wood Binder, or hear me whistle jubilantly as I cut the great fleshly stems, that seem to regard Jonathan's goody as they stretch up in a night. I commiserate the home that has not its asparagus garden.

Asparagus.

I sometimes wonder if the peas are jealous as they see me look so eagerly out for the asparagus plants, or hear me whistle jubilantly as I cut the great fleshly stems, that seem to rival Jonathan's goody as they stretch up in a night. I commiserate the home that has not its asparagus garden.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of $1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it.

"The Hymn of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugenio Secor, and music by Dr. Miller. It is the only song some be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hymn." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one year's yearly subscription to the American Bee Journal at $1.00.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get our Journal and who may be some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hymn." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one year's yearly subscription to the American Bee Journal at $1.00.

Oftener still, a rich American sends millions to a worthless foreign count—and thus, in a daughter hands them small furnishings. If we could let this together without any rebate we should get quite a total, sure enough. Glad we have a country big enough to stand it all—stand it all as ox in pasture stands the loss of blood the flies take—stand it all and, indeed, and, perhaps, profit. And sometimes a major instead of a minor among the parts of speech. Page 306.
To Our Shippers.

About May 1st last, we removed our business from the buildings 120-122 W. Broadway to larger and more commodious quarters at Nos. 265-267 Greenwich St., and 82, 84, 86 Murray St., and we duly sent to our friends in the trade a notice of our removal. Shortly after we vacated the premises (120-122 W. Broadway,) one Joseph M. McCaul, rented a portion of our old quarters, and hung out a sign, "Hildreth, McCaul Co., Jos. M. McCaul, Prop.," with other large signs to the effect that his business is "headquarters for honey, beeswax, maple sugar and maple syrup."

The mercantile agencies report that Jos. M. McCaul is the sole proprietor of the new business, and that he claims to have paid to one Henry P. Hildreth (who has no connection with our business,) a consideration for the use of his name.

We will not comment upon the act of leasing our old quarters and exposing thereon the sign, "Hildreth, McCaul Co.," further than to state that we have instructed our attorneys to apply for an injunction restraining the said McCaul from using the name of "Hildreth" in connection with his business in any manner whatsoever.

We value highly the good name and business we have established by many years of satisfactory dealing with our friends in the trade, and we therefore send this notice so that you may not possibly confound us in any manner with the so-called "Hildreth, McCaul Co."

Our firm name remains as heretofore, and all our business is carried on at our new quarters—

Nos. 265-267 Greenwich Street,
and Nos. 82, 84, 86 Murray St., New York, N.Y.

Respectfully yours,

Hildreth & Segelken.

Prospects for a Large Honey-Flow.

The prospect is good for a large honey-flow this year for the following reasons: 1. It has been a warm spring; 2. The weather has been a week. Alaske and white queen are yielding well, now. Wood Co., Wis., June 29.

Jan. H. KNOTTS.

April Weather Hard on Bees.

I put 42 colonies of bees into winter quarters, and 40 of them came through safely, but one died in April of spring dwindling. April was a very hard month on bees, only 14 days out of the first 25 being sunny. On April 6 I lost my 29 colonies of bees from Bigsby to this place, and there were not 30 days in March that the bees did not go out foraging. This year there were five days in succession that no bees were flying. John T. COOK.

White Clover Dried Up.

White clover is about dried up, three weeks ahead of its usual time. Basins is just beginning. It won’t tell what will yield yet, but it looks well.

E. F. JOHNSON.

Den Co., Wis., July 1.

Finds Bee-keeping a Pleasure.

I was born in Hillsdale Co., Mich., April 16, 1889, and lived on a farm until about 18 years of age, when I began attending high school in Hillsdale. From that time until now I have been in the school system as student or teacher.

In the fall of 1906 I married Miss Mazie E. Harmon, of Mason County, Ohio, because of the lack of opportunities of school work, my health began to give way, and we decided to locate on a fruit farm. So here we are in the midst of the Persimmon and Huckleberry locality, with more than a hundred trees to look after. We have daily mail delivery, telephone connections, and are pleasantly located.

During the fall of 1896, while making a small business transaction with one of my neighbors, he proposed to turn three colonies of bees over to me in the deal. I knew nothing about bees, that is, so far as management was concerned, but I have a honey-tooth, and am somewhat curious to learn the habits of plants, insects, etc., so the deal was made. The neighbor agreed to deliver the bees and pack them for us, which he did as he agreed, but he packed them too tight.

Of course, as soon as I purchased some bees I began reading everything I could find on that subject, getting ready to manage them the next spring. Spring came, and one fine day my neighbor came to unpack the bees and get me started. As I said before, he had packed them too tight, and all were smothered. This was a blow, but the bees were dead. My neighbor was perplexed and disappointed, and of course I was. But he left me the honey, and gave me another colony in a very poor box-hive, and I began to work with my bees.

During last summer, I drained the hive, and I hired the new swarm on the old stand, and soon transferred the old colony to a movable-frame hive. I did not get much surplus last season, but bought another good colony in the fall, and

I am Now Prepared to fill orders promptly for Untested Queens reared from a breeder of the HUTCHINSON SUPERIOR STOCK, or a select GOLDEN breed of the best quality, with a charge of $25 each; $4.00 for 6, or $7.50 per dozen.

Farm Wagon Economy.

The economy of this proposition is not all found in the very moderate price of the wagon itself, but in the great amount of labor it will save you. A wagon that will carry a load of 1200 lbs. and can be drawn by one horse, will save you 1200 lbs. more than the ordinary wagon. The Electric Wheel Co. who make this Electric Handy Wagon and the now famous Electric Wheels, have solved the problem of a successful and durable low-down wagon at a reasonable price.

Write for catalog of the full "Electric" line to Electric Wheel Co., Box 10, Quincy, Ill.

Some Kinks in Bee-Keeping.

Take a piece of fine wire-cloth over the valve on the smoker bellows. This will keep other people from spoiling the spring by sticking their fingers through, as well as to serve to keep bees, etc., from getting in and preventing the valve from closing.

In wiring frames for the tack slanting, then fasten the first end of the wire to the bottom, and the last one to the top. Driving the tack draws the wire tight. The "B R C" book says, "Do not have it tight," but with an experience over 10,000 frames this season shows that the tighter the wire the more good it does.

Two horizontal wires seem to be enough even with large smokers, and except to hold the whole weight of the bees.

If one end is held against the bottom, put the spacing staples on the bottom and the end of the top by so doing one will avoid smashing bees when lifting the frames out in a hurry. This is the old method used by the Coggshall and other rapid workers. These staples should be used on all frames, either short top-bar or not. They also keep the ends from getting stuck fast at the bottom.

A pair of bicycle pants guards when at work in the apiary, and thus keep the bees from getting inside of your trousers.

Always give the visiting small boy (and the big ones, too,) a nectar and honey. When they know that they can get it by going when the owner is there, they will not visit his apiary for it when they leave. HARRY HOWE.

June 18.

Big Clover Crop—Bees Booming.

We have the biggest crop of white clover that I ever saw. Bees are booming, and I am putting on the second size. L. HIGGINS.

An Old Time Honey-Flow in Ohio.

The past spring here was a very poor one, and we have not been able to stock much of our nuclei the second time.

We are having a busy honey-flow for the first and two other districts and we speculate it very much. The prospect for its continuance is good. H. H. QUINN.

Bees, Bears and Turtles in the Mangrove Swamps.

Bees are in fair condition, but the honey season is very late here, and little honey has been stored yet.

I have moved over apriaries to the mangrove swamps, where we elevated the stands about seven feet above ground, so as to be sure they have them above water in case of a gale. I am now fixing to move 150 more colonies to one of another mangrove swamp, where there are about 140 acres of solid mangrove trees within a mile of the bees. You can imagine what a job it is to build stands seven feet above the ground for 150 colonies, and have room to work with them. Also to build a barred fire fence around that is bear tight and bull strong.

Bears are quite plentiful here. W. A. Martin and I are both of the opinion that the bears that come from Mr. Prang's home the other day, and upon investigating found two bears and bear cubs in the swamp and took the caves, that would weigh about 25 pounds each. Mr. Martin took the caves to Ft. Pierce, where he sold them for $10. He

packed them all on the summer stands for winter. Two of them came through the winter in good condition, and the other one not so good. They have warmed, and all are working well on clover now.

I consider that the knowledge gained and the pleasure derived from the bees pay well for the venture, and I expect to raise some fine honey this year, and continue to study the habits of the little bees. D. STOWELL.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with $2; or, one Tested Queen free as a premium for sending us FOUR new subscribers with $4.00).

We have arranged with one of the oldest and best queen-breeders (having many years’ experience) to rear queens for us this coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported him himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring vein or smoke. They store the clover honey last season.

All queens guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, $1.00 each; Tested, $2.00 each. Send all orders to

GEORGE W. YORK & CO. 144 & 146 Erie St., CHICAGO, ILL.

Please Mention the Bee Journal when writing to Advertisers....

Supersede and Control of Queens.
Dr. C. C. Miller says in the American Bee-
Keeper: It is undoubtedly cheaper to let the bees themselves do the superseding than to replace queens. Superseding others, either home-reared or purchased; but the wise bee-keeper will still keep the whole matter under his control by superseding all poor stock and encouraging the good. From time to time he will seek to improve by introducing fresh stock from the best breeder he can, and not at that. He will keep tab on the performance of every colony, and be able to tell you just what the progeny of each of the queens did during that season or year, and what is likely to happen to them; and knowing this, he will know from which queen he is to rear. This matter of keeping a careful record of the performances of each colony is at the foundation of building up an apiary that is to bring in the best results. Bee-keepers do not care to keep any such record:

If you have never given the matter any attention, perhaps it may be well to recall some facts that you have probably noticed without carefully considering their bearing. You may have noticed that, as a rule, the colonies most given to swarming have not been among the best for storing surplus, and that those which have made the best super records have not wasted much time in swarming. If you have paid no attention to this, but have left the bees to run their own way, the bees most given to swarming are the ones that have given you increase almost entirely.

AMERICAN BEE JOURNAL.
Langstroth on... The Honey-Bee
Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee-Journal—Chas. Dadant & Son. Each subject is clearly and thorley explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for $1.25, or club it with the American Bee Journal for one year—both for $1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with $3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.
14 & 16 Erie Street, * CHICAGO, ILL.

AMERICAN BEE JOURNAL July 11, 1901.

while your best colonies have given no increase. Don't you see that such a course, continued indefinitely, will inevitably result in ruinous bees. By keeping matters in your own control, you can make the current run the other way.

Introducing Queens With Tobacco-Smoke.

Here are instructions that I am sending out this year for introducing queens, and guaranteeing the safe introduction. After giving notice of the date when the queens will be sent, as follows:

As soon as you receive this notice, remove the queen from the colony to which you expect to introduce the new queen. When she arrives, put her away in a safe place until after sundown, just at dusk, then light your smoker, and when it is well going put in a pillow of smoking-tobacco, put on the cover, puff until you get an odor of tobacco, then puff with two good puffs into the entrance of the hive. Wait two or three minutes, then send in another good puff, remove the cover, drive the bees down with a puff of smoke, open the cage and allow the queen to run down between the combs, following her with a puff of smoke, and put on the cover. Half an hour later, light up the smoker again, putting in the tobacco as before, and blow two more good puffs in at the entrance. If no honey is coming in, feed the colony a pint of syrup each night from the inside of the hive, but don’t disturb the brood-nest for four or five days.—Bee-Keeper’s Review.

Weight of Wax-Scales.

E. F. Robinson gives this interesting bit of information in the Canadian Bee-Journal:

While making a display of the natural history of the bee a few weeks ago, I took the trouble to sort out a lot of wax-scales from some bee refuse, and arranged these natural scales, into the word WAX, but before doing so I weighed a number on a pair of jeweler’s diamond scales to find out how many went to the pound, for I could not find any reference to this in any of the many books on the bee. I find there are just 192 to the grain, and of course 1,474,560 to the pound.

Inversion of Brood-Combs.

This has been found profitable by Mr. L. L. Eshenower, of Pennsylvania. In the fall he takes away all combs not covered with bees, taking good care of them, and in the spring he returns them, against dawm. He uses an inervetible frame of his own making, and raise opens the combs of the colony when he returns them to the hive. He believes that he has prevented many cases of spring dwindling by this practice. He admits that inversion has been cast off long ago, but, very wisely, says that we sometimes cast away something that we think we have tried, whereas, we have scarcely made its acquaintance.—Bee-Keeper’s Review.

Co-operation Among Bee-Keepehrs.

The June number of the Rocky Mountain Bee Journal is almost entirely taken up with the matter of co-operation among bee-keepers. Those Coloradans are not merely theorizing on the matter, but have been putting in practice some excellent co-operative work, somewhat to the advantage of their pockets. It seems that they have so enlarged the work that they now have, under the title of “The Colorado Honey-Producers’ Association,” an office kept open in the pound in Denver by Mr. E. T. Snell, with Frank Rauchfuss as its energetic manager. The following interview with Mr. Rauchfuss is given in the paper mentioned:

1. What advantage, if any, accrues to stockholders in the Colorado Honey-Producers’ Association, besides dividends on their stock, in the purchase of supplies through that Association?

2. You should emphasize the fact that the Association was formed and is now able to send grains, and have the members, to market their honey profitably, at an advantage of price, but the price must be good, and the customers must be willing to accept a good grade of honey, and at the close of the season, be able to return them 16 percent of the usual commission. Handling only honey we could not afford to keep a store open the whole year. By expanding our business we are able to keep the store open all the year; to keep in closer touch with the bee-keepers upon the trade, and also get the best prices more successfully, because more intelligently. You know that supplies are cheaper than last year. Very little claims for pay this year. The State Association deserves part of the credit, perhaps the larger part. Any one who will look back to the record during these years can find out the advantages for himself.

3. Has the handling of supplies by the Association tended to cheapen the price of supplies in the city of Denver?

4. If you are comparing, as Mr. Rauchfuss has done, the price of supplies, abstracting the returns, they were to the advantage considerably.

5. Would you favor the establishment of branch associations for the handling of supplies, subsidiary to the main association in the smaller cities throughout the State?

6. Mr. Rauchfuss answered with an emphatic “Yes!” and then walked away to await an impatient customer.

Horehound Honey.

H. H. Hyde says in the Southland Queen that horehound is in his locality in Texas, “...and sometimes it ruins a good deal of honey in the fall, but in the spring it fortunately blossoms early enough so that all the honey is consumed in brood-rearing.”

Fastening Foundation.

C. Davenport fastens foundation in brood-frames or sections by means of something like a large medicine-dropper or pipette. He says in letters in Bee-Culture. 

Mine is made of a tin tube about 4 inches long, and not quite 1 inch in diameter. The lower end of this tube is gradually tapered down to a point, so that the extreme end is a little less in size than what it would be on an ordinary lead-penil if the lead were removed to the same size as the extreme end. A rubber nipple or ball is attached, and it is important to have this rubber fit over the tube tight enough to exclude air. When the lower end is placed in melted wax, or any other liquid, with the rubber bulb compressed between the thumb and finger, as soon as it is allowed to expand by air suction, it draws some of the liquid into the tube. By allowing the rubber to remain compressed, the tube will not leak when withdrawn, no matter what position it is held in. Pressure on the rubber forces the liquid out slow or fast, just as desired.

Does a Queen Carry Foul Brood?

The editor of the Australasian Bee-Keeper says:

Your opinion on the matter is so decided that should I need a queen from a foul-brood apiary I would introduce her into a healthy colony of bees without the slightest hesitation or fear of communicating the disease. I would, however, deal very deliberately with an apiary accommodating a case of foul brood, as one would be crushed and afterwards burnt. In my opinion, it is the bees only that communicate the disease, and not the queen. To back up my assertion, I may say I know of numerous queens from foul-brood colonies having been introduced to healthy bees, and...
have yet to find the queen blamed for communicating the disease. When I meet a queen from elsewhere, or an imported queen, I open the cage before a closed window, and after the queen is caged I destroy every bee. Most of them are readily washed when flying against the window glass.

Extracting. Supers Over Winter.

In the Southland Queen, Louis Scholl tells that he practiced putting enameled cloth over his brood-frames and pliing the extracting-supers above for winter. He says further:

But this had to be removed in the spring, last year I tried some of the heavy brown paper used by butchers, and putting it on top of the brood-frames, by just tiling back the supers and all above. If honey is in the top supers, a hole can be made in the sheet of paper to let the bees go for it. I would prefer to have the sheet of paper a little narrower than the 24" is wide inside, leaving a passageway next to the walls.

In spring, as soon as the colony gets more populous, and more room is needed, the bees will attend to the paper, gnawing it away, and saving the apiarist the labor of removing the paper.

The Emerson Binder

This Emerson stiff-boarded binder with cloth back and silver edges is cataloged in the Journal and sells for only 26 cents; or we will send it with the Bee Journal for only 30 cents. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this Emerson 8 quarto binding is necessary.

CATALOG FREE.

Bee-Supplies

1. J. STRINGHAM,
105 Park Place, NEW YORK, N.Y.

I will send Bee-Journal for 80c. Please mention the Bee Journal.

Reduced Rates to New York City.

From July 1st till further notice the Nickel Plate Road offers round trip tickets Chicago to New York City, returning in like manner, or going and returning by different routes, at option of passengers. No excess fare is charged on any of its trains. Meals served in up-to-date dining-cars, ranging in price from 25 cents up, but not exceeding $1.00 for each person served. Secure tickets and sleeping-car berths at City Ticket Office, 113 Adams St., Phone 2017 Central. 15-2A1T.

Catnip Seed Free!

We have a small quantity of Catnip Seed which we wish to offer our readers. Some consider catnip one of the greatest of honey-yielders. We will mail one ounce of the seed for sending us one ounce of the seed for sending us one new subscriber, or one ounce of the seed and the American Bee Journal one year—both for $1.30; or will mail an ounce of the seed alone for 50c. As catnip seed is very small, better order soon.

GEORGE W. YORK & CO.,
144 & 146 Erie St., CHICAGO, ILL.

Chicago, June 19.—New comb honey has not yet reached this market. It will sell at 1.50c if choice white, and the amber at 95c. The market is too large to be weathered, and we have had a few cases of a lot that we had held for us, expecting it would be needed. Advises that shipments will be sent, and that the market will be kept for the trade is being done in extracted, as large as the market will stand. A very heavy demand at low figures; some sales of amber have been made at 45c for early autumn delivery; white is held at 65c. Bee wax sells at 25c.

H. W. WERNER.

Boston, June 29.—There is practically no comb honey in the market, and the prices are very low, and will hold very little for call for it. We expect we will have a much larger supply of wax this month. Market for extracted dull, at 80c.

B. A. BURLINGTON & L.

OMAHA, May 1.—Comb honey, extra white, 2-frame cases, per case, $3.50; no. 1, 2c.; amber, $3.00. PEYTON E. BROWN.

NEW YORK, June 1.—Extracted honey is exceedingly dull and very little moving. We note for the present: White, 15c.; light amber, 59c.; Dark amber, 95c. Some demand for comb honey at uncharged prices. New crop is now being shipped, and the market is evidently at about 120c., according to quality and style. Bee wax, 2c.

HILDEBRAND & SIEGEL.

ALBANY, N. Y., June 18.—Honey market is dull and quiet. Receipts are small, and the market is likely to be held by fruit and bird exterminators. H. R. WRIGHT.

DETOUR, June 27.—Very little old honey in market, and no new honey is come in yet. Splendid showing for a good field of white clover honey. Bee wax, 2c.; demand light.

M. H. BENT & SON.

BUFFALO, June 28.—Honey not wasted till cool fall weather. Market dull, 60c.; Extracted, 80c. Extracted not wanted. Fruit takes place of honey now. BATTERSON & CO.

KANSAS CITY, June 14.—Very little old honey on our market but what is damaged by being granulated. Sales of comb honey are bound for the best grade No. 1 Colorado. Amber, 15c. Bee wax at 25c.

W. R. CROMWELL PRODUCE CO.,
Successors to C. G. CREAMER & CO.

SAN FRANCISCO, June 5.—White comb, 11% per cent; amber, 30c.; dark, 20c.; Extracted, white, 59c.; light amber, 45c.; amber, 35c. Bee wax, 260c.

Dealers are very bashful in their ideas, but are not securing much honey at the prices they name. I see a small way to special trade an advance on quotations is being realized.

Wanted

Fancy White Comb Honey inmodrip cases; also Extracted Honey. State price, delivery. We pay spot cash. PERCY & BROWN & CO., Front & Walnut Sts., Cincinnati, Ohio. Reference—German National Bank, Cincinnati.

We will pay 25c cash, per lb. for any one who will sell us 100 lbs. each of amber, 25c. per lb., and as soon as they are taken up, 25c. cash, per lb., for pure, dark beewax delivered here. We are a jobbing house. J. L. BUCKNELL, Des Moines, Iowa.

1901—Bee-Keepers’ Supplies!

We can furnish you with The A. L. Root Co.’s goods at wholesale prices. We can save you freight, and ship promptly. Market price paid for your comb honey. For descriptions and prices, send for our new catalogue.

Please mention Bee Journal when writing.
We have a Large Stock on hand and can ship promptly.

ITALIAN QUEENS, warranted
Testsed, $1.00; Untested, 75 cents, by return mail.

RIVER FOREST APIARIES
Oak Park P.O. River Forest, Cook Co., Ills.

Mention the American Bee Journal.

SWEET CLOVER
And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

\[
\begin{array}{ccc}
\text{Sweet Clover (white)} & 50c & 75c \\
\text{Alfalfa Clover} & 75c & 1.00 \\
\text{White Clover} & 75c & 1.00 \\
\text{Alfalfa Clover} & 1.40 & 3.50 \\
\text{Japanese Buckwheat} & 30c & 50c \\
\end{array}
\]

Prices subject to market changes.

Add 25 cents more for a 10-pound order, for cash, if wanted by freight, or 50 cents per pound if wanted by mail.

GEORGE W. YORK & CO.
144 & 146 Erie Street, CHICAGO, ILL.

I ARISE

To say to the readers of the Bee Journal that

DOOLITTLE...

has concluded to sell

QUEENS in their season during 1901, at the following prices:

1 Untested Queen $1.00
3 Untested Queens 1.25
1 Tested Queen ... 1.25
3 Tested Queens ... 1.75
1 selected tested queen 1.75
Select Tested Queen last year's rearing 2.50

Extra selected breeding, the very best... 5.00

Circular free, giving particulars regarding each class of Queens, conditions, etc.
Address,

G. M. DOOLITTLE,
112 A 2d
Borodino, Onondaga Co., N. Y.

Please mention Bee Journal when writing.
TELLING THE BEES.

Out of the house where the slumberer lay,
Grandfather came one summer day,
And under the pleasant orchard trees
He spake this wise to the murmuring bees:

"The clover-bloom that kissed her feet
And the posy-bed where she used to play
Have honey store, but none so sweet
As ere our little one went away.
O bees, sing soft, and bees, sing low;
For she is gone who loved you so."

A wonder fell on the listening bees.
Under those pleasant orchard trees.
And in their toil that summer day
Even their murmuring seemed to say:

"Child, O child, the grass is cool.
And the posies are waking to hear the song
Of the bird that swings by the shaded pool,
Waiting for one that tarrieth long."

"Twas so they called to the little one then.
As if to call her back again.

O gentle bees, I have come to say
That grandfather fell asleep to-day,
And we know by the smile on grandfather's face
He has found his dear one's biding place.
So, bees, sing soft, and bees, sing low.
As over the honey-field you sweep-
To the trees a-bloom and the flowers a-blow,
Sing of grandfather fast asleep;
And ever beneath these orchard trees
Find cheer and shelter, gentle bees.

—EUGENE FIELD.
**Weekly Budget.**

"My Wife came pretty near calling me honey last night."

"So I."

"Yes. She called me beeswax."

Dr. C. C. Miller, of McHenry Co., Ill., wrote us July 10:

"102 degrees in the shade to-day. I don't remember a day in the month before. Neither do I remember so dry a summer before. Much of the grass looks as dead as in winter. A very blue time for bee-keepers."

The **Australian Bee-keepers' Review** is the latest candidate for the favor of bee-keepers. Pit; that a journal so neatly gotten up could not have had a name all its own, without the danger of its getting mixed up with a very excellent bee-paper published on this side of the globe.

Mr. J. T. Hairsont, of Cherokee Nation, Ind. Ter., wrote us July 9, as follows:

"We are having the most disastrous drought and hot weather ever experienced here. Corn and hay are beyond help, bees are doing nothing, so no surplus honey." I was wounded and shot April 12, my thigh being broken, and also badly cut. I am crippled for life. Six weeks later my little girl, Jennie, had her hand crushed in a feed mill. It has been amputated.

"I have 175 colonies of bees."

Surely, Mr. Hairsont has more than his share of troubles. All our readers will sympathize with him in his many misfortunes.

Mr. George B. Whitcomb's home apary is shown on page 455. It will be observed that he has both the unpainted and the painted hives, preferring the former in an excessively wet climate. The stands used for them are the best kind for there, and he thinks the advice given that person in Multnomah County was poor, when he was told that hives on the ground or near it, and covered with straw, were all right. Mr. W. has seen the snow flat as much water there that it would fill the ground and drown the bees. In fact, a neighbor keeper, Mr. Christensen, lost 40 cold colonies just that way. Also an observatory hive containing one comb would not work there, as the nights are too cool at any time of the year.

Mr. Whitcomb had just bought the apary of Simon A. Nickerson, situated in Linn County, and spent a few days in knocking out the swarming-fence; he believed he had succeeded completely. Mr. Nickerson is one of the old subscribers to the American Bee Journal, and has been counted one of the best-beekeepers in Oregon in his time, but he has been rapidly failing for the past two years, until now his lower limbs are completely paralyzed, and he is bedfast, being fastened to the upper part of his body, with a cord suspended from the ceiling, to which a handle is fastened. This is sad indeed.

Indooping over Mr. Nickerson's apary, Mr. Whitcomb can see the history of bee-keeping for a number of years past. The majority of his colonies were in modern dovetailed hives of the s-frame and dummy-board pattern, but a few were in the old 10-frame chamfered-edge A. I. Root pattern of 15 years ago, of which there are 30 or more neatly piled up along the fence.

The solar wax-extractor is there, and so is the Parlor bee-escape; the Alley queen and drone trap, and numerous other things have been tried, but the best thing Mr. W. has seen for real, downright good service is a pair of frame tongs. They are like pliers, made just wide enough when open to slip over the top bar and hold it firmly between two lugs (one in each jaw) that are pressed into the wood when closed; while one of the jaws is longer than the other, so as to be used in prying apart supers, hive-covers, etc. In fact, he thinks it is the best tool for handling cross bees 'that he ever saw, as with it he can manipulate the frames with one hand while keeping the smoker in the other.

Mr. A. I. Root is in danger of making trouble for the government. He is not entirely satisfied with its course in the liquor problem, and he thinks the Agricultural Department might issue a bulletin about tobacco just as well as about beans, sugar, eggs, etc., giving its value as an article of steady consumption. He says in Gleanings in Bee-Culture:

"I wish I had influence enough with the Agricultural Department at Washington to induce it to publish a bulletin with a heading something like this: "Tobacco, and its General Effect on the Human Family. Should its Cultivation and Dissemination be Encouraged or Discouraged?"

Then I should like to have a closing chapter something like this:

"The Effect of Tobacco on Children and Young People. Should its Use be Prohibited to those under a certain Age? If so, what Age? Also a Consideration of the Cigarette Habit."

Robert W. Polley, of Middlesex Co. Mass., writing us June 10, said:

"I have successfully transferred, united, Italianized, and fed up weak colonies all from colonies taken from the Apiary, which is not a small one; besides wintering bees safely; and, in fact, all the good I know about bees I have studied out of that paper. It is needless to add that I am very much pleased with it."

Mr. E. F. Hasty, of Lucas Co., Ohio, wrote us July 5, as follows:

"I didn't think, with such bad wintering and bad spring, that such a rush of swarms—the greatest for some years—would ensue. I thought there would be almost no swarms at all. That's the way when we keep bees. The unexpected happens."

**Queen-Clipping Device Free....**

The **Monette Queen-Clipping Device** is a fine thing for use in catching and clipping Queen wings. We mail it for 25 cents; it will send it FREE as a premium for sending us ONE NEW SUBSCRIPTION a day to the Bee Journal for a year at $1.00; or for $1.10 we will mail the Bee Journal one year and the Clipping Device. Address GEORGE W. YORK & COMPANY, Chicago, Ill.
The Thousand Members of the National Beekeepers' Association (or the balance of about 200) which we are trying to secure among the readers of the American Bee Journal, are coming in slowly. As promised, we begin to publish this month of those that are going to help make up the number necessary to have an even 1000 by the time of the Buffalo convention in September. Since we began this effort, we have received the following names with a dollar each:

W. J. Forcheck.  C. H. Harlan.

We hope by another week to have a much larger list of names of new members to publish.

Are We Doing Our Best in Breeding?—While the theorists are having their say, and are doing some good by stirring up to a full knowledge of what is required in scientific breeding, are the rank and file of beekeepers doing their best with what they do know? It is not difficult for any one to understand that if he has a colony that gives twice as much as the average in surplus, and another that gives only half as much, if he makes his increase by swarming, and gets more swarms from the poorest than from the best, the old stock will be worth more instead of better. And yet are there not thousands who will get their increase just by allowing the bees to have control of swarming? And in that case is it not generally the case that the poorest storers do the most swarming? We can not control the matter of mating to a very great extent, but are pains taken to control it as far as possible? Are drones superceded in poor colonies and encouraged in the best? If we do the best we can with what we have and with what we know, will we not be doing a good deal better than we are now doing? These are trite words, but it is none the less important to stir up your pure minds by way of remembrance.

Bee-Keeping on Paper.—If a beekeeper is down with a fit of the blues, one way to cheer him up is to give him a good supply of reading-matter about bees, taking an average lot as found in agricultural and other papers. It is true that some agricultural papers have bee-departments that are reliable, but most of them are more or less re-liable. In the Twentieth Century Farmer is an article of some length telling about "traveling bee-colonies" owned by C. I. Graham, in California. Some of the Bees may be of interest to the readers of the American Bee Journal, who are left to separate fact from fiction.

The renascent activity of bees depends upon the coming of spring flowers, and early in the season it is easy to move them before they have aroused themselves from the winter's listlessness. When Mr. Graham moved his bees in April, it was predicted that they would desert him by the wayside, for while bees may be moved in winter, it is generally considered impossible to move them in the active season. The difficulty was solved by traveling at night. He has a wagon the size of a flat-car with crate on it holding 300 colonies. Under cover of darkness the crate is slipped from the car to the wagon, and the bees taken to some sweet bower before day-light. When the combs are full the honey is "strained."

The same paper contains an extract from the New Orleans Times, describing the Cuban bee. It says: "he is quite different from the American bee. The Cuban bee is lazy, trifling, almost slovenly, looking like a drone when compared with the American bee."

"The Cuban bee has a sort of oxcart movement when he goes about his work. The American bee is snappy, quick, and almost electrical. Now, why is this! I have my own theory, and I base it upon the best principle of science, a principle universally recognized for its potency in the shaping of character. It is a matter of environment."

"The Cuban bee has been surrounded by slow methods and awkward, crude ways of doing things. He simply reflects the life, the mannerisms and the methods about him. He is still the bee of the oxcart age, and buzzes about his business in an oxcart suit. He is a Cuban to the manor born. The American bee's industry may be accounted for in the same way. He is a natural-born hustler. He is an American, full-blooded and full-fed.

What Do We Know About Breeding?—Several writers have had considerable to say as to the ignorance of beekeepers with regard to anything like the intelligent breeding of bees. It is probably a fact that among the breeders of horses, cattle, swine, poultry, etc., there will not be found so much ignorance as to the laws of breeding as is to be found among breeders of bees. So it is well that of late years much has been said by experts of arousing attention to the subject, albeit it may be in the wish of many that more of instruction had been given by those who find fault with the lack of knowledge. To the question: "What do we know about breeding?" the plain answer probably must be, little or nothing.

After all, are beekeepers so greatly to blame for this? In intelligence they will probably rank with breeders of other classes, and other things being equal, they should know as much about the laws of breeding. But other things are not equal. The breeder of horses may make himself acquainted with the laws of breeding, and in applying those laws for best results one of his chief cares, if not his chiefest care, is to make a wise selection of the two intended parents of his future stock. Without this care in selection his efforts will count for little. In the ease of the bee-keeper such selection has been considered next to impossible of accomplishment. Of what avail to study carefully just the drone that should meet a certain queen, if the control of that drone is entirely out of the question? There is expense for the fact. If it be a fact, which is not here denied, that beekeepers know less about breeding than the breeders of any other class of stock.

At the same time it would be a gain if more were known as to the laws of breeding. Possibly we are just on the eve of entire control of fertilization, and it would be a wise thing to prepare for it in advance. Even if we have only a very limited control of the mating of queens, it will do no harm to have all the knowledge that can be used in that limited control.

Are Long Tongues of Value Per Se?—In an able article which we copy on page 453, Frederick B. Simpson says:

"To my mind the long-tongue agitation is too much like treating a symptom instead of the disease itself. I believe that long tongues are of value only in so far as they represent an increase in vigor: or, in other words, only when such increased length is the direct result of increased use of the tongue, indicating greater activity and vigor."

That might be understood as meaning that in and of itself there is no value in a long tongue, only as it is a sign of other qualities, just as there is no value in the hands of the Italian only as they are a sign of special qualities possessed by the Italian. It is doubtful that Mr. Simpson meant just this, for elsewhere he says, "Other things being equal, I want long tongues."

Given two bees exactly alike in all other respects, one having a longer tongue than the other, and there is no question that the longer tongue would have the advantage wherever there were flower-tubes a little deeper than the reach of the shorter tongue, and yet within reach of the longer tongue. At the same time it is a mistake to suppose that the length of tongue is an exact gauge of the value of two different bees. The bee with shorter tongue may have extra diligence to make up for shortness of tongue.

No. 3.—Some Reminiscences of an Old Bee-Keeper.

BY THADDEUS SMITH.

The Italian bee was introduced into this country about 1650, or soon after, by the Spaniards in the ten-frame hive. I have not the statistics or the history of either event before me to enable me to give the exact dates, and can speak only in a general way from recollection; but both came about the same time, and in so doing gave a new impulse to the bee-keeping industry, and a momentous impetus to the growth of the business in this country that the last half-century has witnessed.

Many persons engaged in other pursuits—some who had never kept bees, and others who had only a few colonies—became interested in this new and strange interest, and this interest led to an investigation, both theoretical and practical; and as this investigation proceeded some became quite fascinated with the business. The ease with which one could examine the hive, and the economy of the hive with the movable-combs, and to introduce to a colony of native bees a queen of a new race and color, and seeing the natives gradually disappearing until in a few weeks they would all be gone and the new race occupying their places, afforded means of verifying and demonstrating many interesting facts in the natural history of the bee. The short life of a worker-bee in the working season was a revelation that astonished many who always supposed bees to have a long life. The usual demonstration of this by the introduction of an Italian queen would convince the most skeptical. And so were many other facts in the history of this wonderful insect demonstrated.

This new interest in bees caused by the Italian bee, resulted in adding twenty times the number of beekeepers. Some thought they would find a pleasant and profitable occupation in producing honey on a large scale for the market, as the Italians were, by the vendors, to be greatly superior to the native honey gatherers. Others saw a prospect of gain in rearing queens for sale at prices from $5 to $20 each; and the country was soon flooded with queen-breeders until the price got down to one dollar a bee, and many of them went broke.

Manufacture of patented and non-patented hives, also sprung up all over the country. An impetus was given to every department of the business. The literary department was greatly augmented, and we had new authors of bee-books, and pamphlets numerous, and many new contributors to the bee-papers from all classes and professions, some of whom have been of great advantage and a blessing to the fraternity.

I think it can safely be said that had it not been for the Italian bee, Mr. A. I. Koot would never have gotten up that interest and sustained enthusiasm on the subject that led him to give up a pleasant and profitable occupation to go into the bee business. The following is an extract from his publication, "A B C of Bee-Culture"—"There have been so many writers of books on bee-keeping, that it is an easy matter to collect all their facts and experiences: The bee-keeping public would never have seen those wonderfully interesting and instructive letters of "Novice" printed in the early volumes of the American Bee Journal. Gleanings in Bee-Culture never would have been published; neither would the standard work "A B C of Bee-Culture"—"A B C of Bee-Culture"—have been printed; nor would those great manufacturing and industrial establishments with all their various branches and departments. In existence today—such as this moveable-comb hive and Italian bee, many others were induced to go into the business who became prominent writers for the bee-papers, or large honey-producers and queen-breeders and hive patentees, and still others are made worthy of record, and a sketch of their work would be interesting if time and space would permit.

The moveable-frame hive caused much rivalry, and some jealousies, but the patentees, and those they spoke and wrote of each other in not very complimentary terms—in fact, in language hardly admissible in polite society; but there were still more rivalry and jealousy, and bickering, between the queen-breeders and sellers of Italian bees that had not the advantage of the Italian or who were too much or too little, or intolerant of the impost or the fraud. Various tests of purity were advocated that added still more confusion to the matter. One writer, greatly perplexed over the matter, said:

"One dealer in Italian bees says the workers are distinguished from the natives by a yellow band around the abdomen; another says, ..."
three yellow bands or rings: a third makes the markings of the queen a test of purity, a fourth the purity of a queen by her progeny; and a fifth makes the very amiable disposition of the worker, or the "impecableness of temper," a test of purity. A person entirely unacquainted with bees, and who might judge by the different opinions of these doctors, if he purchased a queen, purify guaranteed, would hardly know where to look for a reliable test.

As a matter of course, the writer became very much interested in these new bees. I had kept bees all my life, and I had known that honey is a product of both male and female bees in the hive I adopted it—in 1862 or 1863, I think—and I determined to have some of these new bees.

As I have stated in another article, I came to Pelee Island, Lake Erie, in 1866, and one of the first things I did was to purchase a few colonies of these bees. I got bought only one colony on the Island, and I bought that, and went to the main shore of Ontario and bought two more colonies. These I soon had transferred to Langstroth hives. I found that the Island abounded in good bee-pastures, especially the unbroken thistles, basilwood, and I am a great lover of honey as well as bees.

About this time a number of breeders of Italian queens had come to Kelley's Island, Ohio, because there were no black bees there, and it was beyond the flight of black bees from the main shore, consequently they could rear pure queens without the possibility of having them mated with black drones. Kelley's Island being only a short distance from Pelee Island, I crossed the international boundary line—I had a fine opportunity to see these bees, and was not long in taking advantage of it. I found a number of queen-breeders there—Aaron Benedict, W. A. Flanders—"Professor" Flanders with his Apianarian Institute and bee-club; Alexander B. Charles, one of the oldest settlers of Kelley's Island, and the first person to demonstrate the adaptability of the Island to grape-growing, was also engaged in rearing queens. I paid Mr. Carpenter Shaffer two dollars each for queens, and he gave them home all right and successfully introduced them to two of my colonies.

The humorous side of queen-rearing on Kelley's Island was given by the editor of the Ohio Farmer in his paper in 1867. After a visit to the Island, he tells what he saw there as follows:

W. A. FLANDERS—the Bee Man.—Prof. W. A. Flanders—you may have heard of him—has his Apianarian Institute on Kelley's Island, and of course we want to have bees and hornets, too. Mr. Flanders has three families dwelling in busy harmony under every green tree in the neighborhood. Talk of big prices for Merino rams! Flanders can get more money for an Italian queen-bee, with three rings around her tail, than any ram-peddler can get for the best Vermont Merino in his flock. Flanders showed us (in a vial of alcohol) one of these amiable little female sovereigns, which had lain fat and fume with another amiable little female sovereign, for which, he declared with a sigh—which came from as low down as the seat of his broad pantaloons—that he was worth in gold and silver. But then the truth can be settled by arithmetic. Here are 50 other amiable little sovereigns, bred from this insect in the vial, for each of which Flanders can take from 50 to 80 dollars, and there are 50 others—to the next—the value of the whole, worth more money than a short-horn bull. The idea would be ridiculous if it were not true. But Flanders has improved upon the original Dr. Jacob Townsend, and instead of being satisfied with the flagging full-blood Italian with three rings, has gone one better, and showed us a queen of his rearing with four rings around her body, all of the royal purple and gold.

(In continuation.)

In-breeding—If Practiced, It should be Sparingly and With Good Judgment.

BY FREDERICK E. B. SIMPSON.

It is to be regretted that those friends who have been foremost in agitating the subject of in-breeding, have not yet been able to get the matter before the public, and especially those who have the educational advantages which would be of direct benefit to the practical bee-keeper. In this connection Mr. A. C. Miller, in May I Gleanings, might well make his requirement known to the wise among them, and possibly add a college education as another requisite. There is no possible doubt about the great aid these requirements would prove to the queen-rearer; but is not it very exceptional when a bee-keeper possesses all these requirements, and not be a successful breeder? Why, for this reason, do we not favor the comparatively successful breeder to the exceptionally favored? is not the commercially successful breeder and queen-rearer practical rather than theoretical, commercial rather than scientific? And can not the best results follow by those who have the educational advantages which make it possible for them to be familiar with the general laws of biology, and therefore strong on these points? In cases be prevented from being broadly practical (on a large scale) by reason of occupation or circumstances—can not these students formulate plans based on scientific truth, which the practical man can use as a basis for systematic breeding? The same successful breeder, if he should like, can be made to realize the greatest success of queen-rearing and should be able to rear queens so skillfully that no large honey-producer could afford to do anything except receive from such bred stock. To the end that some of these men might be satisfied, I will contribute my site by saying some things about in-breeding; although be it understood from the start that I do not believe we will ever get any really conclusive knowledge on this subject except by actually breeding the bees; the more so from the fact that we have nothing in the nature of a domesticated animal which forms any real parallel to the bee.

Herbert Spencer says: "Remembering the fact that among the higher classes of organisms fertilization is always effected by a male from one species (or variety) mated with a female from another variety (or species) and the germ-cell of another, and joining with it the fact that among hermaphroditic organisms the germ-cells developed in any individual are usually not fertilized by sperm-cells developed in the same individual, the question of the reality that the essential thing in fertilization is the union of specially fitted portions of different organisms. If fertilization depended on the peculiar properties of sperm-cell and germ-cell, as such, then in the case of a several thousand organisms it might be the case whether the united sperm-cells and germ-cells were those of the same individual or those of different individuals. But the circumstance that there exist in such organisms elaborate modifications of differences of difference whether the union and derivative in the united reproductive centers is the desideratum."

Mr. Darwin says: "I will venture to add a few remarks on the general question of close interbreeding. Sexual reproduction is so essentially the same in plants and animals that I think we may fairly apply conclusions drawn from one kingdom to the other. From a long series of experiments on plants, given in my book, 'On the Effects of Crosses, the results, in a great many cases, seem clear that there is no mysterious evil in the mere fact of the nearest relations breeding together; but that the evil follows (independently of inherited disease or weakness) from the circumstances of the usually imperfect sexual constitution. However little we may be able to explain the cause, the facts detailed by me show that the male and female sexual elements must be differentiated to a certain degree in order to unite properly and the birth of vigorous progeny. The closest interbreeding does not seem to induce variability or a departure from the typical form of the race or family, but it causes loss of size, of constitutional vigor in resisting unfavorable influences, and often of fertility. On the other hand, a cross between plants of the same sub-order or family which has been grown during some generations under different conditions, increases to an extraordinary degree the size and vigor of the offspring."

Some kinds of plants bear self-fertilization much better than others, and we have a vast number of vagrant species and plants, and it is proved that these plants can do this that is a cross with fresh stock. So it appears to be with animals, for Shorthorn cattle—perhaps all cattle—can withstand close interbreeding with very little injury; but when they are bred from closely inbred stock with no any loss of their excellent qualities, it would be a most surprising fact if the offspring did not also profit in a very high degree in constitutional vigor.

Until we can get something solid proof that these arguments are applicable to the specific case of bee-breeding, it would seem unsafe for any queen-bee breeder to do any in-breeding with the intention of selling the resulting stock; but only as a matter of reserve, to go on and try it in experimental work through several generations of bees. Few queen-breeders will
consider that they can afford to do even this amount of experimenting in view of the fact that outcrossing has none of the objectional features in the public mind that in-breeding possesses.

One of the bottom facts of in-breeding is that Nature never intended it to be followed. It is more than likely that in-breeding as originally practiced by man, and in the majority of subsequent cases, has been largely due to the same cause— the absence of an unrelated individual at the time an unrelated one was convenient and, in a word, outcrossing was usually accomplished quicker by in-breeding than by outcrossing (where breeds are dependent upon one or a few characteristics, of which vigor, fertility and size are among the most important), which is a considerable incentive where it takes several years for an animal to become effective. But with these two propositions would seem entirely inapplicable; for we seem to be able to obtain an ample number of unrelated individuals of equal value with which to breed, and with which to improve, and still have the advantage which can be obtained in a short time renders the second reason of little or no force.

In the breeding of horse pedigrees, that a few words on these subjects may not be out of place here, although there being nearly as much pro and con, we can expect little new truth from these sources, and that the old Aryan is almost in parallel to beehive-breeding, whereas, in the other, the breed has not been established a sufficient time to secure any amount of uniformity.

The Jersey cow possesses a pleasing color and form with a decided exception of her degenerated horns which often require an expert to trim them to a regular shape—and at her best gives a very large quantity of very rich milk, of which a comparatively small amount is required. Good qualities have evidently been brought about at the expense of vigor, fertility and size, for which it seems evident that in-breeding is responsible.

But is the Jersey a fair comparison? Nature so situated her in the narrow confines of a small island where every chance of in-breeding cannot be avoided, and there arises the question of whether Nature endowed her with some inherent power by which the evil effects of in-breeding would be mitigated to a certain degree—sufficient with the aid of skill in the breeders to prevent the appearance of a breed which if left entirely to Nature would have long ago become extinct. For on an island of such fertility that animals are staked out instead of being turned loose for pasturing, it would naturally follow that the greatest personal care and attention would be bestowed on such animals so continuously handled.

Then, too, the pedigrees of renowned Jerseys abound in renowned ancestors to so great an extent that it is practically impossible to find a line of demarcation between what has been the result of in-breeding and that which is due to skillful selection independent of in-breeding. And if it had been possible to breed these animals with as much care as they are staked and inseminated, it is reasonable to suppose (see the quotation from Darwin) that equally good qualities would have been obtained, not only at no expense of these qualities, but even with an increase in vigor and size.

With regard to trotting-horses, the general proposition will be found to be true that where in-breeding exists in a good individual that is able quite uniformly to transmit his good qualities to his offspring, such in-breeding is merely an expedient and not an advantage, whereas the real cause of quality is skillful selection. Then, too, the sources of trotting families are comparatively few, which renders the incident of in-breeding more frequent, and the results of the breeders, if skillful and successful, is seldom close, and, therefore, has but little effect. When trotting-horses were a "fad" they were largely bred with no other quality than that of speed, so that, although speed was often obtained, where we failed to obtain it we had only a failure that did not possess enough other good qualities to make it valuable. But as soon as the "bottom dropped out," the lesson was learned, since which time our greatest aim has been to produce such an animal as will possess that balance of qualities which will make him the highest typical representative of his species. At any rate we quite uniformly get a high type of horse. If his speed and racing quality are sufficient, we have that. We have always been more interested in the horse of this grade where there may be sufficient quality for a first-class roadster, or an excellent carriage-horse; lacking this, the barborously inclined can cut off his tail, blindfold his fore-foot, and get an inferior type of Hackney. And, finally, if some physical injury should occur we will, often, still have a good individual to breed from.

From all the observations I have personally made when I have received first-class in-breeding, in trotting-horses, I am led to believe it is a total failure; except, perhaps, in exceptional cases where two individuals somewhat over-sized, with a tendency towards coarseness, possessing possessing offspring, only until such increased length is the direct result of increased use of the tongue, indicating greater activity and vigor. Doubtless the direct issue of the original [priced] queen possessed this increased size, but is there not...
Questions and Answers.

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please don't ask the Doctor to send answers by mail.—Editors.)

Catching a Swarm on the Wing.

Is there any way of catching a swarm of bees after they leave the tree they first settled on? If so, what is the quickest and best way? MINNESOTA.

Answer.—I suppose you mean is there any way to stop a swarm when it has started to leave. It isn't the easiest thing in the world, but it is always worth trying. Perhaps the best thing is to take a looking-glass, run ahead of them, and reflect the sun upon them. That has been reported successful in driving them back in a number of cases. Some, however, will tell you that a better plan is to have a spray pump and throw a good shower of water upon them.

A Small Queen-Thick Combs.

1. I divided a strong colony of Italians in fruit-bloom, as you suggested some time ago, and the queen-cells started were all small. I left the largest ones, and, when hatched, the queens were not much larger than worker-bees, and feather-colored. I killed one of the queens and put the nucleus back into the old hive, and left the queen in the other division. The queen is two weeks old, and has not commenced to lay yet. Would you advise me to remove her and give them a larger queen? The old colony swarmed two days after I put the nucleus back, and the queen-cells started are large; the queen looks sleek, and is large like her mother.

2. I have considerable trouble getting straight comb in most of the frames having brace and burr combs on them. I don't think the frames were spaced properly when first put in. Would you advise buying an extractor, uncapping the deep ones, spacing the frames over again, and feeding sugar early in the fall? Will it pay me to get an extractor? I am running for comb honey and have eight colonies.

NEW YORK.

Answer.—1. If a queen does not begin to lay till after she is two weeks old, she will generally turn out very poor, and you will risk very little to kill her.

2. It might pay you to get an extractor, but not for the sake of straightening out your combs. Neither do you need to take any such trouble. If the center of the comb is in the center of the frame, and some of the combs are too thick (which I understand is the case), all you need to do is to keep crowding the combs together a few times on different days. The bees will trim off the parts that touch, all but a few points of attachment which you can remove, and a few operations will make all right. But you will be likely to have some brace-combs in any case.

Finding the Queen, Etc.

I have a very strong colony in an 8-frame hive which I wish to divide and can not find the queen, having looked the frames all over five different times. They have about seven queen-cells, most of them being capped.

1. What is the best way to find the queen?

2. Will a colony swarm if it has laying-workers in the place of a queen?

3. Will the bees build more drone-comb in the spring than in the early fall?

4. Can I divide, and use queen-cells? ILLINOIS.

Answer.—1. Usually all that is necessary is to look somewhat carefully over the frames. Avoid the use of much smoke, for if you smoke the bees till you get them to run, you may find as well give up finding the queen till another time. If you do not find the queen after looking over the frames once or twice, better close the hive and leave them for half an hour or longer. For the queen is probably hidden in such a way that it is impossible for you

HOME APIARY OF GEO. B. WHITCOMB, OF LINN Co., OREG.—See page 150

long-tongued colony will not go to waste but will be used to advantage in the more rapid storing of more easily reached nectar, regardless of its source. And it is quite pertinent to the subject, that the colony which has given me the most nectar to date, this season, from fruit-bloom, contains by far the longest-tongued bees I have, many having a reach of 22-100. And this also is a point in favor of my idea that the best bee is the best regardless of locality. Bee-Keepers' Review. Fulton Co., N. Y.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest beekeeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at $1.00.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

The Premiums offered this week are well worth working for. Look at them.
Some Swarming Troubles.

Will a colony of bees swarm without a queen? I assisted my father in hiving two swarms of bees this spring. The first swarm was put in a new hive with foundation ready for work. They stayed three hours and then left the hive, and we hived them three times in the course of the day, and each time in a new hive. The third time they moved out as quickly as they would, all right. We looked them over and found them in the same condition, and before we could hive them again they all started for the timber.

The second swarm we hived twice, and the third time we put a comb of honey in the hive and shut the entrance. We put them down cellar over night. The next morning they were all dead but about a pint, and we could not find a queen among them. What do you think was the cause?

Laura.

Answer.—I knew one case in which a swarm issued when there was no queen in the hive. But I had removed the queen from the hive only a short time before, and I suppose the bees had not yet learned of her absence. So it is safe to say that a swarm will not issue from a hive without they have, or suppose they have, a queen present. But even should a swarm issue in such very exceptional case without a queen, they will not go off without a queen, but will return to their hive or to some other hive in the apiary. It is not always easy to find a queen in a swarm, and if I like, I am inclined to think that there is a queen present.

The probable trouble was that the weather was very hot and you did not shade and ventilate the hive. Putting that swarm in the cellar was not a bad stroke, but you probably shut them in too tight that they smothered. After putting them in the dark cellar you should have given them a very large entrance, raising the hive well. A frame of brood is better than a frame of honey to give to a swarm.

The Afterthought.

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. Hasty, Sta. B Rural, Toledo, O.

FINGER-ITCH FOR RECONSTRUCTING.

What shall be done to me for my everlasting meddlesomeness? Can't see a good thing without finger-itch to see if I can make it better by reconstituting it. Now there's the striking verse on here which W. S. Hutchinson quotes to open his excellent paper on page 327. I want it to run:

"For the want of a nail the shoe was lost;"
"For the want of a horse the rider was lost;"

And a friend his slave friend did bewail
When his noblest steed had got a hoof nail.

And, if that rider had been De Wett
A nation lost in the end we'll get.

STING-POISON IN HONEY.

And so (according to page 344) in each 62 pounds of honey the bees put an ounce of sting-poison. The German writer didn't think of the thing in that shape, or the enormity of the pilfering, until after his book was published. He could find no way of stopping it, and said it was much more reasonable and just such a thing as might happen, though he didn't want it very much, and if it did happen he didn't want it. But even on that we must remember that breathing the volatile part has a very bad effect on some persons.

DEEP-TUBED AILSELE AND WHITE CLOVER.

E. R. Root contributes a good point in a red-hot controversy when he says he has seen both ailsle and white clover too deep-tubed for average bees to fully reach bottom. Page 345.

PARTHENOGENESIS.

It was more than a hundred years after Columbus sailed before we gave wide and vitally important a truth as the circulation of the blood was discovered! It's amazing. And one of the constitutions of the atmosphere remained undiscovered until the American Bee Journal had become an old paper. Why should man, a reasoning creature, be so great in fantasies?
The Home Circle.

Conducted by Prof. A. J. Cook, Claremont, Calif.

ORDER.

I doubt if "Order is heaven’s first law;" but I have no doubt that it is so well up to the front that whoever first asserted it got nearer the truth than most of us do. A more homely instance may be cited to understand it to be preached for general practice. Certainly not "t’ween cen.," Interesting to see they could not be jarred lower by any kind of bunting. Cousins to my bees, I reckon—and swarms have been unusually high-minded the present season. Page 364.

Moving Wide-open Hives with Bees.

Glad to see A. D. D. Wood advocate liberty for bees while being hauled from place to place. I have seen a little of this. Possibly it may not be practical for a big two-horse wagon; but for one or two colonies to be taken in a buggy I am quite sure it is much the better to let them have their door wide open. Smoke them just enough before starting, and keep the smoker ready for action on the road. Page 303.

Shooting Shot into Swarms.

Shooting charges of fine shot through a high-minded class‘ ter till the queen is killed and the cluster broken up—well, it is somewhat ingenious, and I do not understand it to be preached for general practice. Certainly not "t’ween cen.," Interesting to see they could not be jarred lower by any kind of bunting. Cousins to my bees, I reckon—and swarms have been unusually high-minded the present season. Page 364.

Mind, we can not afford to neglect it. The very success of our best ones has given us may turn, very likely will, on just this point.

It is often said that the competition in life is constantly becoming more and more severe. That likely is true. But it is even more true that the competition is very slight among the best. The men who really desire to be the best, their best, in all their work. And never neglect to teach them that if order is not success's first law, it is a very close second.

A very able and successful college president once said to me: "I can go into my library in the dark and take down any book I may wish to use." I always wondered if he could. Yet I knew him well, and if he really did not wholly correctly, the assertion marked a characteristic which did much to lift him to the high position which he so successfully maintained for many years.

Pets.

In our busy lives, I wonder if we are as careful as we should be to see to it that our homes are cheered and enlivened by numerous pets. We have two little kittens now in our home. They are so full of their antics that they have won all our hearts. We all are so thoroughly interested in them that they receive very careful consideration. Nothing in the home is too good for "Kitty Clide" or "Kitty Carson." I often wonder as I see people harass to their faithful horses and cattle, what their bringing up was. Did they have pets when little? and were they led to care for them? Do the kittens get affection? I don't know how any one can tell. I see the watch is of much account as a watch-dog. I am as sure that mousing is not the kitten's best use. Then let dog or cat, horse, cow or bird, have its best use in awakening and developing the sym pathetic, in quickening the affections and calling out that love and thoughtful care that is the best establishment in any life. Is it Eliza Cook that says in speaking of our pets of the home?

"And if to us one precious thing
Not their own—be—given,
Kindness to them will be a wing
To bear it up to heaven."

I have a feeling that my horse and cow are happier and feel safer when I am around than when they are away from me, that I am a better man for caring for them. Even the ants have pets in their homes, and they are the wisest among insects. May we not say truly that the wisest people will have numerous pets for their children?

Kind Words in the Home.

I know of one of the most spiritually minded Christian ministers that I have ever known, who believes that if we brought up our children as we should, they would need no change of heart. They would be right-minded and true to the sweetest and purest in life from childhood up. I wonder if harsh, unkind words are ever In place in the home. The parents who have influenced me most sweetly and truly never came at me with harsh look or bitter speech. I have taught school ever since I was fifteen years of age. I never yet used a whip. I have sometimes lashed with my tongue. I have had those thundered if such scouring was not what that child needed. I have a sort of theory that if we have love enough for our dear ones, we may push the harsh word and fault-finding out of the house, to the betterment of all left within. But we must be sweet ourselves always if we would win by this better way.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.
To Our Shippers.

About May 1st last, we removed our business from the buildings 120-122 W. Broadway to larger and more commodious quarters at Nos. 265-267 Greenwich St., and 82, 84, 86 Murray St., and we duly sent to our friends in the trade a notice of our removal. Shortly after we vacated the premises (120-122 W. Broadway,) one Joseph M. McCaul, rented a portion of our old quarters, and hung out a sign, "Hildreth, McCaul Co., Jos. M. McCaul, Prop.," with other large signs to the effect that his business is "headquarters for honey, beeswax, maple sugar and maple syrup."

The mercantile agencies report that Jos. M. McCaul is the sole proprietor of the new business, and that he claims to have paid to one Henry P. Hildreth (who has no connection with our business,) a consideration for the use of his name.

We will not comment upon the act of leasing our old quarters and exposing thereon the sign, "Hildreth, McCaul Co.," further than to state that we have instructed our attorneys to apply for an injunction restraining the said McCaul from using the name of "Hildreth" in connection with his business in any manner whatsoever.

We value highly the good name and business we have established by many years of satisfactory dealing with our friends in the trade, and we therefore send this notice so that you may not possibly confound us in any manner with the so-called "Hildreth, McCaul Co."

Our firm name remains as heretofore, and all our business is carried on at our new quarters—

Nos. 265-267 Greenwich Street,
and Nos. 82, 84, 86 Murray St., New York, N.Y.

Respectfully yours,

HILDBRETH & SEGELKEN.
DO YOU WANT A HIGH GRADE OF ITALIAN Bees and QueenS?

2-frame Nucleus with Undeisted Queen, $2.00, purchaser paying express charges.

Naperville, Ill., May 24, 1913.

Dear Sir:—Bee-keeping is a good business. Transferred them to have and gave them honey. Have reinforced them with hatching brood. Are working like a colt. Have right color, and are satisfactory. D. B. GIVLER.

American Bee Journal
July 18, 1905
Winds Cut Honey Crop Short.

Our crop is about 20 or 25 pounds to the colony of extracted honey. Hot, dry winds dried up the basswood and clovers on short notice this year.

Grant Co., Wis., July 6.

A Downpour of Sweets.

Williamson County, in which we did not drown the elephant last spring, is now receiving a large crop of sweets, and believe that the flow now on is the heaviest since 1897 or 1898. We have every prospect that it will continue as Fred. Bee-keepers are snatching a regular "bizz-smile."

O. P. Hyde & Son.

Long-Tongued Queens and Red Clover.

Considerable has been said, row and cow, about long-tongued queens. Why not get some red clover seed from breeden? A man who was born there told me that the bees work on red clover there all the time.

Beehives are pretty well now. There is lots of white clover, and it is full of nectar.

Greene Co., Iowa, June 25.

Outlook Discouraging.

The outlook for a honey crop in this locality is very discouraging. It has been so dry already and the flowers of it are so late that there are scarcely any flowers in bloom, although the bees are bringing in some honey from the clover.

A good many colonies started to death last winter. The spring was cool and wet until such a time that there were some surplus being stored along the creek bottoms, but it was all gone by the uplands.

R. C. Suppe.

Losses Heavy—Large Yields Per Colony.

Our losses were heavy last winter. On account of the mild weather bees flew most of the time, and they became aggressive during the spring fighting. I lost 25 out of 150 colonies in this way, sold 23, and 2 were queenless. In the only case where I kept bees that were queenless I built up as much as to store any surplus.

All colonies that were strong early in the season have done remarkably well, considering the fact that basswood did not yield on account of winds and dry weather; white clover secreted well during the early part of June, but is now yielding very little, if any. Ours have not been as good as our previous year, as we are getting any honey, and it is not yielding as profusely as last season.

All colonies in field of extracted honey from one colony up to July 1, is 400 pounds; another has finished 251 pound-sections.

We are expecting a fall flow, as the extremely hot weather has prevented the growth of the full nectar-secreting plants.

J. L. Gandy.

Richardson Co., Nebr., July 1.

The Bee-Keeper’s Guide;
Or, Manual of the Apiary,

BY PROFESSIONAL A. J. COOK.

480 Pages—1st Edition—1899 Thous.

$1.25 postpaid.

A description of the book here is quite unnecessary; it is simply the most complete scientific and practical bee-book published to date. Fully illustrated, and all written in the most fascinating style. The author is also well-known to the whole bee-world to require easy introduction. No beekeeper is fully equipped, or his library complete, without THE BEE-KEEPERS’ GUIDE.

This 16th and latest edition of Prof. Cook’s magnificent book of 6x9, 416 pages, with and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting NEW SUBSCRIBERS for the American Bee Journal.

Given for TWO NEW Subscribers.

The following offer is made to PRESENT SUBSCRIBERS only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year.

Send us TWO NEW SUBSCRIBERS to the Bee Journal [with $2.00, and we will mail you a copy of Prof. Cook’s Bee Book. Give the subscriber a premium. Prof. Cook’s book alone sent for $1.50, or we club with the Bee Journal for a year—both for only $7.50. But surely anybody can get only TWO NEW SUBSCRIBERS for a year, and thus get the book as a premium. Let everybody try it. Will YOU have one?

Foundation Sagging in Brood-Frames

C. Davenport describes in Gleanings in Bee-Culture his plan to prevent this, which does not require wire frames.

This sagging or stretching of the foundation, as those who have had trouble in this respect know, is next to the top-bar, a strip two-thirds inch wide over which the foundation has been fastened in a frame, and while it still remains in position on the board, the pollen of the eggs is being worked down to the foundation, two or three inches above the top-bar; then a small stream of wax is forced out. As the point is lowered to the top-bar, this adheres to the foundation; and if the operation is repeated at intervals the whole length of the top-bar, it will prevent the foundation sagging when the bees first get on it; and by the time they do, these strips of wax off the foundation are usually drawn out enough to hold it from sagging.

Hive-Covers and Bottom-Boards.

W. W. Somerford says in Gleanings in Bee-Culture that he prefers the plain reversible board cover for the climate of Cuba. Because it is cheaper, and because they warp with less force, he uses boards 1/4-inch thick in preference to thicker.

His bottom-boards are somewhat novel. After struggling with difficulties connected with ordinary bottom-boards, he says:

I scratched my head, got on my wheel, and started off with a Spanish-talking American bee-keeper to a new brood of foundation. We soon found the jolly owner, and told him just what we wanted—smooth and straight flat-pressed brick, 16 inches wide by 21 inches long, and 1/4 inch thick, and said he had just the "American machine" to make them with, and made them. And, Gentlemen, I can tell you now, as I place them on nice, flat ridges of earth, it is with a feeling that I shall be grown old and grey before the nectar of the honey bee shall show decay. The man who made them said they would last forever. Just think of a nice bottom-board that will lay forever and costing only 10 cents! If you have no tile factory to apply to, concrete or cement will make them—cheaper than the clothed in summer, and warmer than the warmest in winter.

Some Things About Queen-Rearing.

The following conversation, taken from the Australasian Bee-Culture, will interest beginers:

Fred—"I say, Will, you have introduced 24 queen-cells today—will they be laying in 10 days? I think you said a queen-cellar took 21 days to lay in 10 days."

Will—"Yes, Fred; I suppose I did say so, but those were not queen-cells I distributed, but queen-cells, and most of them will not emerge until to-night, so I will count full 10 days from that."

I believe I will expect to find them laying on the eleventh day, and will look them after that time.

"Will you not look at the nuclei before then?"

"Of course, I will make sure the cell has not been destroyed. I will look into the cell queens in about two days, and if I find them I will not disturb them before the eleventh day."

"Have you any object in not looking through them now?"

"Yes, I have, as if it were not for the frequent loss of queen-cells I would prefer not to touch the hives until the queen was due to lay. My rule is, don’t disturb my bees having a virgin queen—first, it is an unnecessary loss of time, and, secondly, the young queen often gets excited on the opening of

Red Clover Queens

LONG-TONGUED BEES ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with $2; or, one Tested Queen free as a premium for sending us FOUR new subscribers with $4.00).

We have arranged with one of the oldest and best queen-breeders (having many year’s experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder will use is direct from Italy, having imported his own bees. Our worker-bees are large, somewhat red. They stored red clover honey last season.

All queens guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, $1.00 each; Tested, $2.00 each. Send all orders to

Bee-Books

BEE-BOOKS

SOLD POSTED BY George W. York & Co., Chicago.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been thoroughly re-written and illustrated with new treats of everything relating to bees and bee-keeping, and is brought up to date. Contains about this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 529 pages, bound in cloth and illustrated. Price, $1.25.

Beek-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College. A clear and practical work, and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 496 pages, bound in cloth and illustrated. Price, $1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. DoLittle.—A method by which the very best queens are reared in strict accord with Nature's way. Bound in cloth and illustrated. Price, $1.25.

A BC of Bee-Culture, by A. L. Root.—A cyclopedia of 400 pages, describing everything pertaining to the care of the hive, and all about Comb 209 engravings. It was written especially for beginners. Bound in cloth. Price, $1.20.

Advanced Bee-Culture, Its Methods and Management, by A. L. Root.—A new and in many ways a better bee book than the author's work this is a practical and entertaining writer. You should have this bee book. Bound in paper, and illustrated. Price, 50 cents.

Rational Bee-keeping, by Dr. John Dzierzon.—This is a practical bee book for the latest German bee book on culture. It has 350 pages, bound in paper covers, $1.00.

Bien-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Bound in cloth. Price, 50 cents.

Bienenzucht und Honiggewinnung, nach der neuesten methode German (by J. P. Eigger).—This book gives a practical and scientific method of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject, 50 pages, board cover. Price, 50 cents.

Beek-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the subject of bee-keeping. It is the best manual of management in order to secure the most profit. Price, 75 cents.

Beek-Keeping for Profit, by Dr. G. L. Tinken—Revised and enlarged. It details the author's "new system" of "cheapest yield of honey and comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apian Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 20 colonies, $1.00; for 100 colonies, $1.25.

Dr. Howard's Book on Fouled Brood.—Gives the McEvey Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Fouled Brood Treatment, by Prof. F. R. Chevalier—In Case and Prevention. Price, 10 cts.

Cepos and Captivating, by Dr. Sawyer, Fanny Field, and other well known authors. All about pleasing bees, fascinating bees, and how to make the most money in bee keeping. Price, 25 cents.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Entertainment and information in diseases and their cure. 64 pages, 20 cents.

1901—Beek-Keepers' Supplies!—We can supply you with The A. L. Root Co's goods at wholesale or retail at their prices. We can save you freight, and ship promptly. Market price paid for beewax. Send for our full catalog.

Please mention Bee Journal when writing.

HONEY AND BEESWAX

MARKET QUOTATIONS

CHICAGO, July 5.—The new honey is arriving, and some nice lots of white clover comb have sold at $1.00 per pound. We have been supplied which is very light at this season the reported price for the June comb has been firming up to accommodate so that $1.50 would be acceptable if ordered; amber grades are nominal at $1.25. White extracted, half yellow, $1.75; amber, $2.00, dark, $2.35. The price of pure yellow, $3.00.

R. A. BURNETT & CO.

CINCINNATI, May 17.—No demand for comb honey, also stock of it well exhausted. Extracted very salty, sold down to $1 1/2 per pound, lower prices from 9/4 to 1 cent per pound.

C. H. W. WEHR

BOSTON, June 29.—There is practically no comb honey in our market, and owing to warm weather very little call for it. We are expecting some new candy horne next month. Market for extracted dull, at 65c to 67c.

BLAKE, SCOTT & LEB

OMAHA, May 1.—Comb honey, extra white, 25-cents cases, per lb., $1.25; new No. 1 amber, per lb., $3.00.

PHYRE BROS.

NEW YORK, July 6.—Our market is practically bare of comb honey, and demand good for white comb. Fancy stock sells readily at $1.50. White at from $1.25c; amber at 10c. Extracted, half yellow, $1.75; amber $2.00; dark $2.35. Good crop of Clover honey in this vicinity from what bees there are. The price of pure yellow comb has been raised by fout brood exterminators. H. R. WRIGHT.

BEE-BOOKS

REVISED BY DADANT—1900 EDITION

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large bee-keepers and bee-keepers of the district, to whom it is known to all the readers of the American Bee Journal—Chas, Dadant & Son. Each subject is clearly and thoroughly explained by the following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for $1.25, or club it with the American Bee Journal half year—one both for $1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with $3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

Italian Queens, warranted
Tested, $1.00: Untested, 75 cents, by return mail.
RIVER FOREST APIARIES,
Oak Park P.O., River Forest, Cook Co., Ill.

Please mention Bee Journal when writing.

SWEET CLOVER
And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

| Seed Type        | Price  
|------------------|--------
| Sweet Clover     | $1.00  |
| Anthriscus       | $1.25  |
| Alfalfa          | $1.25  |
| Japanese Buckwheat | $1.50 |
| Japanese Clover  | $2.00  |
| Japanese Clover  | $2.50  |

Prices subject to market changes.

Please mention Bee Journal when writing.

Red Clover Queens

We have been telling you through our advertisements of the superior stock of queens we are furnishing this year, and we have abundant testimony from others corroborating our opinion. Look at the following which is only one of the numerous endorsements received.

July 5, 1901.

The bees are working as I never saw them work before, and already there is over 100 pounds of honey in the hive, and all from clover. I am led to believe that long tongues and good working qualities go together.

Yours very truly,

Orel L. Hershiser,
Supt., N. Y. State Apiary Exhibit, Agricultural Building, Pan-American Exposition, Buffalo, N. Y.

This refers to a colony of bees on the Pan-American grounds with one of our Tested Red Clover Queens reared last season.

Our Prices are as follows:

- Gleanings in Bee-Culture one year and one Untested Red Clover Queen, $2.00.
- Gleanings in Bee-Culture one year with Tested Red Clover Queen, $4.00.
- Gleanings in Bee-Culture one year with Select Tested Red Clover Queen, $6.00.

If you want something good you can not do better than to order one of these queens. All orders are filled promptly. No extra postage on these offers to foreign countries.

THE A. I. ROOT CO., Medina, Ohio.

GEORGE W. YORK & CO., 144 & 146 Erie Street, CHICAGO, ILL.

ITARISE

To say to the readers of the BEE JOURNAL that the DOOLITTLE... has concluded to sell QUEENS in their season during 1901, at the following prices:

| Queen Type        | Price  
|------------------|--------
| Untested Queen   | $1.00  |
| Tested Queen     | $2.25  |
| Select Tested    | $3.00  |

Extra selected breeding, the very best...

Circular free, giving particulars regarding each class of Queens, conditions, etc. Address,
G. M. DOOLITTLE,
11A 24th
Brodino, Onondaga Co., N. Y.

Please mention Bee Journal when writing.
**Weekly Budget.**

Mr. F. B. Simpson, whose article on inbreeding appeared in last week's number of this journal, desires to make the following correction: I wish here to correct the error I made in my article in last week's issue. On page 422 I wrote, "My idea that the best bee is the best regardless of locality," I had in mind all the honey produced in the 4th paragraph in the 3d column on page 431, but failed to put them on paper, as they should have been if again mentioned, for I am a long way from believing the way the last sentence was printed.  

F. B. SIMPSON.

Editor E. R. Root passed through Chicago on his homeward journey Monday evening, July 15, stopping in the city only between trains. He had traveled about 6,000 miles, making some 15 stops, and was feeling well, having gained several pounds in aroricarpus. The Texas "bee-keepers' paradise," mentioned by him in a recent editorial item in his paper, is already greatly overstocked with bees and bee-keepers, so no one need get ready to move there right away. In Colorado and Utah, however, there are numerous locations that are excellent for bee-keeping.

**Langstroth on... The Honey-Bee**

Revised by Dadan—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 300 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the Ameri-
Editorial.

One of a Thousand.—Are you one of a thousand members that the National Bee-Keepers' Association ought to have before the convention to be held in Buffalo, in September? Last week we reported the names of four persons who had sent us their membership dues. This week we record the following:

New names will have to be sent in more rapidly than during the past two weeks if we are going to secure the necessary 200 among the readers of the American Bee Journal. That was what we thought could easily be done. And it can be—if only 200 among all the thousands who are not yet members of the Association would simply send in the one dollar each.

Of course, it is not necessary to send your dollars to us—send them direct to General Manager Eugene Secor. Forest City, Iowa, if you prefer. But we can publish the names of only those who send to us. We will then forward the money to Mr. Secor.

Now, can't we have a long list of new names next week?

Grading Honey.—Mr. D. W. Working has an article on this very important subject in this number of the American Bee Journal. Every bee-keeper ought to read it, and then heed it. We have handled enough honey to know that most bee-keepers know very little about the grading business. Of course, each knows that no other bee-keeper ever produced as fine honey in every way as his! And no one grades as honestly as does he! It is always the “other fellow” who puts the finest and whitest sections of honey in the front row, next to the glass, and then fills in back of them with “any old thing.”

One needs only to see the pronounced lots of honey that are received by a honey-dealer, to be convinced that on the subject of grading there is much to be learned by most bee-keepers. And uniformity of grading—well, you might almost as well talk of controlling breeding so that all colts or colts will be of the same size and color!

But it will pay to continue to call attention to this subject that really does mean so much to honey-producers.

Read Mr. Working's article, and then see if you can't hereafter do better work along the line of grading honey.

Bees Superseding Queens.—G. M. Doolittle says in the American Bee-keeper that fully three-fourths of his queens superseded by the bees are so superseded during the first 24 hours immediately following the linden flow. So any queen that he wishes to replace at that time is disposed of, and a ripe cell given a day later, unless a cell-protector is used, in which case the cell is given at the time of removing the queen. A plan not generally known he further gives:

Another plan which I have often used since my apiary became very much improved beyond what it formerly was, is to rear a lot of cells from my best queen at the time given above, and 24 to 48 hours before they are booked to mature, give one to each colony having a queen more than one year old, using a cell-protector for each one, and placing this protected cell in one of the sections on the hive, or anywhere I best can where the bees can cluster about it, without hunting out the old queen at all; when, if the bees have any notion to supersede their queen, they will accept of this young one and destroy the old queen. If they destroy the young queen I allow the old one to remain, thinking that the bees know what is right, and in 19 cases out of 20 where the bees decide on keeping the old queen, I find she proves passable well after the honey-flow of the next year is over. This is something which does not cost much labor, and which I practice often to my satisfaction.

In Breeding is generally supposed to be a thing that should in all cases be avoided, and bringing evil and only evil in its train. Those who are well-informed tell us that some of the best results in breeding have been obtained through the very closest breeding, and this has been emphasized so strongly that some might be led to think that no care whatever is needed to avoid in-breeding. A very white color in the honey is supposed by some to be the result of this, and the other side lies the teaching: In-breeding must never be allowed. On the other side lies the teaching: Pains must be taken to practice in-breeding if the best results are to be obtained. The truth in such cases is generally to be found in middle ground. In this case the middle ground would be very welcome to the lazy breeder, who would interpret it as being: take no pains to avoid in-breeding, and take no pains to practice it, but let nature take its own course. In this case certainly the middle ground so interpreted is not a safe ground.

We are told that in-breeding is not a bad thing at all. Perhaps, how can in-breeding be a bad thing when such grand results have been obtained through its practice? But were the results obtained because of in-breeding or is that just the fault? Darwin says there is no mysterious evil in the mere fact of the nearest relatives breeding together, but the evil follows from the circumstances of near relatives generally possessing a closely similar constitution, and that however the fact be explained it seems a fact that for the most vigorous progeny there must be a certain differentiation between sire and dam. That sounds like saying there is no evil in in-breeding per se, but it comes perilously near if it attendant circumstances are so commonly such that evil results. It would be unwise to dogmatize with none too much knowledge on the subject, but there may be no harm in asking a few questions:

Did those breeders who obtained such good results from in-breeding breed from near relatives because they were near relatives, or because they possessed, in common, qualities desired to be perpetuated? Would a father ever have been bred to a daughter as sire and dam if another than the father could have been obtained possessing the same qualities as the father without at the same time being nearly related to the daughter? Is it not the safe thing for those who do not take great and special care, that they shall take all the pains possible to avoid in-breeding? Is it not well that more should be known about the laws of breeding, so that a goodly number of the craft could be engaged in an intelligent attempt to improve our bees?

The Saw Palmetto is an important honey-plant. That same remark about white clover would perhaps elicit a smile of pity, for every one is supposed to know white clover honey, yet saw palmetto is to the Floridian bee-keeper, the editor of the American Bee-keeper says, that the Northern producer of honey. "Hundreds of thousands of acres of Florida sand are covered with a scrub growth of it, while in moist and richer localities it grows in impenetrable jungles, and is one of the most beautiful of our sub-tropical palms," so says Mr. Hill.

In the same journal, W. S. Hart says it is a tree whose trunk may lie under the surface of the ground or upon it, or it may rise 10 or 12 feet high in the air. It is one of the cheapest and best sources of tannic acid for tanning leather. The pinnate leaf is used to make paper, especially of finest quality, and capable of holding oil and other liquids. It also makes a very clean and springy filling for mattresses. The bloom is composed of small, cream-colored flowers on racemes from one to three feet long, and the honey is of a fine light-amber color, heavy in weight, and of good flavor. Another grade of honey is obtained by the bees from the juice which flows down through the skin of the berries, which are from the size of an olive to twice that, and seem to be a wholesome food for hogs, cattle, bears, and people.

Grading Honey—Its Importance, Rules, Etc.

BY D. W. WORKING.

Secretary of the Colorado State Bee-Keepers' Association.

The bee-keeper is a partner in a co-operative business; he furnishes the hive and its accessories and markets the produce with which he works. But he does more. Between the work of preparing the hive for the bees, and marketing the product of their labor, the bee-master has other work to do. He is more than a partner in a co-operative establishment; he is his manager and joint worker, and on the wisdom and skill with which he works and manages depend in a large measure the success of the business venture.

The bee produces the honey. But will it make straight comb, even, white, and well-capped, if hive and sections are not properly prepared for its use, and if they are not properly cared for during that use? And if all the preliminary work is well done, will the product be ready for an easy and even sale, and at a decent price? The fruit-grower picks his berries and his apples when they are in the best condition for the trade; he sorts them carefully and puts them up in attractive packages in order to command the best prices the market of the end. Sell in raising experience in handling, wisdom and foresight in catering to a varying demand—these are the secret of his success.

The bee-keeper must do more than to induce his bees to put their products into clean sections; he must keep the sections clean and unbroken; he must meet the demands of the trade. To do this he must take the honey from the hive at the right time, must make each section as clean and inviting as possible, and then assemble the sections properly into attractive packages. People like what is good, and like it better if it looks good. What is clean suits them better if it looks clean. A stain on the outside of a section does not make the honey less sweet or less wholesome, but makes it less attractive to the buyer. The stain, therefore, must be removed before the section is offered for sale.

Uniformity counts; therefore the bee-keeper must make his packages uniform—in size, in shape, in color, in arrangement. A few leaking sections are too many; a single badly graded case may spoil the sale of a ton of honey. So the individual must be careful in grading, in handling, in packing, and in selling his products. But this is nothing compared to meeting the demands of the trade. Sell in raising experience in handling, wisdom and foresight in catering to a varying demand—these are the secret of his success.

The rules and recommendations of the Colorado State Bee-Keepers' Association are as follows:

COMB-HONEY RULES.

No. 1—Sections to be well filled and capped, honey white or slightly amber, comb white and not projecting beyond the wood, wood to be well cleaned; cases of separated honey to average 21 pounds net per case of 24 sections, with a minimum weight of not less than 20 pounds for any single case; cases of half-separated honey to average not less than 213 pounds net per case of 24 sections, with a minimum weight of 393 pounds for any single case; cases of unseparated honey to average not less than 223 pounds net per case of 24 sections, with a minimum weight of 213 pounds for any single case.

No. 2—Includes all amber honey of a pronounced tinge, and all white and amber honey not included in No. 1; to be fairly well sealed, uncovered cells not to exceed fifty in any section exclusive of the outside row, wood to be well cleaned; cases of separated honey to average not less than 15 pounds net per case of 24 sections.

EXTRACTED-HONEY RULES.

Extracted honey shall be classified as white and amber, shall weigh 12 pounds per gallon, shall be perfectly free from particles of wax, and shall always be marketed in new cans. All rendered honey, whether obtained by solar heat or otherwise, shall be classified as "strained" honey and not as "extracted."

RECOMMENDATIONS.

It is recommended to sell all pure honey around home as much as possible, to grade only in daylight, near a window; to use the standard 14x13/16 inch section and the 24-pound double-tier shipping-case, in order to have uniformity in loading cars; to stamp all cases of No. 1 honey with the owner's name above the handholes; to mark all cases of No. 2 honey with two dashes in the handholes at each end of the case, and with no other marks whatsoever; to use no second-hand cases for No. 1 and No. 2 honey; to pack all sections with paper below and above, and in double-tier cases to put a sheet of paper between the tiers; to store comb honey in a warm, dry place, protected from flies and dust; and to handle carefully, well protected from dust and rain.

Do Bees Spread Pear-Blight?—The California Bee and Fruit Case.

BY E. R. ROOT.

TROUBLE has been brewing for some months between the fruit-men on one side and the bee-men on the other at Hanford, in the San Joaquin Valley, Calif. On the part of the first-named, the contention was that the bees, the property of the other parties, were the principal means of spreading the pear-blight, which had been working such awful havoc among the pear orchards in the vicinity mentioned. The bee-men, on the other hand, took the ground that their stock were not carrying the pear-blight; and, even assuming that they might do so, averred that other insects, and birds, as well as the wind, might and could do all the mischief laid to the door of the bee and that, therefore, the removal of the insects under the direct control of man would not afford the relief sought. The contention waxed warm. Each side called special meetings to discuss the matter. Bitter words as well as threats were used. Some of the more rabid of the fruit-men proposed...
to use poison to exterminate the bees in case they were not speedily removed by their owners. This only tended to aggravate matters. The bee-men retorted that, if any one were foolish enough to resort to such a procedure, not only killing the bees but endangering the lives of human beings.all they would in sight them on the way, half way; that they had, as backing, the National Bee-Keepers’ Association, which had hundreds of dollars to its credit, had fought many cases in court, and had always been successful. Furthermore, it was believed already on the question of poisoning bees, and that the fruit-men “could drive ahead” if they wished to. The latter maintained that they “had looked up the law.” and that they knew what they were about.

It appears that those who indulged the most freely in this war of words were not those who had the largest interests at stake, either in the bees or in the pears; that the large pear-growers as well as the largest bee-keepers were men who indulged in no threats, but who believed that a compromise might be effected between neighbors who were men of fairness as well as men who are willing to listen to reason, and so the sequel proved.

The president of the National Bee-Keepers’ Association was asked by resident members to make a visit to the scene of the impending trouble; investigate, and take such action as might, after a conference, seem most advisable. Accordingly, on the 18th of June, that officer appeared at Hanford, Calif., being received, as it were, into that “nest of hornets” by the redoubtable John H. Martin (Rambler), and J. C. McCubbin, who came with him officially and unofficially to see that no harm was done him; but, be it said, they deemed it advisable to go home that same day, although they did participate in one or two little “skirmishes” on the street. Unfortunately the Rambler had not along his invincible umbrella and stovepipe hat; for with such offensive and defensive weapons he would surely have come off victorious. As it was, it was a “draw” and he departed with John C. under his arm.

It appears that the local members of the Association had made a great handle of the coming of the president of the National; of the strength of our organization, how it had never lost a case in court, and that it had secured valuable decisions from the high courts. But as he did not come at the time expected, and days went by, and still he did not come, the fruit-men began to think that this talk was all “bluff;” and when he did appear, there seemed to be a feeling on their part that he had come, not to bring peace, but war, and that an organization that would send a “walking delegate” clear from Ohio surely meant business. Moreover, it had received both sides, a truce and a compromise began to be talked of. On our side was a special committee appointed by the Central California Bee-Keepers’ Association, at its last meeting, to meet the representative of the National Bee-Keepers’ Association; and on the other was N. W. Motheral, Horticultural Commissioner, of Hanford, Calif., who seemed to represent the fruit-men, but who some jokingly said was the mother of the whole trouble.

When both sides got together it was suggested by one of the fruit-men that, as a compromise, the bees be moved from the vicinity of the pear-trees during the time they were in bloom. This, after they were out of bloom, and when the alfalfa began to yield nectar, they be returned to the heavy or main crop. This, it was thought, would give them, in the meanwhile, a chance for investigation, and if, after investigation, it was shown that the claims of the fruit-men were well-grounded, afford in the meantime the necessary relief. This was finally agreed to, although it would entail a big expense on the bee-men.

It may be wondered why the latter were willing to listen to a compromise at all. In the first place, as they believed, the facts were in their favor. In the second place, the fruit-men had the testimony of Prof. M. B. Waite, Assistant Chief of the Division of Vegetable Physiology and Pathology at Washington, D. C. This official takes the position that bees do carry the spores of pear-blight from flower to flower while the trees are in bloom. In this opinion he appears to be supported by Prof. N. E. Pierce, Pathologist of the Pacific Coast Laboratory, Santa Ana, Cal.

The following letter, directed to N. W. Motheral, Commissioner of Horticulture at Hanford, Calif., from Prof. Pierce, explains the position of the scientists, in a nutshell:

Mr. N. W. Motheral, Horticultural Commissioner, Hanford, Calif.—

Dear Sir,—In fulfilment of your former letter, and in reply to your request, I herewith give the main facts upon which are based the claim that bees take an active part in spreading the disease of trees variously known as pear-blight, twig-blight, fire-blight, and barn-blight, which has killed or has threatened to kill the pear-trees in the locality mentioned.

1. Pear-blight is a bacterial disease which affects pear, apple, crab-apple, quince, and related trees. It is induced through the action of a specific micro-organism belonging to the bacteria, and known as Bacillus amylovorus (Barrell), de Toni.

These facts have been demonstrated by many scientific workers by careful inoculation, and by the recovery of pure cultures of the bacillus. The cause of the disease has therefore been well known for many years.

2. The identity of the blight of pear-trees in the Clow and Taylor orchards near Hanford (these particular orchards are cited only for the sake of accuracy, as there are many others affected) with true eastern pear-blight has been established, for Bacillus amylovorus was isolated in pure culture by the plate process from blighted branches from Mr. Clow’s trees, and a young and thriving pear-tree was inoculated, and died to within a few inches of the ground, with the true pear-blight. A control tree treated the same way as the inoculated tree, except that the bacillus was not introduced, remained perfectly healthy.

3. Mr. M. B. Waite, Assistant Chief of this Division of the Department, has kindly supplied the following additional facts bearing on this matter:

4. The occurrence of the blight on the blossoms in great quantities, and the great rapidity with which the disease spreads from flower to flower, indicates a normal and very effective method of distribution.

5. The germ were found growing freely in the nectar of the blossoms.

6. Bees have been repeatedly visiting the infected flowers, and some were caught taking infected nectar, and, by means of plate cultures, the pear-blight germs were isolated from their mouth parts.

7. By covering parts of the trees with sacks of various kinds of material, and then artificially infesting certain flowers on the tree, the blight was observed to spread very freely over the uninfected and uncoyored blossoms, but was entirely absent in the blossoms covered by mosquito-netting.

8. Pear-blight germs, germinated on the flowers, and lived up, and flourished for only a brief period on exposure to the weather conditions out of doors, hence they can not live in dust; and be blown around to any great extent by the wind.

9. Pear-blight virus, particularly which occurs on blossoms, is a very sticky substance, and is readily carried by insects, birds, or other animals, but can not be blown from flower to flower.

This brief presentation will, I believe, furnish your board with the main facts needed to show the connection existing between the visits of bees to pear-flowers and the spread of pear-blight.

April 23, 1901.  

Pathologist in Charge.

Prof. Pierce happened to be in the city at the time, and in an interview which we had with him he gave utterance to substantially the statements as are given above. If anything, his verbal statement is even stronger. So far as I could judge, he seemed to be a competent scientist, and a fair-minded gentleman; but, unconsciously, he is prejudiced, I think, in favor of the pear-men, with whom he has come much in contact of late.
I asked him if it were not true that wild bees, insects and birds, over which man has no control, could do all the mis-
chief ascribed to the bees. He admitted that this was poss-
ible, but not probable. Did he not think that bees were
valuable as fertilizers of the blossoms, especially of those
of the Bartlett pear? He thought they were. Well, did not
this furnish a reason to breed, year after year, more than
counterbalance the alleged mischief done by them? The
occasional year when pear-blight was so prevalent? He
could not say, although he was of the opinion that, by a
certain alternation of varieties, the services of the bee
might be dispensed with entirely; but of this he was not
sure.

From Prof. Waite's statements it would appear (to
express it in common parlance) that the bees have been
carefully observed and the results of their work noted.
He admitted that this was possible, but not probable.

This is a nice question, as a lawyer would say, and we
need to go at it carefully and candidly to get at the truth,
cut where it may.

There is some evidence that goes to show that Prof.
Waite is mistaken. For instance, there are young pear-
trees, acres and acres of them, that have never been in
bloom; and yet these young trees are blighted to death.
How? How is the reason did the bees carry blight to
these trees when it is apparent that they never went near
them? And then there are little shoots that have pushed up
from the ground since the big trees were in flower, and
yet these shoots are blighted like the rest. Assuming, for
argument's sake, that bees may carry the blight on old
trees, we must admit that there is some agency, possibly
the wind, Prof. Waite to the contrary, that carries the
destructive microbe to the young shoots and the young
trees. That is one of the things that are not explained.

Again, I believe we have the right to insist, for the
present, until we have more corroborative evidence, that
wild bees, other insects, and birds, over which man has no
control, may be able to spread the blight just as much as
the bees under the control of man. For example, this illus-
tration was used: If a barrel full of water has two plugs
in it near the bottom, the larger plug, represented by the
tame bees, and the other plug (the small one) by insects,
birds, and wild bees, will not the small plug exhaust the
barrel just as surely as it did in the case of the bees. If
this large plug only once out of every ten removal of the bees
to be allowed would not bring the relief expected, by a
long way.

In conclusion, let me say that I visited the worst-
affected large pear-orchards in the vicinity of Hanford,
California. The trees were blooming, the flowers were
fair, intelligent men. While they thought the bees were to blame, they also thought the pear-men had some responsibility in the
matter.

I visited one orchard of 120 acres, and every tree was
badly blighted, and no mistake; but in this orchard we
found the badly-blighted little shoots I have referred to.—
Gleanings in Bee-Culture

California for Bees—Motherwort, Etc.

BY PROF. A. J. COOK.

PROF. C. P. GILLETTE, of Colorado, desires me to give
the comparative merits of the different parts of California
for bees. The last list of the St. Louis entomological meeting
I came here there have been but 3 excellent seasons, while
two of the seasons were complete failures. It is possible
that at some time in the future we may be prepared to water
large areas in winter, when there is too much water and
when water can be had cheaply, and so remove this un-
certainty. In such case Southern California would lead the
world.

Central California—the great San Joaquin Valley—is
becoming very noted as a locality for bees. The extensive
fields of alfalfa in Fresno, Tulare and Kings Counties, make the honey crop almost certain; and the quality of the alfalfa honey best.

In Northern California there are always abundant
rains, and in some sections, as along the Sacramento river,
there are extensive areas of alfalfa. If the North had as
fine honey-plants and in as rich profusion as the South,
then Northern California would be at the head for honey-
production.

Prof. Gillette asks especially about Sonoma County. If
one is sure of honey-plants he may have no fear. It would
be better if possible, to locate close by a large acreage of
alfalfa, as then failure would be almost sure of elimination.
There must be generous watering in winter to insure nectar-
secretion. The owners of alfalfa will look to the water-
ing; and so the honey crop will be assured.

MOTHERWORT AS A HONEY-PLANT.

Mr. Arthur A. Houser, of McDonough Co., Ill., sends a
good sample of this plant, of which he writes:

I send you a flower which grows abundantly here. I haven't
been able to find a botanist that can give me its name. I please name it through the American Bee Journal? The bees are on it from early morning till late at night. I feel sure it must be a very
rich honey-plant. Do you not think I would better encourage its
growth here, as it flourishes well with half a chance?

This is one of the best mints of the East. It is the
common motherwort—Leonurus cardiaca. It is illustrated in my
"Bee-keeper's Guide," page 357, where I fully explain its use as a honey-plant. It is one of the best honey-plants, and so
has excellent relatives in the horse-mint and white and
ball sages. It belongs to the family Labiatae, so named from the
two-lipped or bi-labiata form of the flowers. Such irregular flowers have developed, as we are assured, that
they can be identified. The flowers are square, and
other families with irregular flowers are familiar in the
Scrophulariaceae and the Leguminosae. In the first is the
excellent honey-plant—figwort—and in the latter all the
clovers. The irregular flowers of the first develop so
as it reaches in to get the nectar, is sure to become dusted with
the pollen, which, as the bees flies away, will be borne to the
stigma of the next flower visited. The very fact of
irregular flowers tells that we have honey-plants.

CORRECT USE OF NAMES.

I trust if we can be too careful in using names cor-
rectly. I have the impression that to use a name tend to be
to get untruth, and, conversely, to use words precisely
works to make one more truthful. This, and to be
more correct in our language, is surely enough to influence us all.
Languages I would say—butterflies are all
the common faults of expression. I say faults, though the
dictionaries may permit some of them. Our dictionary
makers are conservative, and follow rather than lead in
nice distinctions. The best way to gain the latest and best
language is to work the words of specialists. They must be accurate
and precise.

The entomologist would never call a larva a worm. In-
sects are a branch separate from worms, and are very
different in every way. A worm—an angle-worm is an insect—
is always the same in form and appearance. Thus a worm
just hatched from the egg is like the mature worm,
except it is small. Worms have no feet, nor any specialized
organs for breathing. We may rightly say angle-worm,
sea-worm, tape-worm, round-worm, etc.

The larvae of insects are different. They are very un-
like their matured selves—usually have feet—have respira-
tory organs. If these are to develop into butterflies or
moths, we call them caterpillars. The caterpillars can always have from
10 to 10, legs, usually the latter number. If they are to de-
velop into two-winged flies, like house-flies, we call them
maggots. These are footless. If they are to become bee-
tles, we call them grubs, which usually have 6 legs, though
some, like the grubs of weevils, are also apodous or
footless. Another mistake is to call insects bugs. Only
one order of insects are bugs. We may say chinch-bug cor-
corately to call insects bugs. We may say chinch bug
as to call a rat a hippopotamus. Let us do all we can to
secure more accuracy in the use of such names.

Los Angeles Co., Calif.

Queenie Jeanette is the title of a pretty song in sheet
music size, written by J. C. Wallenmeyer, a musical bee-
keeper. The regular price is 40 cents, but to close out the
copies we have left, we will mail them at 20 cents each, as
long as they last. Better order at once, if you want a copy
of this song.
No. 9.—Practical Lessons for Beginners in Bee-Culture.

BY J. D. GERHING.

I BELIEVE it is safe to assert, Mr. Bond, that in all the
intelligent universe, so far as our knowledge extends,
there is not a creature so low in the scale of intelligence
that it does not in some degree appreciate human kindness,
gentle sympathy—all expressed in the word love. Of
course, it is easy to deny this statement; but it is by no
means easy to prove it false, in theory and manifestation.
Only a moment’s reflection brings before your mind the
fact that when I bid you to do your duty, to look after
your horse, your dog, or even one of your hogs, love—
as far as an animal is capable of manifesting that quality
of intelligence.

But I came to the conclusion a few years ago that we
have no safe guide by which to draw the line of limitation,
in the scale of intelligence downward, beyond which we
find no evidence to support my statement, when I read in a
journal of science of a man in England who had trained
quite a number of fleas—to such an extent that he could
hitch them to a cart purposely made for them, and to draw
it, as horses do a wagon. And several other things he had
taught those little creatures to do—all by the constant
and persistent exercise of tact, patience and kindness toward
them.

“I don’t pretend to know how a flea can appreciate human
kindness—I am only speaking of the fact as reported. I am convinced, however, mainly by personal observation,
that among our bees there is a kind of conscience, a
mysterious way they can and do appreciate kind treatment.
In the same way I have also learned that they have a keen
appreciation or comprehension, of the other kind of treat-
ment they are subjected to, as well as I do how promptly and
effectively they resent it.

“Looking at the matter, therefore, from the point of
view here indicated, Mr. Bond, it is surely not a waste of
time on my part to make the explanation of this principle
a feature of our lessons.

“Several times, on various occasions, visiting friends
have asked me, when they saw me at work among my bees,
how I could do it all without getting stung to death. My
answer nearly always is, Because my bees know me. They
seem to know my touch. Possibly they also know my
voice. Certainly they know me by their keen sense of
smell.

“Mark that last statement well, Mr. Bond,” I continued,
looking sharply into his eyes through the meshes of
his bee-veil as I spoke. “It is of greater importance than
you may think; not because it is a controverted propo-
sition among the most intelligent of bee-keepers, but
because as a test of your attention between you and me, it
implies that I mean it, that I believe it because I have been
convinced of its correctness by evidence that satisfied my
reasoning.

“‘Yes, Mr. Bond,’ I continued, impressively, ‘it is one of
the articles of my bee-keeper’s creed, that, Bees have a
keen sense of smell, and I’m ashamed of it—neither am
I fanatical enough to be ready to fight for it. And—let me
tell you this in strict confidence, Mr. Bond—whenever I
hear of an intelligent, well-educated man who, as a pro-
fessional bee-keeper, denies, point-blank and on foot, that
article of my creed, I intuitively suspect him of all, or at
least some, of such unprofessional habits as the smoking
and churning of tobacco, drinking of whiskey, and eating of
garlic and limburger cheese.

“I know very well that it sounds like a silly paradox to
make a statement of that sort,” I hastily commented, when
I saw through his veil a plainly outlined expression of
insolence. “Surely, since most of these fellows are jovial for
the cause, the thought naturally suggests itself that the best
trained and most loving bees in the world would be sure
to ‘go for’ such a man, hot-end foremost, if he ventured
with his bee-veil on to the honey-flow. The proposition
naturally assumes a paradoxical look of that sort. But the
paradox is at once seen to be a delusion, in a practical
way, when I explain that it is because of that fact of the
bees, ‘that you may be sure, Mr. Bond, that a bee’s sense
of guilt of offending their olfactory nerves persists in deny-
ing that the sense of smell is an inherent part of bee-
nature. They do go for him.”

“I fear I have wasted time in an effort to make you see
the point of my argument, which I can so plainly see and
feel. But, nevertheless, I trust that my effort to handle a
delicate subject through the texture of the proverbial ‘kid
gloves’ is not wholly lost.”

The conciliatory sentiment was offered because I knew
that my friend and pupil was guilty of the tobacco habit:
though not of the other two.

Beg your pardon for this digression, Mr. Bond, and
for keeping you waiting for the main article, which is
headed: ‘How to Get Rid of Little Bee-Smell.’

If you’ll now examine the smoker to see that it is in working
order, we will finish taking off that super. Of course,
you remember my caution not to lift before you are sure
you have a secure hold at both ends, and to be careful not
to drop any bees while you are doing it.

Following my directions, Mr. Bond lifted one end of the
super high enough above the frames so that he could
blow a little smoke underneath it among the bees, to pre-
vent them from making a demonstration when the super
was lifted clean off the hive. As he did, I said:

“This as a precaution,” I explained. “It is better to
do that, though it’s a little more trouble because you must
handle the smoker and one end of the super at the same
instant. If you lift the super suddenly, the bees
underneath are startled, not knowing what is going to hap-
pen, and, as a rule, they make a rush. The result is that
often, before you can properly take care of the heavy
super—supposing it to be full of honey—you get bees
to the thousand and all across the floor and into your
stocking. You want to take your stand to do the work you came there to
do. To say the least, it may cause some unnecessary
annoyance to have it that way. But there are times and circumstances
when—what is the word?—there is something to
which annoyance may be the result. As, for instance: the entire
colony may become alarmed and assume a belligerent atti-
itude, especially when you are handling old bees, and at a
time when there is a light honey-flow. Or, the color
enters the hive you are working at may be aroused by
the alarm-signal given by the flying bees. In that case
they will first mingle with those in the air to investigate
the cause of the commotion; but, almost invariably in
such an instance, these neighbor-meddlers will next pro-
cede to investigate the open hive, with the result, well-
known to all practical bee-keepers, that you have a case of
robbing on your hands when you were least expecting it.

I am telling you all this at this time, Mr. Bond, in
order that you may be prepared to make a safe emergency
whenever in the future you have a job like this to do. An
ounce of prevention is worth a pound of cure,” applies
here, Mr. Bond, in the sense that a little precaution, with
a little smoke judiciously applied, will often prevent—well,
it’s hard telling what not. Every experienced bee-keeper
will endorse that, I think.

“Now for the drones,” I said, after Mr. Bond had
deposited the super, without crushing bees or getting stings
on his fingers, and had made himself as safe as possible.

“Please take this prying instrument”—handing him
my old chisel—“and show me how nicely, carefully and
gently you can loosen the ends of those brood-frames with
it without alarming the bees. They are all glass, more or
less securely, hence you must avoid sudden snaps and
jerks.”

Mr. Bond took the chisel and bravely began the job.
He was getting along very well until he reached the last
frame. The bees had done a little more work on that, seem-
ingly, than elsewhere, and as a consequence my friend had a
little more trouble with it, and was obliged to use a little
more force to loosen it. Quite suddenly—as such mishaps,
especially in the case of the bees, happen so often and so
unexpectedly—his shell slipped and down went the frame with a
bang. Before I had time to use the smoker, or he to realize what had
happened, about a score of bees made a dive at his naked
hands. Fortunately, I had held back the smoke to keep his hands
perfectly still for a moment and not to jerk them back; for if
he did that they were sure to sting. This he now remembered and put
into practice, with the result that, though most of the
attacks were bee-keeper’s wounds, by the mere nuisance of
stinging, none of them made earnest of it.

“Good! good!” I shouted approvingly. “Now you are
initiated, Mr. Bond. That kind of experience is to the
baptism of fire. His first lesson at any rate, and his first
is to an army recruit. I think you can stand fire now, Mr.
Bond, when you and any man’s bees get into a fracas.

“Go ahead now and lift those frames out for inspection.
You can do it as well as I can. Begin with the one
you have just loosened and hand it to me; I want to see
whether there is any drone-brood on it or not.”

To be continued.
Biographical.

Mr. Robert Wilkin.

We present on the first page this week the latest picture of one of the leading pioneer bee-keepers of California—R. Wilkin. His son-in-law, Mr. J. F. McIntyre, has kindly sent us the following biographical sketch:

Robert Wilkin was born near Londonderry, Guernsey Co., Ohio, July 4, 1829, and died at Newhall, Calif., May 30, 1891. He leaves two daughters, Mrs. J. F. McIntyre and Mrs. J. M. Owens, and 8 grandchildren.

He was educated at Westminster College, New Wilmington, Pa. Soon after leaving college he married Eliza Williamson, who had attended the college at the same time. He had one daughter, Harriet, by this marriage, his wife dying when the child was 9 months old. About 4 years later he married Isabella Gordon, by whom he had one daughter, Mary. His second wife died in 1888.

Mr. Wilkin made a specialty of the bee-business for nearly 40 years; he left a journal of the business from 1862 to 1901, in which I find many interesting items. His first investment in this line was to buy the patent-right to make and sell the Langstroth hive in several counties in Ohio. This venture was not a financial success. The next was to buy a lot of black bees, transfer and Italianize them, and commence the business of selling Italian queens, and colonies, at Cadiz, Ohio.

Among the first items that he paid L. L. Langstroth $25 for an imported Italian queen, and sold 20 colonies of Italian bees at $20 each. An item in November, 1871, says: "I have 300 nuclei, and have sold this year over 800 Italian queens at $5. 10 years ago I received this season 2,000 queens; 400 of these were sold at $250 per hundred, and the balance at $8 to $6 each; and bought of A. Grimm 72 colonies of pure Italian bees at $11 each."

This was too good to last; for on May 15, 1873, he writes: "Of the 3,135 hives of bees in the fall, only 61 are alive now."

"June 5, 1873, bought of Dr. J. J. Adair, 52 colonies of bees at $6 each." He continued to lose his bees in winter and buy more in the spring to carry on queen-rearing, until the spring of 1874, when he moved all of his bees and family to Oskaloosa, Iowa, to try producing basswood honey. After two seasons of failure and loss of bees here he moved all of the bees he had left—240 colonies—and his family, to San Buenaventura, Calif., arriving Nov. 6, 1875.

In 1874 he wrote a book of 96 pages, entitled "Hand-Book of Bee-Culture," price, 25 cents. But he gave away more than he sold, to save himself the trouble of answering so many questions while selling queens. The book is now out of print.

After coming to California he turned his attention entirely to the production of extracted honey. California honey had not made its reputation at this time, and it was hard to dispose of large crops, and on Nov. 1, 1878, he left his bees in charge of C. Gallup, while he went to England to sell his crop of 45,000 pounds of extracted honey. Subsequently he made trips to Boston and Texas to sell honey. His largest crop was 100,000 pounds from 1,000 colonies in 3 apiaries in 1882. He retained his interest and enthusiasm in bees to the time of his death, and was actively engaged in hiving swarms when he was taken with cholera morbus, and after 12 days’ sickness died on May 30, at the age of 71 years and 11 months.

Mr. Wilkin was president of the California State Bee-Keepers’ Association during the last two years. His hobby was co-operation. He was always willing to lend a helping hand in a good cause, and served his country during the Civil War in the 42d Ohio Volunteer Infantry.

F. M. McIntyre.

One by one the bee-keeping pioneers are passing away. Soon there will be none left to give personal reminiscences of the days of Langstroth, and Quinby, and Wagner.

California has perhaps led in the line of extensive apiaries. Mr. J. S. Harrison (still living, we believe) leading one at a time with his 6,000 colonies of bees—the largest bee-keeper in all the world. Next to him likely came Mr. Wilkin, at least in the size of his honey crops, as mentioned by Mr. McIntyre.

But what of the future of bee-keeping? Will there arise worthy successors of the noble ones who have lived, labored, and then passed on? Yes, we believe there will be. Already a new interest is being taken in bees and the production of honey in many localities. The bee-keepers of the present are taking advantage of the experiences of the past, and with the progress of the present will undoubtedly surpass even the wonderful results attained by those of the years gone by.

Our pursuit is an honorable one. Indeed, "Our toil doth sweeten others." And as the years come and go, "others" will include more and more of the sweet-loving public that now know not the taste of "nectar fit for the gods"—delicious honey.

Above all things let us strive to emulate the grand examples as shown by the lives of those who have been translated to that Heavenly sphere, such as Langstroth, Quinby, Cary, Wilkin, and many more that might be named did time and space permit.

The Afterthought.

The "Old Reliable" seen through New and Unreliable Glasses.

By E. E. Hasty, Sta. B Rural, Toledo, O.

LIVING ON HONEY ENTIRELY.

I wonder how nearly a man could come to living entirely on honey—a man not a laborer, but one whose work is mainly mental. In other words, I wonder how much of a lie that is on page 365 where it says Pythazoras lived only on honey. I have hung up in my den a funny picture entitled, "George Washington trying to sell a lie." May it not have been that this was the one he was trying to sell?

A QUEEN KIND OF ORNAMENT.

We've seen many sorts of things to ornament apiaries, but never strings of decapitated human heads before. Ask Mr. Huan. if his State has "done gone" and annexed itself to Borneo. Frontispiece No. 24.

COUNTING BEES BEFORE THEY'RE HATCHED.

My parents came to Ohio in 1843. Suppose I should reason on how many Hasty's of the stock there ought to be here, instead of saying how many there are. When a chap starts in to count a colony of bees by saying: "The queen has laid so many eggs per day," or "The bees are in their second fall," or "The bees not hatching," and then to hustle him toward the door—just a little, you know. Counting bees before they are hatched is not better mathematics than counting chickens before they are hatched, but decidedly the reverse. Amount of inside surface in the hive, and generation of bees to the square inch, will yield a better approximation than egg-counting can do. Yes, we'd like to know who's got the most numerous straight colony; and it's sadly awkward that weighing bees is so much trouble except at swarm-hive-time. Page 371.

A HOMELESS QUEEN.

I would say to Mr. Crafton, page 881, that it isn't very common for queens to be lighting down upon us at our work. As for one way it might have happened, per chance a colony had been superseding its queen, and as usual reared several of them. Two chanced to emerge about the same time. One was accepted; and then when the bees not wishing to wear a queen was driven out of the hive. Finding herself homeless she presumably the open hive you were at work at to see what it might offer in the way of a home.

BEES AND GROCERIES.

Dr. Mary McCoy writes up an exceptional location in an entertaining way on page 385. Abundant pasturage on two first-class honey-plants, and scarcely anything else. One could well afford to do some feeding in spring if tolerably sure of a midsummer and fall with fair honey-flow of white honey. It looks as if grocers as well as other men are reasoning creatures. Unusual quantities of bees shipped with the fruit, when a masked apiary close by comes to need shipping. In a small city, where the number of dealers having exposed

NATURE STUDY.

"Flower in the crenniled wall,
I pluck you out of the creamy
I hold you here in my hand,
Little flower; and if I could but understand
What you are, root and all, and all in all,
I would know what God and man is."

Those beautiful lines from the great author, Tennyson, are rich in suggestion, and show the heart of the great poet-laurate of England. It is beautiful for us all to know the flowers, to know the birds, to be intimate with butterfly, moth and beetle. These gems of God's handwork are intrinsically beautiful. To be on speaking terms with them, to look deeply into their beauty and mysteries, day by day, is to enrich and refine the life. Poring into their wondrous secrets is ever full of sweetest and best entertainment, is ever startling us with surprises, is ever bringing us to know more of God's wondrous ways.

And how we constantly learn to see more and more as we study these wonderful tri-colorings right from God's own hands. Did the great poet oversate the truth when he said that to know the flower thoroughly was to know God and man? I am sure, to know the flower and insect will bring us as near God as will anything we may study, and will make us more alive with the best peace-makers, or stir up in the country folk more and true than others, may it not be that the influence of plant and flower has worked to sweeten and ennoble life?

New York, through a beautifully wholesome work of Cornell University, is bringing nature study into all the country schools, and so into all the homes. God be praised for this splendid undertaking. We may well bring it into all our home circles. Can we not get all our Nature Study to follow New York's text? Writable example, and all have the leadlet, the lesson helps, and every bid to foster this glorious nature study? Let us all urge it upon our colleges and legislatures. A little seed here will bear if in the soil of one mind the first ones away and don't let them get begun. Tell them also that screening often is only needed for two or three days, until a mysterious change in weather conditions makes the flowers “give down”—after which the flowers have the preference.

QUEEN ACCEPTING THE COLONY.

I think Editor Pender is on the right track in juggling our minds concerning the fact that the queen must accept the colony as well as the colony accept the queen. Curiously hungry is the person (or the people) on her side, and the opposite of hunger a very necessary peace-maker on their side. Page 388.

PARTLY FILLED SECTIONS FOR HAI.

Let's sing some more about taking partly filled sections, bees and all, to start laggards at storing honey. No experience myself (so I can sing more freely). I have wondered just a little if the wise old chaps who recommend this have figured high enough that the good old fellows. You see, if we let a good hand spend half his days making a tramp work, and said tramp does $1 of a day's work, we have scored a loss of 25 percent. My practice is, and my advice is strongly in the same direction, to keep bees for comb honey that don't need any such fussing. Page 397.

HINTS ON SELLING EXTRACTED HONEY.

On page 388, G. H. Pond strikes the heart of an important mistake. The queen can be depracates too large sales at one time. A lot of old candied honey well punctured with dead flies and ants—well, if an adversary wanted to keep a honey-loving family from buying any honey 800 years he couldn't contrive any better way. "Got a great lot of it on hand and can't buy till we eat it up." And it looks so repulsive they never eat it up. His experience with grocers is also interesting. Told many of them just how to reloliquify—they said they would—no one ever did. "Spots that would be pretty much the same everywhere. If an old fellow is done and prevent them at all, the man who furnishes the honey must see to it that it is kept in liquid condition.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by addressing to us the addressers who actually do not send copies, so that they may be acquainted with the paper, and subscribe for it, thus putting themselves in the line of knowledge with the bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

The Premiums offered this week are well worth working for. Look at them.
To Our Shippers.

About May 1st last, we removed our business from the buildings 120-122 W. Broadway to larger and more commodious quarters at Nos. 265-267 Greenwich St., and 82, 84, 86 Murray St., and we duly sent to our friends in the trade a notice of our removal. Shortly after we vacated the premises (120-122 W. Broadway,) one Joseph M. McCaul, rented a portion of our old quarters, and hung out a sign, "Hildreth, McCaul Co., Jos. M. McCaul, Prop.," with other large signs to the effect that his business is "headquarters for honey, beeswax, maple sugar and maple syrup."

The mercantile agencies report that Jos. M. McCaul is the sole proprietor of the new business, and that he claims to have paid to one Henry P. Hildreth (who has no connection with our business,) a consideration for the use of his name.

We will not comment upon the act of leasing our old quarters and exposing thereon the sign, "Hildreth, McCaul Co.," further than to state that we have instructed our attorneys to apply for an injunction restraining the said McCaul from using the name of "Hildreth" in connection with his business in any manner whatsoever.

We value highly the good name and business we have established by many years of satisfactory dealing with our friends in the trade, and we therefore send this notice so that you may not possibly confound us in any manner with the so-called "Hildreth, McCaul Co."

Our firm name remains as heretofore, and all our business is carried on at our new quarters—

Nos. 265-267 Greenwich Street,
and Nos. 82, 84, 86 Murray St., New York, N.Y.

Respectfully yours,

Hildreth & Segelken.
Northern Italian Queens!

Reared from Imported Pollens.

Our stock is so carefully bred and selected, as to secure car-loadings of honey. Locality (free from soil and other diseases), and the climate and past annual results, are considered.

PRICES:
1 untested Queen, $1.00, & for $5.00; 1 tested Queen, $1.50, & for $7.50; best Imported Queens, $6.00; fair imported, $5.00.

Sweet Clover—White-Eyed Drones.

A few months ago I had the pleasure of visiting a bee-keeping friend, one of the veterans in our State, whose painstaking and noticeable bee-keeping might be thoroughly appreciated by all that pertains to the craft may well be an inspiration to those of more slipshod ways. He is modest and unassuming, and one can listen to him talk. He remarked that he had seen nothing from me in the bee-papers for a long time, and I had to own it and admit that the creatures keep me so busy that I have not much inclination to write. They are doing better this time of year than they have done in mountains and valleys. I am growing a little field of it, and also having a few bees in woods and gardens.

It blooms here early in June—just about a month ahead of the white variety, which I have already noticed. It promises to be a boon to my locality, coming as it does when ordinarily there is little for the bees to gather from. I have had to feed bees in May for the past two years, but this year I must either divide colonies or take care of swarms.

I had been thinking that my enthusiasm was waning somewhat under the pressure of crowding duties, but it all comes back to me when I get after a swarm.

It is not unusual to find one or more drones that seem to be normal, except that they have white eyes. I don’t remember noticing any of that kind in 1913, and don’t know what to think of them.

Mrs. A. L. Amos.

FRIEND YORK—I notice on page 441 that “Afterthought” thinks it important to comment on an item contained in a private letter to the Journal. I thought proper to publish it in May 36th issue. Now, there was no theory advanced respecting bee-keeping, nor anything else, but in the statement of what point he seeks to make I am too dull for comprehension to discover. If he intends to cast discredit on the statement of fact, he simply advertises himself as anything but a gentleman.

May it not be that the “winged” him—as specimens would say—as he may be a dealer in second-hand cans—old Standard Oil Co. cans—any old rust that he can palm off on the public, or perhaps space to fill, or anything with which to fill it, the idea may be kept applied to the column over which he presides, in numbers of instances which might be referred to.

For instance, take the item headed, “Mr. Doolittle and C. C. York.” This Bee Journal could be filled with arguments, facts and figures, to show the falsity, or fallacy, of the charge made. It must be a lie, if it be gathered from what he says. If foreigners come over here and invest their money, somebody ought to make a profit, and it is always the better for every one concerned in the business, from the highest to the lowest laborer, if they finally sell out and take their money back to a foreign land, some one has made enough to buy them out, and has the business, but we invest, in most of our cases, their money goes into large business enterprises, like railroads, or manufacturing industries; if their bonds are finally paid with the accrued interest, it only shows success of great enterprises.

No one need worry, nor have any sleepless nights over our bees, and we stand all such drafts upon our life-blood—the old ox in the pasture—doesn’t realize that it’s even to talk. But why bring the subject up?

Again, referring to the “daughter thrown in,” in the manner in which he does it. There are many wealthy Americans, as well as many who are not so wealthy, whose daughters, worthy of every mark of consideration and respect, and ourselves as parents—such as myself, and I presume "Afterthought" would claim for himself—to select a partner for life from among those they think proper, as many of them marry husbands of foreign birth.

But to return to the cans. Those cans were bought of George W. York & Co. How does it happen that, or what does he say, that, in order to take care of “many oxes” were paid for, or lost on them? Of what interest is it to him, or the public, whether much or little was lost on them, unless, as suggested, he may be in the second-hand business?

WM. M. WHITNEY.
Kankakee Co., Ill., July 15.

Good Season for Bees.

This has been a very good season here, and the bees are doing nicely.

J. W. R. SHERMAN.
Suffolk Co., N. Y., July 12.

Dry and Hot.

I have 43 colonies of bees, all in fine condition, and things are very dry and hot, the temperature being 104 degrees in the shade. Yet my bees are gathering some honey from sweet clover and almond.

J. D. HITT.
Jo Davies Co., Ill., July 16.

Selecting a Home Before Swarming.

Two years ago I had an empty hive under a shed not more than 10 feet from the working colonies. One day my wife said that I saw bees coming out of that hive, and wanted to know if I had put a swarm into it. I replied that I had not. That afternoon a swarm issued from one of the old colonies, and we put it into that hive. The next day a swarm came to us from the north, and settled on a small cherry-tree not more than 20 feet from where the empty hive had been. It looked very much as though that stray swarm had intended to take possession of that empty hive, but finding it gone they settled on the cherry-tree. I got out.

On June 15 these swarms went together, and in 17 days the brood-chamber was filled, and I took off 24 fine sections of clover honey.

YOUNG BEE-KEEPER.
Logan Co., Ill., July 8.

Heavy Losses—Ahead of Dr. Miller.

I find that some bee-keepers in this locality have had bad luck, having lost all they had. A great many colonies died in the fall, or over wintered, as they were, about here at that time. I saved 10 out of 22, and this is the first time I ever lost any in wintering.

One day my wife said to me that she saw them to this season. I have one colony that has not swarmed in five years, and they have only returned more than twice. They seem to be very weak now, and I think the queen must be worn out.

I have worked with bees off and on, ever since I was a boy. I am longing for a cold, and never have to wear glasses. I can take dog and gun and hunt from morning till midnight, and I have a fine coat, and my wife is 74, and quite strong. We have been married 56 years, and have had 15 children.

I keep bees because I like them. Sometimes they are somewhat ugly, but if 500 were to sting me it would not hurt.

HENRY WHITE.
Humboldt Co., Iowa, July 1.

The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but of cents; or we will send it with the Bee Journal for one year—for only $1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

GEORGE W. YORK & CO.,
144 & 146 Erie Street,
CHICAGO, ILL.
An Overgrown Putty-Knife.

This is a tool used with great satisfaction by E. S. Miller in the apiary. He tells of it in the Progressive Bee-keeper:

Made of about one-sixteenth inch steel, 2½" inches broad at the sharp end, tapering to about 1½" inches 6 inches in length, for where the handle commences. The handle is made of two half-round pieces of wood riveted on each side, the same in color as the tool. The tool is useful as a butcher-knives or table-knives. It is ground alike on both sides, so that it does not matter which side is up when it goes out of the case.

When I get this blade between two bodies, or a body and cover, and begin to pry, it has to come, no matter how much bees. The tool being large and strong (nearly a foot long) gives a great leverage, and so great effort is required in using it. I can take it slow and steady and bring two bodies apart without a snap. It will take the bare-comb from two top-bars at once. It has to clean bottom-boards, queen-excluders, and, in fact, almost anything where scraping is needed. I frequently use it to dig with when leveling up hives.

Improving Our Stock.

Here are some words well spoken by "The Worker," in the Australian Review:

We're forming rules for judging Italian bees, I would place the winners that way:

Honey-gathering, 80; prolifecity, 10; gentleness, 5; color, 5; total, 100.

It is much easier to breed for color than for honey-production, that it will be some time before all of the bee-keepers in our land get into line. Some will say, "Oh, the Italian bees are good enough as they are, so long as we keep them of the threedbanded strain." Others will say, "We want our bees to look beautiful; they will get the honey they are good for in the flowers." This is a mistake a great many make. I have had a lot of people say to me:

"What is the use of all your fussing and breeding this and that? If there is no honey in the flowers the bees can't get it, no matter where they are." I admit that, but when there is honey in the flowers the good strains will gather much more than the poor ones will. It is not so noticeable in a good season as a rather poor one. Before I commenced breeding for honey-gathering my colony would vary much in the quantity of honey stored. I remember one year one colony gave me over 100 pounds of honey, while others gave only 50 pounds, and the average of the yard was under 20 pounds per colony. How I wish I had that queen now.

By careful breeding I now have my bees as nearly alike as regards honey-gathering as one could desire. Last year there was scarcely a point of difference in the whole yard, and it was only a fair season for honey. Brethren, let us be ever on the watch for the bee-keepers who breed bees entirely for honey, and then breed from her, thus ever improving our stock.

Stimulative Feeding in Spring.

This has sometimes been spoken of as a two-edged sword, cutting both ways. Practised at a time when bees are tempted to fly out in bad weather only to be lost, it may tend to diminish rather than increase the number of bees in the hive. G. M. Dollite gives in the Progressive Bee-keeper another phase of the matter, as follows:

During all the past we have heard much of stimulative feeding, with no hints that such might be a failure at certain times, but from past experiences, I find there are times when feeding, or other stimulative

A Foster Styling Pen....

This pen consists of a hard rubber holder, tapering to a round point, and writes as smoothly as a lead pencil. The point and needle of the pen are made of platinum, alloyed with WENNY-JACKS, an entirely different metal of great durability which are not affected by the action of any kind of ink.

They hold sufficient ink to write 10,000 words, and do not leak or blot.

As they make a line of uniform width at all times they are unequalled for ruling purposes.

Pens are furnished in neat paper boxes. Each pen is accompanied with full directions, pen and cleaner.

**Best MANUFACTURING PEN ON THE MARKET.**

19,000 Postmasters use this kind of a pen. The Editor of the American Bee Journal uses the "Foster." You should have one also.

How to Get a "Foster" FREE.

Send two new subscribers to the American Bee Journal for one year, with $2.00; or send $1.00 for the pen and your own subscription to the American Bee Journal for one year; or, for $1.00 we will mail the pen and you.

Red Clover Queens

LONG-TONGUED BEES ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with $2; or, one TESTED Queen free as a premium for sending us FOUR new subscribers with $4.00).

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veiling or smoke. They stored red clover honey last season.

All queens guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, $1.00 each; Tested, $2.00 each. Send all orders to

GEORGE W. YORK & Co., 144 & 146 Erie St., CHICAGO, ILL.

Please mention the Bee Journal when writing Advertisers.

work, brings no adequate returns. The queen lays as if she is led into a field by the workers, and the workers will feed her only this stimulative food when there is some reason to expect fresh food to be available. And while feeding will bridge over three or four days of bad weather, or even a week, yet there are a time when they seem to be in hopeless and certain to be in a condition that they will make no further efforts at "expansion," till they see some sign that there is to be propitious weather in the future. And during such long-continued, cold, spell the queen is the press, and I have found that the colony which was fed every day had very little. If, any, more eggs or larvae in the hive, the end of two weeks than did those having a reasonable allowance of stores, which had not been feed at all. But when we have fairly comfortable weather, but a dearth of nectar from no flowers being in bloom, or those in bloom not yielding any nectar, then good results can be obtained in feeding, or other ways of stimulating.

Close Imitation of Natural Swarming.

This is given as follows by G. M. Doolittle, in Gleanings in Bee-Culture, in a conversation with a neighbor, the first question being asked by Mr. Doolittle:

"Have you any queen-cells on hand?"

"I suppose there are plenty in any of those hives which have swarmed during the last week."

"Can you tell why I asked about the queen-cells before we get through. Now, to the plan: Take a box holding from three to six hives, and place in each box a side board a few feet from the hive you wish to make the swarm from, raising the front edge on a little block, enough so the bees can run under. Now make up the hive you wish to make the swarm from, and find the queen, earring her on one of the combs, when all the frames are put back in the hive again, the bees will make a plenty of unsealed honey, upon some along the top-bars of the frames and close the hive. Now we will quite a minute at the entrance of the hive, and rap on the sides of it, as you would in driving bees, rapping at intervals, and leaving the entrance open so that the bees returning from the fields may enter the hive. In from five to eight minutes open the hive and take out the frames and shake the bees in front of the box, and thus continue till you get at least three-fourths of the bees in the box. When you come to the frame which has the queen on it, place her at the entrance of the box, and let her run in with the bees. When you get the desired amount of bees in the box, put the frames back in the hive and close it.

Why do you run the bees into such a box instead of into a hive all prepared for them?"

"If you will not be impatient I will tell you so you will see the reason. Now, we will suppose that you have three-fourths of the bees and the queen in your box. You are next to take the box of bees to the shade of some tree and lean the box against the tree in an inclined position, with the open side of the box outward, leaving it there three-quarters of an hour, at which time you will find them clustered in the upper part of the box as they would be on the limb of a tree, if they had swarmed. Then you take out the three-quarters of an hour, if you have more to make, keep on making from other hives in the same way. At the end of the time place the bees that are in the box, the same as you would hive any natural swarm. Put the hive on the ground until you want to move them and see that all of them go into the hive, and they will stay and work the same as a natural swarm would."

"Then this leaving them the three-quarters of an hour with the open side of the box out is to make them think they have left home, so they will mark their location as does a swarm?"

"Exactly."

"I see now why mine would not stay when I shook them into a hive. But what about what is left in the old hive?"

"The next day, after making such a swarm, give the old colony a queen-cell from one of.
the lives you say have much, giving cells from the colonies which have those the nearest ripe, and the work is done. If you have stopped to think as we went along you will see that you have been of ages in your 'made swarm,' just as there would be in a natural swarm, and that each bee has its sac full of honey the same as they do when they come out themselves, the drumming casting them to fill themselves full more completely than they do when swarming. By being left three-quarters of an hour to cluster in the box they mark their location anew, the same as a natural swarm, as you expressed a few moments ago.

"But is the old colony in as good condition as if it had swarmed naturally?"

"I think so, fully, and more so; for in natural swarming the first young are not brought out-apiary, this is entirely a false view. It treats of everything relating to bees and beekeeping. No aparian library can complete with this book, for it is a complete work. L. A. L. Langstroth—The Father of American Bee-Culture. It has 200 pages, bound in cloth, Price, $1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultur- al College. This book is instructive and helpful as a guide in beekeeping, but is interesting and thorough practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 400 pages, bound in cloth, and illustrated, Price, $1.00.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doellinger—A method by which the very young queens are cut out in perfect accord with Nature's way. Bound in cloth and illustrated. Price, $1.00.

Advanced Bee-Culture, Its Methods and Management, by A. L. Root. A work for the beekeeper who is interested in the science of beekeeping. The book has over 400 pages, and is one of the best bee books ever written. Price, $2.00.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown of Georgia. A practical and concise guide for the beginner in the management of honey bees. It contains over 200 pages, and is one of the best bee books ever written. Price, $2.00.

Bee Keeping for Profit, by Dr. G. L. Tinker. Revised and enlarged. It details the author's beekeeping system, and how to get the largest yields of comb or extracted honey. 250 pages, illustrated, Price, $2.50.

Apiary Register, by Thomas G. Newman. Describes the methods used by professional beekeepers in the best manner. It contains over 200 pages, and is one of the best bee books ever written. Price, $2.50.

Capping and Capping, by Dr. Sawyer, Fanny and Emma. All about capping and capping, and how to make the best honey in the world. Price, $2.00.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowl, by Fanny and Emma. "Tell Everything about Poultry Diseases and Their Care." Price, $2.00.

Red Clover Queens

We have been telling you through our advertisements of the superior stock of queens we are furnishing this year, and we have abundant testimony from others corroborating our opinion. Look at the following which is only one of the numerous endorsements received.

July 5, 1901.

The bees are working as I never saw them work before, and already there is over 100 pounds of honey in the hive, and all from clover. I am led to believe that long tongues and good working qualities go together.

Yours very truly,

OREL L. HERSHISEK, Sept. N. Y. State Apiarian, Agricultural Building, Pan-American Exposition, Buffalo, N. Y.

This refers to a colony of bees on the Pan-American grounds with one of our Tested Red Clover Queens reared last season.

Our Prices are as follows:

Gleamings in Bee-Culture one year and one Untested Red Clover Queen, $2.00.

Gleamings in Bee-Culture one year with Tested Red Clover Queen, $4.00.

Gleamings in Bee-Culture one year with Select Tested Red Clover Queen, $6.00.

If you want something good you cannot do better than to order one of these queens. All orders are filled promptly. No extra postage on these offers to foreign countries.

APIARY OF E. M. HAYES, SAUK CO., WIS. — (See next page.)
Weekly Budget.

The THOUSAND Members for the National Bee-Keepers' Association are coming.

Since our last report we have received the membership dues from following:

B. H. TRIPP, H. A. DOTT

REV. M. MARIN, of Henry Co., Ind., wrote us July 28, as follows:

"My bees have hived this summer. When I get time I will tell you more about it. In a month I will complete the 60th year of my ministry, and I can easily preach four or five times a week.

Mr. Mahin desires to be congratulated on his good health and ability to continue in his work. May richest blessings be his.

The OFFICIAL EMBLEM of the Pan-American Exhibition was designed by Raphael Beck, of Buffalo. It was accepted as the most artistic and suitable from several hundred designs submitted, and has the special merit of effectively symbolizing one of the chief purposes of the Exposition, which is to bring in closer social and trade relationship the Republics, States and Territories of North and South America. The emblem shows a fair maiden typifying the North, extending a kindly hand to clasp that of her brunette sister of the South, thus forming a bond of continental sisterhood, and establishing a unity of sentiment and interest among the countries of the Western Hemisphere.

Mr. E. M. HAYES, of Sank Co., Wis., began to keep bees ten years ago, with one colony in a dry-goods box, somewhat larger than the hive he is now using, and the bees wintered well in it without protection. He now uses the 15-frame Langstroth hive, principally, and has adopted the tiering-up plan.

While he does not consider his an ideal location for bee-keeping, he never gets less than 50 pounds of honey per colony, and he has secured as high as 100 pounds per colony, and some increase. He sometimes gets light honey from clover and bergamot; there is no asparagus in reach.

Mr. Hayes says that buckwheat is a much more valuable honey-plant than many give it credit for being. It comes late in the season, thus giving all colonies that were weak in the spring a chance to build up strong. While some think it is too little for manufactur-
Honey in Cans vs. Barrels.—Although we fear having our motive misjudged, we feel that we ought to say another word on this important subject. We certainly would refrain from referring to it now were it not for the fact that additional experience simply confirms us in the belief that extracted honey ought to be put into 60-pound tin cans rather than in wooden barrels.

We received two 400-pound barrels of very fine honey from Florida recently, and after we had almost positively declared that we would not purchase any more honey in barrels. One of the barrels leaked, as usual! Both absorbed a number of pounds of the honey, also.

True, a tin can will occasionally burst, and thus cause leaking. But when it does, you can't lose more than 40 pounds out of one 60-pound can. But a barrel—well, we have more than once seen over a half-barrel of honey lost through leaking, or from the head bursting out.

Yes, tin cans do cost more than barrels, but they are worth more, and for several reasons. The honey in them can be re-liquefied without digging it out and putting it into something else, as must be done with honey in a barrel. Honey in 60-pound cans is in better shape for the cash honey-dealer to handle. It is a quantity that many a family feels it can afford to buy at one time. Other excellent reasons might be given.

It may do to put dark or cheap honeys into barrels, but the fine white extracted honeys we think ought always to be put into 60-pound tin cans. We believe the day will soon be here when such honeys will be required in tin cans, and perhaps at a slight advance in price over that of the same grade in barrels.

Another Victory for the National.—The National Bee-Keepers' Association has won another notable victory in the courts. General Manager Secor sends us the following condensed account:

EDITOR AMERICAN BEE JOURNAL.

In December, 1900, the city of Rochester, N. Y., had under consideration the passage of an ordinance prohibiting the keeping of bees within the city limits. W. R. Taunton, a member of the National Association, living in the city, and whose business and liberties would be interfered with by such an ordinance, appealed to the general manager for advice and assistance. Such printed matter as it was thought would be of service to him was forwarded, and, with the assistance ofable legal counsel, Mr. Taunton succeeded in having the proposed ordinance withdrawn.

But in April, 1901, the matter was revived, and through the persistent efforts of one of the aldermen, and in spite of all objections and remonstrances, the ordinance passed.

Mr. Taunton was advised not to remove his bees, and assured that if he got into trouble the Association would defend him.

Mr. Marks—a director of the National Association—was requested to go to Rochester and make a complete investigation. He did so, and reported that in his opinion Mr. Taunton was handling his bees in a manner not to annoy neighbors, and thought the ordinance ought to be repealed.

In corresponding with our attorney, Mr. Buckler, the latter stated that the police judge, before whom the case was likely to come, was an able man, and thought the Association would better risk it there.

The case was tried upon a warrant of arrest for refusing to comply with the ordinance, and the Judge of the Police Court rendered his decision, setting aside the ordinance, and discharged the defendant.

The Judge gave his written opinion.

General Manager Secor, Head Bee-Keeper N.Y. & B. K. Association.

The above case was referred to editorially on page 323. Surely, another victory is won by the "Old Guard." But such victories can not be won without expense to the Association. And the only source of revenue is from membership dues. So each bee-keeper who cares for his own rights, or that the rights of others shall be protected, should be a member of the National Bee-Keepers' Association. You may not have to call on it to aid in defending you—and then you may. No bee-keeper can tell what he may be unjustly prosecuted or threatened. Better "get in the dry!" before it rains, and thus take no chances of being caught unprotected.

See the first column of the second page of every issue of the American Bee Journal for information concerning the Association.

Forcing Honey into the Super.—The Australian Bee-Bulletin says:

Putting frames with eggs and unsealed larvae at the outside of the cluster the bees don't want to store right in the middle of the brood-nest, so put all surplus in the super.

That will work all right some of the time, but when a heavy flow is on, bees will often allow solid combs of honey right in the middle of the brood-nest.

Bottling Honey.—J. R. Schmidt tells in gleanings in Bee-Culture about the practice of H. W. Weber, the successor of C. F. Muth, who succeeded in building up a good trade in granulated honey. Instead of following that up, Mr. Weber goes to the other extreme, and sends out honey that will not granulate. That he succeeds in doing so may be really seen from the fact that some honey put up and sealed last summer had been kept on ice since bottling, and after passing through the present winter, is just as clear as it was the day it was put up, and not a case of granulated honey had to be replaced this winter.

The secret lies in putting the honey in much the same way that fruits are put up—having everything hot at time of sealing. The apparatus used by Mr. Weber is good, but it is probable that apparatus for putting up on a smaller scale might cost very much less. There is for heating the honey a tank within a tank, with a three-inch space between the two for water. When the granules are all melted out of the honey, and when for five or ten minutes the honey has been kept at 180 degrees, it is drawn off into the bottles, the cork is hammered in with a nailot of solid rubber, and then dipped into a melted preparation of rosin and beeswax, making it perfectly air-tight. If honey thus put up will keep indefinitely without granulating, it will much simplify matters for those who now go about taking up from grocers' bottles of honey for re-liquefying.

An Artificial Swarm is thus directed to be made, in Bienewasser:

Take from the hive all the combs with adhering bees, except the comb on which the queen is found and a comb of honey. Fill up the hive with frames containing starters, and close the hive. The combs taken from the hive, with their adhering bees, are to be put in a new hive and placed on a new stand, having water furnished to them for four or five days. The field-bees will all join the old queen on the old stand, and the colony on the new stand will rear a new queen.

In this country it would be considered a gain to give the new colony a laying queen or a mature queen-cell.

Steam Wax-Presses vs. Hot Water.—Rambler lands steam wax-presses in Gleanings in Bee-Culture. They may be excelled by those in which the material while in press is all the time kept under hot water. These are in use in Germany, where steam presses have been in use a number of years, and it is said that those who have tried both, prefer the hot water.

A Cheap Bee-Stand certainly is the one recommended by Loyalstone in the Australian Bee-Keers' Review. He says "Nothing better, and cheaper, to my mind, than making mounds of earth, well buttered down, rising about four inches above the lowest level of the ground." In some localities—perhaps rather in some soils—this may work all right.

Moving Bees Into the Buckwheat Fields.

By F. Greiner.

Perhaps the reader may think that there isn't anything to be said on the subject of moving bees into new places, and this may be so, but I think there is a lot that may be said on what applies to moving out-apisaries in the spring also applies to moving into buckwheat sections. I admit, in a measure, this is true, but when we take into consideration that our bees toward August 1 are in altogether different conditions, and we may be asked by the reader to bring them out of place to offer some suggestions in regard to how we may manage this matter.

If there has been a honey-flow previous to buckwheat time, our hives will be found quite heavy, and the handling of these frames may be done in a leisurely manner, but when moving the bees into buckwheat fields, the frames should be removed and the combs may be taken out of the frames, nailing wire-screen over each. These ventilators answer a double purpose when fastened to the top of the hive. In the first place, they give plenty of air while moving; secondly, they allow the smoke to escape and give ventilation while driving the bees out of their old home into a new one, which is our first step in the preparation for moving our bees into the buckwheat sections, for we prefer to leave all these heavy brood-combs at home, and take only the naked bees. So, accordingly, we proceed.

The "driving" requires but little time, but some skill. The colony is raised up from its bottom-board and so placed as to give us easy access to the underside of the frames. Then with hive-combs, the section-case and the ventilating screen, all fastened together, are placed on top, and by the judicious use of smoke from the bottom, and pounding on the brood-chamber, the bees are forced up into the empty hive, etc., in a very few minutes. When this is accomplished we lift off the new hive with fixtures and bees, and place it upon the same bottom-board and stand the colony previously occupied. We put on the cover and let it remain thus until we are ready to move three or four days later. We wish to let the bees become acquainted with, and adjust themselves, to the new state of things before moving them, or else some might swarm out as soon as opened up in the new location. Occasion for swarming will swarm out the next day after "driving," and must be hived back with a queen secured by an entrance-guard.

The old hive full of brood and honey is placed right back of the hive containing the bees, for a little while, perhaps an hour, not more, or till we have evidence by the behavior of the bees of the forced swarm that their queen is with them. When we feel sure a queen is left in the old hive, we are obliged to make a search for her, and when found place her where she belongs.

The hives with their brood comb may now be placed around the new home, left at home, two or even three upon a single colony. Excluders are used to keep the queen from below to enter the brood-chambers above. We manage these sets of brood-combs for increase, as explained later.

The question might be asked, Why not furnish these forced swarms only with foundation starters? Indeed this might answer as well, or even better, as far as the securing of comb-honey is concerned. However, it is not safe to move newly-hived swarms long distances—the combs give the bees a chance to cling to during the journey; and then we wish some honey stored in these small brood-chambers for wintering. We are quite sure to accomplish this end by furnishing the combs instead of starters.

When selecting the colonies to be moved we pick out such as have old queens. We may have to double up in order to get them all collected, but when we get them we have old queens we avoid the possible sacrifice of young queens. When the season is getting near its end, this doubling-up may commence. It can better be done at this time after the heat when moving into new fields. Instead of this doubling-up we may reunite them with the parent colonies, providing we do not wait too long before we take them back to the home yard.

It has not been fully explained just what was done with the sets of hives that we left brood, except that they had been placed upon other colonies over queens excluding honey-boards. Our practice is to leave them alone for five or six days. Quite a good many young bees will have hatched out in apisaries, and are well sealed. We then take them off, bees and all, place each one on a bottom-board and move to a new location. If we have any queens on hand, we supply them with such; if not, we have taken the precaution 10 days, previously and started queen-cells from our breeding queens. These are then just ready, or ripe, and each new-formed colony receives one. In due time these will hatch, and the young queens will fill the hive with brood sufficiently to insure a good bee and add to the population. If these should not be as strong as desirable, then those colonies brought back from the buckwheat pasture may be united with them as mentioned. We kill the old queens, of course; thus we have economically removed all our colonies that were moved into the buckwheat.

I can recommend the above plan as one giving us better results in comb honey than any other, and an increase in bees, if we desire the increase. Ontario Co., N. Y.

Advertising High Values for Queen-Bees.

By Frederick F. Simpson.

Having been much interested in the recent discussions regarding the value of queen-bees, I have given some of my ideas on the subject, and if I am mistaken I trust some one will show me wherein the errors exist.

Naturally, most criticisms have been directed against the A. L. Root Co., and personally it is of course no one else's business how they advertise: but from another viewpoint their extensive business interests place them in a position in which they are expected to represent all that is good, practical and progressive. If they were not so, their acts become a proper subject for public discussion, especially as by imitation these acts become much more far-reaching than would seem possible at a first glance.

Custom has made $5.00 the standard selling price for a "Queen Breeder," and this is regarded as a very high value, greatly with the seller. For instance, I last spring purchased one from a man who gave me a pedigree for two generations, and the honey-yield of herself, her mother, and her grandmother, and also indicated where the strain originated. On the other hand, a New York breeder sold me one before fruit-bloom this season, and said she emerged last August (last year being the worst in 33 in this State). I therefore greatly restricting the opportunity for determining her value as a worker-mother, let alone a queen-mother. I am merely pointing out the variation, as I have no fault to find, for I think the buyer of such queens will average fully as much satisfaction and return for his money as buyers of other breeds and that breeders would do well to consider these points.

I have always thought bee-keeping quite a sad, conservative and dignified calling, far removed from those expensive avocations which are indulged in solely as recreations. I have felt that the bee-keeper usually applies the same amount of business-like common sense to his work as he does to his regular calling, whereas the ha'penny, or he who is in search of recreation only, tries to get away from his business and commonly fails to make a financial success of his bee-keeping. The future of bee-keeping may depend on what is now being done, and if we are to continue to advance, perhaps slowly but steadily, it is well for all to look to it that they do nothing that will have a tendency to make bee-keeping an any branch of it a matter of sad, or to allow our bee-papers to make any approach towards yellow journalism.

By their $200 valuation the Roots have obtained a great deal of free advertising, but as this has been largely by
adverse comment it is doubtful if it has paid well, and I hardly believe they knowingly used this valuation for the purposes of the business, and American Bee Journal for June 20, Mr. Doolittle gave us some figures, but as he failed to notice that the mother of the drone with which a queen mate is entitled to probably the same share in the results as the queen's mother, and also that the mother or mother's mate of the drones, the daughters mate, are also entitled to some share, his figures are of little value. Some years ago I tried to estimate the profit and loss in the case of horses, by the returns and expenses, but I gave up the attempt as a bad job, and I think the same fate will follow such estimates regarding bees. Possibly some one who is capable of compiling insurance statistics could help us out.

In regard to this matter, I believe the Roots are primarily guided by the best interests of the queen, and if the assumption is made that the best queen is valued as high as $50, I am not entirely convinced that the worst to be "best breeders." Now, I believe that a "best breeder" values the average queen, but it seems to me that if Mr. Doolittle's contention that only one queen in four is equal to her mother (and I see no good reason to doubt such a statement), and it is evident that where a queen is inferior it shows a lack of progression, and that the offspring are likely to keep on retrograding, it would seem that there is a great tendency towards a lottery in the scale of prices. In the case of prices he has guaranteed on all queens sold for higher prices than best-breeder rates, so that by returning a queen the purchaser could get his money back, for, if Mr. Doolittle's experience is real, only one man in four will get thorough satisfaction.

As to the scale of prices, I have puzzled over it without any satisfactory results at all. Will not some one please tell me how you work it out? This is all I can get.

A queen giving bees of .19 tongue length is worth...10

(a $5 increase)............................................ 15

A queen giving bees of .21 tongue length is worth...10 (an increase double the last or $10)................ 25

Therefore, a queen giving bees of .22 tongue length should be worth...10............................... 45 and it follows that a queen giving bees of .23 tongue length is worth...10............................... 85

That is to say, that the $200 queen is only worth $85, and her bees would have to have a tongue length between .22 and .23. How does that square with $250, which is $10 only? From which naturally follows the query, How can they afford to let them go at the advertised prices?

Allegeny Co., N. Y.

[Since the above was written, Editor Root has announced that his firm will hereafter place no values on breeders which they propose to keep and will not sell; therefore a portion of the above becomes inapplicable, but as "there are others" it is deemed best to publish the article in full as written. -- Editor.]

Brood in Sections—How to Avoid It.  

BY G. M. DOOLITTLE.

W hat is the cause of bees filling the sections with brood, and drone brood at that? What is the remedy for it? I put on one side the cases of arrangements or mistakes. I believe that the bees were crowded for room, and perhaps would be forced to swarm if the colony was split. I believe that the bees will fill the brood sections with drone brood. If you find any but drone-brood in the sections I should be surprised perhaps more than be, for I have yet to find worker-bee brood in sections, unless the colony was a new one and commenced their building "upstairs," when the term is sometimes the case where sections filled with foundation are placed on the hive when the swarm is first run in, with nothing but starters or empty frames below. When swarms are hived on empty frames, the sections should not be put on till the bees get...
well started at comb-building below—say in three or four days after the swarm is hived, unless a queen-excluder is used between the frames and the surplus arrangement. But where frames of comb are filled and foundation used are placed, the comb-building is the same. The questioner has the advantage of the present time, the questioner has restricted the drone-comb to the worker-comb, the natural consequence would be drone-comb in the sections. If the bees were allowed to build combs in the drone-comb before the honey is gathered, especially so with a light flow of honey and plenty of pollen; for at such times the bees rear large quantities of brood, and prepare for swarming by starting as much drone-comb as possible, the same being limited only by the amount of brood a queen in the small queens can produce. But there had little below the bees were all the more incentive for them to occupy that being built in the sections.

Having spoken of the cause we will now proceed to the remedy. There are two ways to remedy this matter. One is the one which I use most is the filling of the sections with very thin section foundation. This keeps all drone-comb out of the sections, and where there is no drone-comb there will be no drone-combrood, providing we have a good prolific queen; consequently this trouble with brood in the sections is remedied by thus using sections full of foundation having the worker-size of cells. Then, by thus using sections filled with worker foundation, we have very much more information, and I have no doubt that the sections are finished by the bees, for the capped combs having the worker-size of cells are much more beautiful to look at than those of the drone size, as all have compared the two and by putting up to an advantage.

The other plan of keeping the queen from the sections is by the use of the queen-excluding honey-board between the sections and the brood-chamber. This will effectively prevent brood in the sections at any time, and all times, as such honey-boards are quite expensive, both in time of putting on and taking from the hive; room for storage when not on the hive, as well as in the money used in the purchase, or of the material from which to make: for they do not do away with the bee-leaves, and if requisite the unsewed product, unless the sections are filled with foundation; besides, many claims that they should not be used in any event, on account of the believed lessened amount of our honey crowns in the amount of bees being lost to pass freely through the perforated metal. Regarding this latter claim I have my doubts as to its correctness, but consider all of the others as important.

If I have given the remedy, shall be done where we find brood in the sections before we know of, or have applied, the remedy or preventative? This all depends upon what stage the brood is in when we find it. If it is found before any of the brood is sealed over, we have little waste except in the time in taking the foundation from the section and putting them back on the hive again, for it is well known, that, if this unsealed brood is taken from the bees and kept in a cold place for a week, the same is dead, and such dead brood will be removed by the bees as soon as they have access to it. My plan used to be, before I learned of the prevention as given above, to take sections, found with eggs and unsealed larvae in them, to the cellar, and there leave them four or five days, when they were returned to the hive again, and if the queen disnot deposit more eggs in them, they were filled with honey, and when finished were as good as if no brood had been in them.

If the brood in the sections has been sealed long enough, before we knew of, or have applied the remedy, then the best thing to do is to cut the comb, or that portion having brood in it, from the sections, for honey stored in combs having cocoons in the cells is not just the thing for table use, nor to put on the market, unless this honey is separated from the combs by the use of the extractor, even though the same be sold as a second or third grade of comb honey, which would have to be if sold at all, on account of the market, it is a waste of labor to put honey on the market that will tend to injure the same, as is always the case by putting on honey of very inferior quality.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last.

No. 4. Some Reminiscences of an Old Bee-Keeper.

By THADDEUS SMITH.
Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names, and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of savings. We have by our premiums and sales to our subscribers, a large surplus, which we are going to send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of $1.00 for Wood Binder, we will mail you a Wood Binder free—if you will mention it.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Uniting Colonies in the Fall.

I have more colonies of bees than I care to winter, and there is no very ready sale for them here. What is the best way to dispose of the bees and secure the honey? When is the proper time in the season for doing it?

NEW BRUNSWICK.

ANSWER.—Perhaps as good a way as any is to unite colonies from time to time, and in the margin of colonies standing close together. A day or two before uniting kill the poorer queen of the two, and unite on the stand of the living queen. As the preserving is now being done, it may be done at once, unless you are likely to have a good fall crop, in which case unite about the beginning of the fall flow.

Bees that Fought and Killed Each Other.

Yesterday (July 7) one of my colonies cast a swarm. I was at church at the time (it being Sunday), and one of the boys hived it, and left the hive where they clustered. When I came home, an hour or so later, I put the hive on the stand where it was to be preserved. A little while afterwards I noticed quite a few bees flying where the swarm had clustered. I took an empty hive and comb and set it where the bees were flying, and in a short time I had them all on that comb—a quarrel of bees. I left it, and the bees were, in front of the entrance of the swarm, and all went in nicely. Shortly after this they commenced killing each other until there were about a quart of dead bees in front of the hive. I gave them a good smoking, and they seemed to quiet down. At this writing all seems to be pacificable. What was this fighting and killing each other?

S. DAKOTA.

ANSWER.—I don’t know. It is possible that the quart or so of bees were a small second swarm, and having a virgin queen were not kindly received. Of course, all would be pacificable under that presumption after all the bees of the second swarm were killed.

Diseased Bees.

1. I put about 20 colonies of bees into winter quarters last fall, and all but one were apparently in a healthy condition, and about half of these died during the winter and spring. A large percent of the bees died in this section, some losing every one of the extent of colonies in uniting, other things being equal uniting two colonies standing close together. A day or two before uniting kill the poorer queen of the two, and unite on the stand of the living queen. As the preserving is now being done, it may be done at once, unless you are likely to have a good fall crop, in which case unite about the beginning of the fall flow.

through these hives, that dead larvae are scattered throughout other frames, and one colony is bad enough to interfere with the increase of the colony. From one of my hives that was so bad that scarcely a bee was hatching, while all the frames were filled with brood and eggs. I removed the frames, giving empty combs, and in two days introduced a new queen, and now (about three weeks) there are no signs of disease.

How would you treat the strong colonies? Some are very strong, covering 20 Langstroth frames, and have two 20-pound supers nearly full. I have plenty of empty combs, as I run two or three extra hives.

What can I do with the frames of brood and honey taken from the diseased colonies? They are all wired and built on foundation, except the five new ones, and only three of these are affected.

What do you think this disease is, that would make its appearance in every colony at once.

Do you think the weather started it, and then it became contagious? I have never known such brood in this locality.

I have not been able to get any odor from the cases. When first noticed, the larva is about one-third grown, some looking a soft, greasy white, and some a yellowish white, and later turns brown. Dry up in the cell—some before, some after the lengthwise.

2. Do you think these colonies can be used another year by placing them under water in a current?

MASSACHUSETTS.

Answers.—I am afraid there is disease among your bees, which, although now apparently overcome while the honey-flow is on, may occur in the future. In the meantime it will be advisable for you to get all the literature you can on the subject, especially the leaflet on pickled brood, and back numbers of this journal relating to diseases of bees, and being thus informed upon the subject you can form a better judgment of the case than can one at a distance.

2. Placing diseased combs under running water would not be likely to do any good.

Storing in the Brood-Nest—Swarming Out.

1. In the months of November and December here the queen greatly diminishes her egg-laying, and the bees filled up nearly every comb with honey. If extracted, the bees store in honey all the same, and very little brood would be kept up. This greatly reduces the force of the colony. What must I do to prevent the storing honey in the brood-nest in such season of the year?

2. When my colonies swarm I destroy all queen-cells and turn back the swarm (with the exception of the queen, which I give to some queenless colony). A few days after I destroy the remaining colonies, such colonies now being without queen or cells. About two weeks after I give them a cell each: every one of the colonies swarmed out with the virgin queen. What must I do to prevent such swarming?

JAMAICA.

Answers.—1. It is not easy to prevent the bees from filling the combs with honey. Ha. Ha. If we could get some young queens will help. If you give empty frames or foundation it will give the queen a better chance to get in her work.

2. Instead of destroying all cells and then giving another cell two weeks later, if you leave one cell—or if you want to get the bees to come from chocolate give it at the same time you kill the cells—you will not be likely to have so much trouble with the bees swarming out. With your present plan there is no brood, or at the most a very little sealed brood, in the hive, and when the queen goes out on her wedding-trip the bees are along.

Bait-Sections—Extracting, Etc.

1. I have the ideal super and sections; some have been on my five hives over two months, but the bees have not yet worked in them at all. The frames are irregularly filled, average two-thirds; 8-frame hives. The books say bait with old or used section-boxes, but I am a beginner, and they are no fit, if that makes any difference to bees.

2. How can I extract honey from comb without an extractor? It could not always have been done with those machines. I scrape out the honey and comb together with a tablespoon, on each side of the foundation, cut it into a dish or pan, and separate it as we eat it. I want to put it into jars.

3. In the way, the foundation goes to pieces in scraping, though I use great care; some breaks in carrying to the house, about 20 steps. I use what is called in catalogs "medium brood foundation." I am told it ought to remain good in the frame at least eight years. CALIFORNIA.

Answers.—1. So long as the brood-frames do not average being more than two-thirds filled, you hardly ought to expect bees to do much in sections. Indeed, without any bait in supers you ought not to expect them to make any start at all until the brood-chamber is filled, and even with bait, you will find great difference in the super to the bait alone until they have more honey than they can get into the brood-chamber. You need not be thwarted in the matter of bait because you have no partly filled sections of the right size on hand. If you can get sections of another size, cut out the comb and fasten it into one of your sections. You may even cut a piece of comb with brood in it out of a brood-frame and fasten it in a section for bait. It will not make a desirable section when completed, but nothing can be more seductive to the bees in the way of bait.

2. I don't know of any way by which you can get honey out of a comb without an extractor that will leave the comb intact, unless it be to let the bees empty it.

If I understand you rightly, when you are scraping the honey away from the septum the latter gives way. Foundation may become dry and brittle through age, but after such foundation is put in use by the bees I doubt its being specially different from other. It is probably not so much brittleness as tenderness of which you complain, and the freshest foundation would have the same fault, the natural comb being still worse.

Honey-Plant Questions.

1. Is yellow sweet clover better than white for bees?

2. Is crimson clover good for bees? Does it bloom the first year?

3. When is the best time to sow either?

4. Does clover bloom the first year? If so, about what time of the year does it bloom?

SUBSCRIBER.

Answer.—1. I don't know. Although I have sowed some years it can not blossom before next year, and there is such a terrible drought that none of it may be alive. It would be of interest if the readers of this journal, who have had both white and yellow sweet clover, would give us some idea of their relative merits.

2. It is a fine honey-plant. It is usually sown late in summer, blooming the next season before white or red clover. If sown early in spring, some of it may blossom the same season.

3. The sweet clover about the time of sowing oats in spring : crimson clover in August. Sweet clover may also be sown in the early fall.

4. Cleome Integrifolia, or Rocky Mountain bee-plant. If I am not mistaken, blooms the first year toward the latter part of summer.

Cleaning a Mice-Infested Hive.

Can a hive be cleaned that has been infested with mice? If so, how?

WISCONSIN.

Answer.—If you mean the combs, the bees will clean them up. If the hive is infested with mice, use some medicine.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hammer." We can furnish a single copy postpaid for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at $1.00.

Please send us Names of Bee-Keeper's who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.
We have seen that influences towards truth-telling, self-control, selflessness—the blessed trio of human virtues—must work for a hearing at the very cradle. So the end of the few days of heat and summer weather, in thousands of our American homes—experiences which force their unwelcome presence—to darken the lives and hearts of bereaved parents over and over with the years, shows that the slender, delicate little bodies, even from the mind and soul, need a first thought in these early, fragilie months. So many of the little souls that fleck the sea of infancy flounder and are lost to all influence and usefulness in the world.

The baby is full of most sensitive nerves. Every one of these seems to reach to the surface, earth seems to touch it. If one is pinched, all cringe. So ready and active is this sympathy, that a toothpick or a lunch which the digested machinery fails to reach, brings the spasm, or the fatal bowel complaint. Almost before we know it the little craft has been washed beneath the waters, and we are left hopeless to mourn our terrible loss.

The very functional sympathy just referred to makes it all the critical stage of life, and explains the mortality which is so startling at this period. Paul’s words are so emphatically and peculiarly true. If one member suffers, all the members suffer with it. A fall from a chair, which one older would scarce notice, brings the spasm, and, mayhaps, death. The cutting of the cord by those who have proved a pinprick, now blocks the stomach and brings the fatal bowel complaint. A change of food that later will come with refreshment, now smotheres digestion and limits the life.

The excitement of too much talk may make the children’s eyes cringe. Their admiring friends, which with more of age would be all invigorating and life-giving, now weary the energies flag, and the bodily functions, tired out, cease their action.

We must ever remember that infancy is the critical age; that the very sympathy between the organs is a menace to life itself. Teething, which comes at its first year-mark, is ever to be dreaded. The heat of summer is full of menace. Change of place and companions at this susceptible age is too stimulating, and fraught with danger. Change of food is often the very last straw, and the back severs. Combine all these, and what wonder that the fragile little craft goes to the bottom?

It may be wise to leave home in summer. This is vacation time. But if a baby adorns our home and gladdens our arteries, better think twice, especially if at about the year-date when the great molar is trying to push through. Then if we must go, we must seek a cooler place, a quiet nook, and plan that there be no change in the food. Often the change is from country to city, to the dear old home friends, who rightly appreciate the little walf as a very treasure, and the nerves are waked and going till excitement and exhaustion have done their work. Usually the food is changed perforce, and with the heat, excitement, change, enforced by the offending molar, the latter is too numinous and strong, and the story is brief. The wise, thoughtful parents will see that the little jewel which gives charm to the home and life is too rare and precious to permit even vacation pleasure and change to bring threatening dangers. They will forego even the old home for baby’s sake. They will plan with all the astuteness of love to minimize the dangers that menace infancy, and will gladly forego the change or visit—even the rare, gracious pleasure of reviving the gladsmess of life of the old home, for the sake of the life and health of the blessed baby.

Catnip Seed Free!

We have a small quantity of Catnip Seed which we wish to offer our readers. Some consider catnip one of the greatest of honey-yielders. We will mail to one of our regular subscribers one ounce of the seed for forwarding as ONE NEW subscriber to the American Bee Journal for a year with $1.00; or will mail to any one an ounce of the seed and the American Bee Journal for the other year—both for $1.30; or will mail an ounce of the seed alone for 50 cents. As our stock of this seed is very small, better order soon.

The Home Circle.

Conducted by Prof. A. J. Cook, Claremont, Calif.

THE BABY.
What is the little one thinking about?
Very wonderful things—no doubt.
Yet he laughs and cries, and cats and drinks,
And chuckles androws, and nods and winks.
As if his head were so full of curiosities
And curious riddles as any sphinx!
Warped by colic and wet by tears.
Mutilated, bruised and tortured by tears;
Our little nephews will lose two years;
And he'll never know
Where the sombre groves.
He needn't laugh for he'll find it so!

This is from the genial pen of that wholesome writer, Dr. J. G. Holland. I would have his books grace the table of all our home circles. "Boy Path" and his other stories are always inspiring, and inspire our young people to pure thought and purpose. The poem from which the above is taken is so full of humor, of unflagging interest, of real philosophy, that all our children and young people may well read—_the children portions of it, and the older ones all of it_. Like Job, it discloses the problem of evil, and will help to get a philosophy of life and thought that can not come too early into the heart and life.

I hope all our mothers will see that "Bliter Sweety" is among the volumes that the children prize as among their best belongings. The author of this poem is "Kathrina," and "Timothy Ticitom's Letters to Young People"—all by the same author. All are good to read with the children; all will develop in pure wholesome lines; all will invigorate, and give a start-off from a right, true foundation.

But we have almost forgotten the baby. Luther said he loved and felt awed before the baby. For in early baby is the promise of so much of good or evil. Every infant is potentially so pure, true and noble, or so base, depraved, and ignoble, that we wonder we are allowed to start the very cradle to start the little craft in best courses, that baby, mind and soul, may all trend towards the fairest port. The poem further traces the little craft—

_Out from the shore of the great unknown,
Blind and wailing, and alone._

Into the light of day,
Out from the shore of the unknown sea.

Tossing in pitable agony.

Of the unknown sea that reeks and roils,
Speckled with the marks of little souls,

Barebacks benumbed on the other side,
And slipped from heaven on an ebbing tide.

And how beautiful this reference to the mother:

_What does he think when her quick embrace
Presses his hand and buries his face,
Deep where the heart-throbs sink and swell,
With a tenderness she can never tell,_

Though she murmurs the words
Of all the birds—

Words she has learned to murmur well.

To Our Shippers:

We were obliged to notify you a few weeks ago that one Joseph M. McCaul had leased our old quarters at Nos. 120-122 West Broadway, New York City, and had there started up business under the name "Hildreth, McCaul Co.," and had distributed a multitude of circulars so worded as to create the impression that his business was a successor to or a branch of the business of Hildreth & Segelken.

For the protection of our shippers and ourselves, we at once instructed our attorney to commence action to enjoin the said McCaul from using the name Hildreth in any manner whatsoever in connection with his business. On the 10th day of July, 1901, Hon. David McAdam, Justice of the Supreme Court of the State of New York, after a full argument upon the merits, issued a peremptory injunction, of which the following is an extract:

"And it appearing that the plaintiffs have for a long time been and now are carrying on business under the style of 'Hildreth & Segelken,' and that the defendant has recently opened a business at 120-122 West Broadway, in the Borough of Manhattan, City of New York, and is carrying on the same under the style of 'Hildreth, McCaul Co.,' and that such act is in violation of the plaintiffs' rights, and that the commission or continuance thereof, during the pendency of this action will produce irreparable injury to the plaintiffs; it is

ORDERED that the defendant (Joseph M. McCaul) and each of his agents, servants and employees and all other persons acting under his authority and direction be, and he and they are hereby restrained and enjoined from showing, displaying or otherwise using during the pendency of this action in or upon any papers, devices, sign or signs, or otherwise, in the business conducted by the defendant at No. 120-122 West Broadway, in the Borough of Manhattan, City of New York, or elsewhere the name of "Hildreth" separately or conjunctively with any other name, designation or description."

Outside of our desire in our own interests to protect the name which we have built by years of satisfactory dealings with our customers, we hastened to procure this injunction as soon as possible, to prevent our shippers from being misled into sending their goods to one who would make an attempt to gain their trade by such a trick and device.

With thanks for the many expressions of good-will we have received from our shippers concerning this attempt to trade under our name, we are,

Sincerely yours,

HILDRETH & SEGELKEN,

265-267 Greenwich Street, NEW YORK, N. Y.

For sending us One New Subscriber for one year, to the American Bee Journal, with $1.00, we will send, by return mail, a fine Untested Italian Queen free. This offer is made only to our present regular subscribers.

GEORGE W. YORK & CO.

We will mail one of the above queens alone for 75 cents; or 3 for $2.10.

Please do not conflict the above offer with the one on another page which refers to Red Clover Queens. For sending us one new subscriber at $1.00, and 25cts., we will mail you free an Untested Red Clover Italian Queen.

UNTESTED  
ITALIAN QUEENS FREE.

Breed from the Best.

A Stray Straw in Gleninnes in Bee-Culture says:
The antique queen-rearing requires careful selection of sire and dam, adapting one to the other. Little can be done at that till foundation, but in the meantime, if every bee-keeper persistently breeds from queens whose colonies store biggest crops, I’m sure we shall have something to talk about — Yes, that is true, J. F. McGuire of California has a row of hives in his apiary, each of which has a queen of his very best breed. He says it is easy to see that this row of hives gives a larger yield than any other row of an equal number or strength.—EDITOR.

Bees as Fertilizers.

Some testimony has been given to show that bees may be dispensed with as fertilizers of fruit-bloom. J. W. Rose gives in the Progressive Bee-Keeper some testimony on the other side, as follows:

We made some experiments during fruit-bloom with our bees by covering the limbs that would bloom of pear, plum and damson trees, and had intended also to experiment on apple-bloom, but I was away from home when they began blooming, so didn’t get to work on them. Contrary to expectation, on peach-bloom there were some peaches that set, but not quite so many per plant as on limbs with bloom uncovered. We also noticed more dwarfed fruit on the covered limbs than on those not covered, that course not mature. We made a new trial—setting, on the pear, plum and damson limbs covered, there was not a single fruit set, so we conclude that bees help the peach same, any way, and that they, or some other insect, are necessary for pears and plums.

Brood in Sections.

Some producers of comb honey find no need of queen-excluders, while others find them necessary. Referring to a Stray Straw in Gleninnes in Bee-Culture says:

Complaint is made by some that, when no queen-excluder is used the queen goes up and lays in the sections. The curious part is, that A says he has no trouble at all, while B has brood in a fourth of his beehives. Possibly this explains it: There is no drone-comb in the brood-chamber in either case. If bees have only started to the sections, and will build drone-comb there, and the queen will come up to lay where the drone-comb is. A’s sections are filled with worker foundation, and there will be no drone-comb there to bat the queen up.—In California, so far as I have been able to find, the bee-keeper uses the queen to help the comb. The little bees seem to be generally used, even for comb honey.—EDITOR.

Prevention of Swarming.

H. D. Burrell uses the Heddron hive, and gives in the Bee-Keeper’s Review this method of preventing swarming, which, with some modifications, he thinks would work with other hives. He says:

Eight frames are fastened in a case, and any desired number of cases may be used for a brood-chamber. I usually use two, which gives a horizontal field entirely through the middle of the brood-chamber. This bee-space is a fine place to build queen-cells in, and if the bees are preparing to swarm, quee
AMERICAN BEE JOURNAL

QUEENS

QUIRIN The Queen-Breeder—has now on hand, ready to sell, 500 young, long-tongued Red Clover Queens, Golden or Leather Colored.

We have one of Root's best breeders from his $290, long-tongued, Red Clover Queen, and a Golden Breeder which we are told is worth $100, if there is a queen in the U. S. worth that sum.

J. L. Gandy, of Howoldt, Nebr., tells us that the colonies having one of our queens, stored over 400 pounds mostly comb honey in a single season.

A. I. Root's folks say that our queens are extra fine, too, and the editor of the American Bee Journal tells us that he has good reports from our stock from time to time.

We have years of experience in mailing and rearing Queens. Use yours presently by return mail from now on. Prices for balance of season as follows:

<table>
<thead>
<tr>
<th>Selected</th>
<th>$1.25</th>
<th>50 Queen</th>
<th>$10.00</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tested</td>
<td>$1.50</td>
<td>100 Queen</td>
<td>$25.00</td>
</tr>
</tbody>
</table>

Divide the surplus cases between the two hives, and give more surplus room if it seems necessary. A small yard that is likely to swarm in the same way.

If convenient to look at the hives just before dark, it is easy to tell where the queen sits. The queenless bees will be uneasy, and crawling about the front of the hive, apparently hunting for their queen. If it should appear that she is in the comb, move it to the old stand, exchange places with the removed part. By moving the queenlessness will not be at all noticeable, unless the queen removed from the former stand, as most of the field-bees will return to the old home, although this is not always essential.

The weakening of the colonies, and the additional room given, will almost always cure them of the swarming fever.

At the end of the season, each hive can be used as the parent of four or five other colonies, and at the end of the season two or three hives in one side. This small colony may be used for strengthening a weak colony, as a nucleus for queen-rearing, for increase of colonies, or for a surplus case on any hive in the yard.

Bait-Sections:

I was glad to see Mr. Doolittle standing up so staunchly for these. Several eminent beekeepers some time ago contended that they were of little use, and would not stand into way. I would have every single unfinished section carefully preserved, and a number placed to every frame. But I would have them all nicely cleaned up by the bees before storing them away, as I fear any gummed-up or folded-up section. They might well be assimilated to a sort of "infection," and granulate the new crop stored in them. This seems to be a most pernicious fault, and I would consider all cases of construction or backup. -British Bee Journal.

Prolong Lives of Best Queens.

Says a Stray Swarmer in Gleanings in Bee-Culture:

Lounging in bees is coming to the front. Assuming that in harvest time a worker lives six weeks, and goes abroad if 16 days old, if its life were extended it could store 27 percent more. If one queen lives twice as long as another, will not her workers live at least a little longer? If it is possible, by proper selection continuously exercised, we might add to that work to the life of the worker. I then think that the queen's life, long the summer life, that ought to add sixth to its winter life. In that case, a bee born May 1, which now lives till December 31, might get quite a help in the wintering problem.

Another thing: We can tell better what a queen is by two tests. One is made with work bees we can by a single season's work. The one that shows herself best for three seasons is a safe one to breed from, and I have found that in doing the work that a queen born in 1897 that are among the best—one of them, I think, the very best I have. While this is true, the average, even, I think, would be better displaced in two years by a young one. —Editor.

Mulberries and Bees.

It may not have occurred to some of your readers what a remarkable honey-plant they may have, right at their doors, irrespective of locality.

In the coldest habitable region the white or Russian mulberry may be depended on to thrive. In the heat of the South it flourishes and supplies abundant shade. In the more temperate climates, especially its native home, the Mulberry has adapted itself to the growth of the bee in its various forms, both as a food and a home.

It is a fact well known to beekeepers that no one need fear failure. It is easily propagated from seed, and cuttings take root in moist soil as readily as willows, attaining a height of 60 to 100 feet, and girth of trunk from one to two feet in diameter. Planted a foot or two apart it affords an attractive hedge-fence, as effective as the osage orange.

The availability of the mulberry for shade, post-clubs, and firewood is also a temptation to sensible farmers. Though a comparatively soft wood, it is of tough fiber, successfully resisting the force of the winds when left to yield trees break off. Its far-reaching roots are great foragers for this tree’s sustenance and anchorage. The fruit is a creamy-white, and so sweet (77 percent sugar) that one must acquire a taste for its enjoyment. Not least of its virtues is the ease of its harvest. Simplicity a sheet under the tree and shake well to bring its luscious fruit. No sugar is required for their preparation for the table. Milk, cream, or jam, will greatly improve their delicacy. Made into jam, no fruit is healthier, more cheaply prepared, nutritious, or more relished by young or old who are fond of natural sweets. I can only liken the berry to a vegetable honey, so pure its flavor and agreeable its sweetness.

To touch upon the economic value of mulberry leaves in fostering the culture of silk industries is ancient history. The Egyptians, the old Greeks, the Romans and their descendents have profited through careful attention to this vegetable boon of Nature.

I intend simply to suggest as a result of my personal experience, that its ripe berries are many times pulped upon by the bee as they would a broken comb of honey. The manner of feeding is exceedingly simple. I crush the ripe white mulberry and convenient dish and with a piece of shingle, large spoon or any light carrier readily at hand, I place a quantity of the berry quantity upon their alighting-board. The bees will naturally investigate for some minutes, but when they have tasted the sweet juice, the bee carrier seems to possess them to completely cover the mass, and extract every vestige of its sweetness.

It is possible that here we may glean a hint that will in future generations forestall the almost complete honey failure of the last few years, and bring our industry back into the channels of success and profit.

Cook Co., Ill.

Dr. Perio.

[The Doctor brought to us a sample of the mulberries, and we fed it to our bees after the crushing. Well, they just carried it in sick and clean from the alighting-board in double quick time. We should like, to taste the flavor of the honey produced from mulberries.]

An Swarming Experience.

I do not know that I can give the explanation asked by Dr. F. C. Hooper, of page 290, concerning the use of sugar in any better way than to give you a part of my swarming record for this year.

Swarms issued: No. 23, May 30, hired in No. 15; No. 16, May 30; No. 25, July 7.

You will see by this that my new or prime swarm cast a swarm, as most of my new or prime swarms do, and that the parent colony...

Tennessee Queens! Fine lot of Choice Tested Queens reared last season, daughters of select improved and select golden queens, reared 1/2 mile apart, and mated to select drones, $1.50 each; standard or Queens, from same breeders, either strain, 75c each. No bees owned nearer than 3 miles. None impure within 3, and free within 5 miles. 2 years' experience. Discount on large orders. Contracts with dealers a specialty. JOHN M. DAVIS, Spring Hill, Tenn.

Bees Doing Fine—Alalfa. Bees are doing fine. I send a sample of honey. Please let me know what it was gathered from, as we are unable to find out the exact results of the bees. I think they must have gone a long distance. I rather think it is alalfa honey, as the farmers are beginning to sow it here. The honey for this season, which was gathered early morning until late, and seems to be the only ones that are not complaining of the heat and drought. The honey for the last two weeks has been from 29 to 102, the last two weeks.

Woodbury Co., Iowa, July 20.

The sample of honey has the color and flavor of alfalfa honey. Of course all you can like it, as such honey never need wait long for a buyer.—EDITOR.

Good White Clover Flow. The white clover honey-flow has been unusually good, but is probably at an end. From 35 colonies, spring count, and an increase of 20, I have harvested six sections, and there are on the hives some 2000 sections, most of which are full, besides some half dozen extra-honey supers. I have a few colonies that have produced upward of 150 sections, and three or four have done still better than that.
F. W. HALL.

SIOUX CO., IOWA, JULY 22.

TOO HOT AND TOO DRY. We are suffering with heat and drought here. I had 21 colonies of bees, spring count, and have 30 at present in fine condition. My crop of white honey will not exceed 400 pounds, and there is no sign of rain, consequently we cannot expect a full crop; but I must have my American Bee Journal.

MRS. PAUL BARRETT.
Crawford Co., Wis., July 19.

Another Honey Crop Failure. I am sorry to have to report another failure of the honey crop. It seems as if there would be nothing this fall, either, in the way of honey, for our fields are parched. The corn is tasseling out without any prospect of ears, and the crop of weevils, which are generally luxuriant at this season, only serve to make bad off as the more valuable plants. This is probably one of the worst drouths ever seen in this section.

C. F. DIJANT.
Hamilton Co., Ill., July 19.

Hot, Dry Weather. We had a good start of white clover honey, but the hot, dry weather has nearly finished it. The Basswood view is but little changed; it is so very dry but little can be expected from heartsease and buckwheat.

Linn Co., Iowa, July 13.

Don't Report Glowingly or Too Soon. There is a report from this county (Marshall), in a recent number of the American Bee Journal, from J. W. Sanders. He says that we are having the honey crop that we would have had in the State. Now, I have not found it so. We had a few days that were extra good, but the dry weather hindering compliance with the order. The wind killed the clover, and made what little basswood bloom there was barren of nectar. I consider that my crop was cut one-half from...
BEE-BOOKS

Advanced Bee-Culture, Its Methods and Man-
gement, by W. Z. Hutchinson. The author of this book is a practical and experienced

Rational Bee-Keeping, by Dr. John Drrien.
This is a translation of the latest German
book on bee-culture. It has 250 pages, bound in paper, and prices, $1.40.

Bien-Kultur, by Thos. G. Newman. This
is a German translation of the principal portion
of the book called "Bee and Honey." 110-page
pamphlet. Price, 20 cents.

Bienzucht und Honiggewinnung, nach der neuen
methode von Dr. G. Eggers. Anyone who is interested in bee-keeping will find
this book gives the latest and most approved methods of bee-keeping in an easy, comprehen-
sive style, with illustrations to suit the subject. 50 pages, bound cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H.
Bracken. A book designed for the use of the casual reader and the amateur bee-keeper.
Price, 50 cents.

Bee-Keeping for Profit, by Dr. G. L. Tinker. Re-
vised and enlarged. It details the author's "system of bee-keeping," by which huge yields of
honey and comb are obtained. Price, 80 pages, illustrated. Price, $1.25.

Apairy Register, by Thomas G. Newman. Devotes
two pages to a colony. Leather binding.
Price, 25 cents for 50 colonies; 25¢ for 100
colonies, $1.25.

Dr. Howard's Book on Foul Brood.—Gives the
McGee Treatment and reviews the experi-
ments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R.
Pfeiffer. Result of 25 years experience. 20 pages.

Foul Brood Treatment, by Prof. F. R. Chor-

Foul Brood, by A. R. Kohnecke. Origin, De-
velopment and Cure. Price, 10 cents.

Cappings and Packets, by Dr. Sawyer, Fanny Field,
and others. Illustrated. All about cap-
ing honey. How to make the most money in
comb. Price, 50 cents.

Our Poultry Doctor, or Health in the Poultry
Yard and How to Cure Sick Fowls, by Fanny Field. Every farmer should have this

Poultry for Market and Market Poultry for
Fanny Field. Published by the Fanny Field Poultry Business. 64 pages. Price, 20 cents.

1901—Bee-Keepers Supplies! We can furnish you with The A. L. Root Co's goods as wholesale or retail at their prices. We can save you freight, and also promptly. Market price M. H. HUNT & SON, Belch Bros, Waynec Co., Mich. Please mention Bee Journal when writing.

CHICAGO, July 18.—Choice white comb honey is arriving rather slowly from all quarters. There is no accumulation at this writing, as re-
sellers will sell within a week and get quite a number of them on the same day. Amber grades bring about 12c. Extracted dull and slow of sale at anything over 50 cents. No. 1 white at 3c good with demand. R. A. BURRETT & Co.

CINCINNATI, May 17.—No demand for comb honey, also stock of it well exhausted. Ex-
tracted dull,—10 to 12c, with no demand at all. Lower prices from 5c to 1c per pound.

BOSTON, June 23.—There is practically no com-
mercial comb honey, and demand for good white comb. Fancy stock sells readily at 1c; No. 1 white at 1.00c, and amber at 1.62c. Extracted not in much demand, with plenty of 60c extract. Price, in comb at 3.50c; in amber, 40c.

OMAHA, May 1.—Comb honey, extra white, 25c; 1000-lb. cases, per cwt., 1.40 cent.

PEYCEY BROS.

NEW YORK, July 8.—Our market is practically
bare of comb honey, and demand good for white comb. Fancy stock sells readily at 1c; No. 1 white at from 1.00c, and amber at 1.62c. Extracted not in much demand, with plenty of 60c extract. Price, in comb at 3.50c; in amber, 40c.

HILDEBRAND & SCHOBER.

ALABANY, N. Y., June 13.—Honey market is
dull with no receipts or stocks and little de-
mand. It is between seasons now. Prospect of some crop in this vicinity from what bees have
just left the nectar and honey very little call for it. There are no signs of farmer-keepers and plenty of large quantities of honey made by hive brood exterminators. H. R. WIGHT.

DETROIT, July 15.—Fancy white, 15c; No. 1, 1.00c; no dark to quote. Extracted, white, 60c; dark and amber, 50c to 60c.

M. H. HUNT & SON.

BUFFALO, July 16.—No demand for honey yet
undoubtedly because of our early season, or
perhaps 10c. Some old lots still about, un-
salable, almost, at 6c, and 8c. Bees wax, 22c.

BATTEN & CO.

KANSAS CITY, June 29.—Very little honey on the market at this time, while our 100-lb. comb-
granulated. Sales are light at 15 cents for best comb. C. C. B. Beeswax firm at 25630th.

W. H. CROWELL PRODUCE CO.
Successors to C. C. Clemens & Co.

SAN FRANCISCO, June 19.—White comb, 1.15c
12c; amber, 96c; dark, 68c. Extracted, white, 40c; amber, 33c; cocoa, 25c.

BEESWAX, 25c.

BEESWAX, 26c.

Market shows no quantulo improvement, but there are no large quantities obtainable at the prices generally named by dealers. In a small market, for instance, some of the city buyers, at higher prices than are quoted are being realized.

WANTED

Fancy White Comb Honey in co-op cases; also Ex-

Reference—German National Bank, Cincinnati.

More Bee-Keepers' Paradises...  

E. R. Root has just returned from a 6,000-mile trip through some of the best bee-locations in the world, and has already begun his series of write-ups, accompanied with fine photos, in Gleanings in Bee-Culture. The following editorial appears Aug. 1, and will give something of an idea of what he will describe:  

Some little time ago I promised to tell about the bee-keepers' paradise in Texas. I have this on the docket, and it will appear as I take up the line of my travels. But since running across that paradise I have run into two or three others. There is one west of the Rockies, in Colorado, that is not yet overstocked with bees or bee-keepers; another one in Central Idaho—in fact, I do not know but the whole State. These will be described in turn. The fact is, millions of capital are being invested in irrigation; irrigation means alfalfa; alfalfa means a paradise for bees. But I found all along my trip that alfalfa-growing preceded bee-keeping by two or three years, for it seems to take about that length of time before bee-keepers find these gold-mines that have been hitherto unoccupied.  

If you are dissatisfied with your present location, and for financial reasons, or on account of health, will be compelled to leave, subscribe for Gleanings in Bee-Culture, and learn something about the great South and the great West. There are many locations in the West that are not yet occupied—splendid bee-locations. If you wish to learn about them, send 25 cents for a six-months' trial subscription, or $1.00 for one year and one untested Italian queen. Or, send $2.00 and we will send Gleanings one year and one of our celebrated Red Clover Queens.  

THE A. I. ROOT CO., Medina, Ohio.

are headquarters for ROOT'S BEE-KEEPERS' SUPPLIES IN CHICAGO.  
Send to them for their free catalog.
A Superior Red Clover Queen

For sending us One New Subscriber and 25 cents ($1.25 in all)

We arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us this season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he uses is direct from Italy, having imported himself. Her worker-bees are large, some what leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

All queens guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

We would like each of our present readers to have one or more of these fine Queens. Simply send us the name and address of a new subscriber for the American Bee Journal for one year, and 25 cents extra, and the queen will be mailed to you. Our queen-rearer is now caught up with orders, and expects to be able to mail them hereafter within 48 hours after we receive the order. He is in another State, and we will send him the Queen orders as fast as we get them at this office.

He is prepared to rear and mail a large number.

The cash price of these Queens are $1.00 each: 3 for $2.70; or 6 for $5.00.

Send all orders to

GEORGE W. YORK & CO.,
144 & 146 Erie Street, CHICAGO, ILL.

The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only $1.40. It is a fine thing to present your own copy of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

EXECUTIVE COMMITTEE.

ERNST R. ROOST, President.
R. C. DINNING, Vice-President.
DR. A. B. MASON, Secretary, Toledo, Ohio.
EUGENE SECOR, General Manager and Treasurer, Forest City, Iowa.

The Novelty Pocket-Knife.

Your Name on the Knife—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your Pocket-Knife will serve as an identificant; and in case of death, your relatives will at once be notified of the accident.

How to obtain the Novelty Knife? We send it postpaid for $1.25, or give it as a Premium to the one sending in 25 cents. It is a Premium to every subscriber to the Bee Journal (with $5.00) and to the one sending in 25 cents.

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

For sending us One New Subscriber and 25 cents ($1.25 in all)

Queen-Clipping Device Free....

The Monette Queen-Clipping Device is a fine thing for use in catching and clipping Queens' wings. We mail it for 25 cents; or will add it as a Premium for sending us ONE NEW subscriber to the Bee Journal for a year at $1.00, or for $10. We will mail the Bee Journal one year and the Clipping Device. Address,

GEORGE W. YORK & CO.,
144 & 146 Erie Street, CHICAGO, ILL.
Editorial.

General vs. Special Knowledge.—The tendency nowadays is toward specialization. Even in bee-keeping there are special lines, and a man is likely to do his best when he confines himself within certain limits. But it is a serious mistake to think that one should strive longer, rather than better, within his line. It is not likely that any bee-keeper became so proficient in any one line without being pretty well informed in all other lines pertaining to bee-keeping. A good, all-around bee-keeper makes the best basis for a good specialist. Dr. Miller’s advice in another column is good. Inform yourself in advance, even upon subjects that you think may never have any interest for you. Study all of your text-book until it is familiar. Don’t omit a knowledge of the Dzierzon theory. Lay a solid foundation, and then when the time comes that knowledge upon any point is needed, it will be ready.

Northern vs. Southern Queens.—A wordy discussion upon this subject occurs in the Southland Queen between S. E. Miller and E. J. Atchley, which, if it proves nothing else, proves that men may have very different views. What one claims for the North the other claims for the South. Mr. Miller claims that people of a temperate climate are superior to those of a tropical climate in strength, hardness, industry, and otherwise, and that where a Northern and a Southern army meet on equal terms the Northern army is victorious. Mr. Atchley says late history proves that it takes ten Northern men to conquer one Southern man; that the men and women of the South, as a rule, are strong and robust, capable of enduring great hardships, and less subject to disease than those of the North; that Southern queens lay more and live longer, and the bees live longer, are more hardy, and gather more honey.

Feeding Back—Dr. Hutchinson in the Bee-Keepers’ Review gives some excellent hints. If the feeding is begun just as the flow from basswood is beginning to slack up, the work will go on apace, whereas every day’s delay after that time will make it necessary for the bees to fill up again in the brood-chamber. Contract to live Langstroth combs at the most. Three are better, but in that case there will be a weakened colony unless it is strengthened by adding to it cases of sections, bees and all, from other colonies. Add boiling water to the honey to be fed until it is thin as nectar. With 100 pounds of unfinished sections and 100 pounds of extracted honey, Mr. Hutchinson gets 100 pounds of finished sections. He says further:

Black bees do the best work; hybrids next; then comes the dark Italians. Light Italians do very poor work in feeding back.

There are two grades of them as regards their completion. Contract the brood-nests of the colonies that are to be employed. Not the cases of sections around, one on a hive, but not on the hives containing the colonies that are to be employed in feeding back. The bees will go up and occupy the sections. Now gather up the cases, bees and all, and put two cases on each hive. This is done to secure populous colonies, as they do the best work in feeding back. I have never had trouble from the bees quarreling. Put a case of nearly finished sections next to the brood-nest, and those that are not so nearly finished on top, and then the feeder.

Note the peculiarities of the different colonies. One will take down the feed and draw out the combs much better than will some of the others. Another colony will be a poor feeder, but will cap the honey much better than some other colonies will cap their honey. As the work progresses, and fewer colonies are needed, throw out those that do the poorest work.

A Putty-Knife as a Hive-Tool, to scrape propolis off the hives, pry frames apart with, and for scraping off burr-combs, is recommended in the Progressive Bee-keeper. “Somnambulist” suggests that a small trowel with the edges sharpened is hard to beat.

Moving Bees for Fall Flow.—An interesting discussion upon this topic at the Ontario convention is reported in the Canadian Bee Journal. Among the points brought out was one that even if no surplus is gained there may be pay for the trouble in the better supply of winter stores, and still further there may be a great advantage in the greater number of young bees to go into winter quarters.

It was urged that, although for spring and fall moving a large-sized entrance covered with wire-cloth may give sufficient ventilation, this will not do when moving to the backwet fields in hot weather. There should be a space of two inches over the brood-nest and four inches of wire-cloth over. Some preferred a hay-rack with a layer of hay without springs; others preferred heavy springs. A board platform may be used with common carpet tacks sprinkled over it. The tacks will sink into the platform and into the hive-bottoms, preventing the hives from sliding about.

To prevent trouble with a nervous driver in case any hives should spring a leak, mosquito net may cover the entire load. On a close, warm day, if bees begin to stick their tongues up through the wire-cloth, they should be well sprinkled with water. The bees will suffer less if hauled at night, or if the start be made in the middle of the night. Frames should run crosswise on the wagon. Some hauled the hives home late in the fall, putting them immediately in the cellar without opportunity for a flight, and found no bad results.

Alfalfa Honey,—although always of good flavor, says Editor Root, varies in color, in some seasons being light amber, and in others almost water-white.

Measuring Bees’ Tongues.—It has more than once been suggested that it is no safe criterion to judge the value of a working bee by mere length of tongue alone, because there may be a difference in the energy of two bees having tongues of the same length. This difference can be measured by the difference in the amount of stores gathered by two colonies. A. W. Wright, in gleanings in Bee-culture, proposes a more expeditious method of measuring this energy without taking all the bees of a colony. He has constructed an ingenious glossometer, which gives measurements to the thousandth of an inch, and says:

“The energy of the bees is clearly shown in their efforts to reach the candy. While some are easily discouraged, and give up without much effort, others will persevere, and work and stretch their tongues to the utmost limit; and when the candy is clearly beyond their reach they seem loath to yield.”

Mr. Wright perhaps is the first to suggest the advisability of measuring the capacity of the honey-sacs of different bees, in doing which only one bee must be taken at a time and allowed to fill its sac from a receptacle so small that the amount taken can be accurately determined. While in general larger honey-sacs go with longer tongues, two bees having tongues of the same length may have honey-sacs of different capacities. It is not hard to believe that a bee with a small honey-sac must make more journeys, hence consume more time, in storing a given amount, than one with a larger sac. He says that the living bee, when reaching for nectar, can protrude its tongue farther than the tongue of the dead bee can be stretched without rupture, and that the bees of a queen, if pure, differ but little from each other in tongue measure, capacity of the honey-sac, and working energy. Objection is made to using wire-cloth in a glossometer, as the apertures are by no means uniform in size or shape.

Width of Top-Bars of Extracting-Frames, Etc.
BY C. P. DADANT.

MR. DADANT:—I would be very much obliged to hear from you as to what width of top-bars you would advise to use when only 9 frames are in the ten-frame hive. Then another question: Which do you consider the best way to have combs in extracting frames cleaned by the bees when they are not to be used again the same season? Some shoveling back on the colonies, but frequently a good many bees remained in them, and again at the end of the season, within a few days. I was brought to this conclusion; but did not take it down in the broad-channel.—JACOB WAGNER.

In replying to these questions, I will refer the reader to an article previously written by me on page 452, on the spacing of extracting-frames, and the number of them to be used in a super.

The thickness and width of top-bars has influence, in only one particular, as far as I know, that is, it helps control the amount of barry or brace combs built by the bees. With a light top-bar, of narrow width, the bees will often build a great number of brace-combs, joining one comb with the other and filling every available space with honey. This makes the handling of the combs more or less inconvenient. When with a wide top-bar, the bees are giving up only the narrow space between the combs, and especially when the top-bar is also thick perpendicularly, there is much less brace-comb built.

But, in extracting, the wide top-bars have the great inconvenience of making it necessary to cut or take off the wax on the under side of the top-bar, until the combs are built out far enough to remedy this. Many of our friends prefer the ordinary narrow triangular top-bar for this very reason. In our own practice, we have used both the 1/2 top-bar and the 3/4, and we find very little difference in practical results. But, if the frames are kept as far apart as is necessary to secure thick combs, the bees will build brace-combs anyhow, even if we use wide and thick top-bars. But we do not find much inconvenience resulting from it, because we keep our bees sufficiently supplied with space to prevent them from building brace-combs. The latter are usually built when space is getting short in the super and seem to be the finishing touch which the bees give to their supers. If we forestall their aim, by adding more combs or by extracting, no brace-combs will be built. So, in our estimation, the width and thickness of the top-bar of extracting-combs is not of any particular importance.

CLEANING EXTRACTING-COMBS.

Concerning the giving back of the extracted combs to the bees to be cleaned at the end of the season, I am decidedly in favor of the affirmative. The question was discussed at length last spring in the International Review of Bee-Culture, of Switzerland. My readers well know that, over there, they produce extracted honey almost exclusively, and many different methods of accomplish. There seems to be about an equal division on the matter of returning the combs to the hives. But the advantages of the method, in my mind, very greatly overbalance the disadvantages.

It is held by those who are in favor of not returning the combs to the hives, that they are just as easily kept when sticky with honey; that it saves a great deal of trouble, and that when the supers are given to the bees in the spring, they work in them much more readily if these combs are rendered attractive by the honey sticking to them.

In the other hand, the combs which are left smeared with honey when put away for winter attract mice much more readily than if they have been thoroughly cleansed by the bees. Mice will make very little effort to enter a surplus case, if there is no smell but that of the wax; but if they can perceive the odor of honey they will take the pains to work their way in, for they are very fond of it. Whenever I have had combs damaged by the mice, I have almost invariably found them to be combs that contained honey, especially honey that was thick in flavor and odor.

Another objection is, that when you put the supers on the hives, in spring, you run the risk of exciting the bees for rob, it is very often before the opening of the crop that the supers are put on the hives. It is true, the same precaution might be taken in the spring to put the supers on the hives as is taken to return them from the fall, by doing it at the end of the day's work, just before night, so that any excitement caused by the running honey will soon be quenched by the shadows of night. But it is much more difficult to do this, because then you have a force of four or five people on the spot, than to do it in the spring, when the apiculturist is usually alone to do the work.

There is also another objection to leaving all the combs daubed with honey for four or five months—it is the danger of causing a fermentation in this honey. We all know that honey has a strong tendency to the absorption of moisture—it then becomes watery, and ferments easily. When the bees are started, and over the winter, it is very easy for them, while extracting, there is a very great danger of this fermentation, and though the quantity is very insignificant, it produces numerous germs on the combs which are to contain the crop, and it is difficult to remove them in the spring.

It is true that it takes a little more labor to put the supers back on the hive, when we know that they must be again taken off before winter, but it is thus with every pursuit—we can have nothing without labor, and those who take the most pains are usually those who succeed best.

Hamilton Co., Ill.

Long-Tongued Bees—A General Rejoinder.
BY G. M. DOOLITTLE.

MY article on long-tongued bees, on page 293, seems to have stirred them up quite generally, if what has appeared in print on this subject since that time gives a true representation of the matter. And I have waited a little, till "the storm had passed away," so that I might send in a general reply to all, for I see that I did not make myself fully understood in my former article. Some seem to get the impression that I was accusing advertisers of making "false statements" regarding long-tongued bees, for the sake of gain. I did not intend so to do. What I did intend was this:

Gleanings in Bee-Culture, through "Stenog.," said, "The movement for longer tongues is simply to get the red clover crop of the North, which now is practically all wasted. The bees, no one claims, would be any better except on that account;" while in the same number of Gleanings the advertisement was stating that long-tongued bees were better for all parts of the country, red clover or no red clover, or at least with no qualifications regarding the red clover matter. And as these statements were directly opposite, I wished to show that one or the other was, and must of necessity be, "actually false." If this showing or conclusion was wrong, or if I wrote in a manner tending to convey any other impression, I am sorry, and ask pardon. I certainly had no desire to do any.

Next, to offer prizes, and so put things by editors or otherwise, as to draw out only one side, without putting the other side on an equal footing, is what I call misleading, and especially so where this is done in the reading columns of a paper in a way tending to point toward some financial interest of the promoter. If so calling was wrong, or if I wrote in a manner giving a different impression, I regret it more than any one else. Not till the "fad" for long tongues had nearly run its course, then I desired for tongues to measure from colonies which had proved themselves inferior for honey-gathering. To have been fair this should have been done at the outset.

Next, when a person writes from an opposing side, and a foot-note is used so as to turn what the opponent says that it may point toward the fad—this is what I call twisting, and something our bee-papers of to-day should not stoop to doing it. If I am wrong, I am sorry. I do not wish to look at things through a distorting vision.

Again, in closing my article I said, "There are times when it is necessary that a 'halt should be called' by some one, and as no one had seen fit to do this, I felt it my duty." Replying to this, Mr. R. Root point me to a certain editorial on pages 295-296 of April 1st Gleanings, to show that a halt was there called, which I had made no mention of, and if I would be fair I would have noticed it. Well, if I had considered that this editorial a calling of a halt I should have noticed it. Allow me to quote from it, similarly to the way Dr. Miller and Mr. Root did:
AMERICAN BEE JOURNAL

No. 10. Practical Lessons for Beginners in Bee-Culture.

BY J. B. GEHRING.

O drone-brood was found on any but the third and the fourth frames in a hive. I will not speak of any brood on none of the frames between these two, nor on the frames on the outside of the brood-nest, I reminded him of what I had previously told him about giving a new swarm a few frames without full sheets of foundation, for reasons also stated.

"This frame to which you direct my special attention," I explained, "serves, better than any other in the hive could, as an illustration of the way my theory works, as applied to the drone-comb."

"You see, here," I continued, as I took the frame in my hand, "how bees will sometimes take advantage of opportunities in their efforts to outwit the intermeddler, and to carry out their intuitive perception of the fitness of things in their household management. Had I given them a frame containing a full sheet of comb foundation, in place of this with a starter only two inches in width, they couldn't have made any drone-comb in it. They can not convert comb foundation into drone-comb—at any rate they have never been known to do so.

"Well, here is the explanation, Mr. Bond: When I hived that swarm I put only these two frames having starters in them into the hive—near the center. Four of the other frames had foundation, and were not freshly finished comb—not a drone-cell in any of these—taken from another hive, all nearly solid with ripe brood. So, you see, this colony had no chance to build drone-comb on any of the frames except these two; and here they had to make up for it by using nearly the whole space of the frames, below the starters, for that purpose."

"But I don't understand," remarked Mr. Bond, quizzi- cally, "why you allowed them to rear drones on these two frames when you could have prevented it, just as well as not. Didn't you say that you didn't want any drones here?"

"Perhaps I did say that," I replied, "and I confess that the whole matter has a queer look—must have to be seen. But the contradictions all disappear when I say: I forgot about those two frames, otherwise I would have exchanged them for drone-proof frames before the bees had time to build the drone-comb. It is true that I don't want these drones; neither do I want any more to hatch out in my apiary this summer. There are plenty on hand now to answer the only practical purpose that a sensible bee-keeper rears drones for."

"Let me tell you, Mr. Bond, the regulating or controlling of the drone-business in an apiary of even 20 or 30 colonies is, in my belief, the most difficult task a bee-keeper can put upon his business program. It demands eternal vigilance to make this effort successful, in the teeth of nature, against nature, and therefore against many obstacles; some of them unknown until learned by experience, and nearly all of them hard to overcome.

"One of the most serious of the obstacles has just been pointed out by intimation when I said I forgot about these two frames. If every bee-keeper who tries to climb to the top of the business had a good, reliable memory, instead of a first-class forgettery, that alone would go half way, at least, toward success in the matter of regulating the production of drones by the bees."

"But I don't understand," remarked Mr. Bond, "why you should go to so much trouble to prevent drone-increase if, as you say, all harm drones do is, that they eat honey and don't work.""

"Mr. Bond," I replied, impressively, "it is honey I keep bees for. As far as drones are a help to me in getting the largest possible yield each year, I tolerate them, and don't interfere with them unless it harms me, or anyone else. But when I know that my bees are rearing more drones than are needed for the only legitimate purpose, I am disposed to interfere, because I know that the honey bees are just as helpless as the drones, though the drones in a hive that are not really needed are a nuisance, because they are in the way of the workers during busy times."

"In the meantime, I'm not to say that I am not opposed to long-tongued bees, long-winged bees, or bees having large honey-sacs, etc., but I am opposed to the pushing of any of these in a sort of one-sided way, without at the same time trying to draw out the truth in the matter by giving the contrary side an equal chance. His time enough to push things after they are known to be right, and, to my mind, a thing should never be pushed by the editor or publisher of a paper until it is so known."
Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail—Editor.)

Advice to Beginners.

If you want to be in the front rank as a bee-keeper, you will do well to inform yourself upon all phases of bee-keeping. Some of you make the mistake of thinking, "Oh, that subject, or the other subject connected with bee-keeping, may be well enough for those particularly interested in that direction, but it doesn't come in my line, and I'll not waste reading it." And so you miss reading some of the very things you most need.

"How do I know you don't read everything?" I'll tell you how I know. Nearly every week—well, say once in two weeks—I get a question from some one when that question was answered not two months before. This summer the question that has come oftener than any other is the one referring to swarms absconding after being hived; and many has been the swarmer lost because the loser didn't think he needed to know anything about absconding swarms until he had one of his own abscond.

Now, I don't want to choke you off from asking questions in the least; some of you don't do as much of it as you ought; but I want to suggest that you would be the gainers if you would read up in advance what is written for others.

Not so very long ago I was told, "I suppose you don't read a large portion of what you find in the American Bee Journal." That supposition could not have been wider of the mark. Except what was written by myself, I dare not omit the reading of any word. The short letter from some beginner may say, "I can't afford to pay for the trouble of reading it, and then again one time out of a hundred it may; and I don't know which one out of the hundred may give some hint of value; so the only safe plan is to read the whole hundred." C. C. MILLER.

Swarms Absconding from the Hives.

Can you give any information about bees leaving the hive after hiving them? I have lost about half the swarms this year in that way.

WISCONSIN.

ANSWER.—The absconding of swarms this year seems to be unusual. Doubtless it is on account of the unusual heat. Do all you can to keep your swarmer cool by shading and plenty of ventilation. Raise the hive cover, and for a few days let the hive-cover be partly off.

Painting Barrels for Holding Honey.

Will it do any good to paint alcohol barrels that I intend to use for holding extracted honey?

MINNESOTA.

ANSWER.—I don't know. I doubt if it will pay, and will be glad to be corrected if I am wrong.

She Has Troubles of Her Own.

I winter my bees in a shed, long and narrow with a door in the west end. I pack them in as warm as possible, and open the door on pleasant days. Last winter I put in 10 colonies, part Italians and part blacks. I gave the Italians the warmest places, and near the door where it was almost to the cold I placed a strong black colony. Last spring, on taking them out, the colonies near the door were just overcrowling with bees, both blacks and Italians, while some of the other colonies seemed to have scarcely enough. I kept this up for the winter. One, especially, had a queen and a mere handful of bees. As soon as the weather was favorable I divided the large colony, intending to give the queeness half to the small Italian

The Premiums offered this week are well worth working for. Look at them.
colony, but before I could do it the Italians were all dead. I immediately sent South and got two queens, thinking that, as I had the colony divided, and there were such a lot of bees, it would be a good time to Italianize them. I successfully introduced both queens, but those two colonies have just deserted their hives and do not seem able to hatch out and I would find them crawling around outside of the hives. One queen turned up missing. The other deserted her hive with a handful of bees. Now, where did I make a mistake? and will those combs do to give to the other colonies? Do bees make a practice of going into different hives in winter?

ILLINOIS.

ANSWER.—To be entirely candid, I don’t know enough to say just what mistake you made, or whether indeed you made any. Possibly a fuller knowledge of particulars might help in the diagnosis; possibly not. It is quite likely that the season had something to do with it, especially if you operated somewhat early, for the spring was unusually bad. It happens only too frequently that bees desert their hive and enter another, especially in a bad spring when there is more or less spring dwindling. It will be all right to give the combs to other colonies.

Swarming—Wintering Bees.

1. I started last spring with three colonies of bees, one of which has sent off two nice swarms, another cast one, and the bees issued from the third hive, and returned to the hive without clustering. In how many days thereafter may I expect these swarms to issue again?

2. I have a room in the southeast corner of my house, with one window on the east side, and a door opening into a small, warm hall. Would it make a suitable place in which to winter my bees? If so, ought the window to be darkened, screened in or blinded, and the door closed at the door, as it does not fit very tight? There is no way of warming the room, except by opening the door into the hall, but nothing ever freezes in it unless in the very coldest weather.

New York.

ANSWERS.—1. Hard to tell. It depends altogether on conditions. If the old queen was in the hive, they may come out the next day or so, or they may not issue again till a young queen is matured eight or ten days later. It is possible that the old queen was gone, and the swarm issued with a young queen, returning because the young queen could not fly, or for some other reason, in which case they may come out any time within two or more days, when another young queen is matured. It is also possible that a young queen was present and that the swarm was merely something like an escort for the young queen when she look benefitting-trip, and no further swarming will take place. So the full answer is that there may be no further issue, and that there may be one on any of the following sixteen days.

Building Up Colonies for Winter—Buying Bees.

1. I have an apiary of six colonies. I purchased three large swarms two weeks ago, for $3.00, and hived them in Hubbard hives, and I think they have stored 50 pounds of honey each. I have three others that are not doing so well; they are weak in numbers. How can I build them up for winter? I take the American Bee Journal and think it is a great help; I also have Prof. Cook’s “Bee-Keepers’ Guide.” I am very new in the business, and need all the help I can get.

2. I can purchase colonies of black bees at $1.00 each, or can purchase this year’s swarms in good, standard hives at $3.00 each. Which would be better to purchase, the early swarms at $3.00, or wait till next season and get them at $1.00? I want to go into the business heavy next season.

Virginia.

ANSWERS.—So many things are to be taken into account, that it would almost take a book to tell all the different things it is possible might be done in order that your weak colonies have the very best chance to build up strong for winter. As the most valuable piece of advice in the case, I should say the very first thing is to study carefully your text-book. Then you will be competent to judge what is the best thing to do much better than one who has no opportunity to see the bees. It is quite possible that nothing need be done but to let the bees alone; and that they will of themselves build up strong for winter. See that each has a good laying queen. If you find four to six of the brood-combs mostly filled with worker-comb, it is likely no interference is needed. If you find everything not all right in this respect, it may be that something is wrong with the queen, and that she should be replaced.

The common good combs will tell you that you rightly, you can get colonies in hives now for $3.00, and next year you can get the swarms when they issue, without any hives, for $1.00 each. It is hard to tell which would be best. Possibly a compromise might be good here, and I hope you will number out, and fill out the quota with next year’s swarms.

Pays to Get Fresh Blood—Bee Veils and Gloves.

1. I have a few swarms of bees, the most of which I gave Italian queens, which I purchased from an Iowa breeder last year. They have hived, but I understand you rightly, you can get colonies in hives now for $3.00, and next year you can get the swarms when they issue, without any hives, for $1.00 each. It is hard to tell which would be best. Possibly a compromise might be good here, and I hope you will number out, and fill out the quota with next year’s swarms.

2. I have a veil I made myself that I like the best of any I have seen. I first take a straw hat with medium rim, then I get a piece of common window-screen about eight inches wide and long enough to go around the rim of the hat, and sew the ends together; then sew a piece of cloth over the top a little loose, so the crown of the hat will set up in the cloth; then sew a piece of mosquito net or cheesecloth to the bottom, so that the bees can’t get into the hat, and cut it on and button the coat or vest over the bottom, and it is bee-proof, and will not blow against the face nor tear easily. I find I can see better through it than almost anything else. For gloves I will use my own gloves, and other gloves, and other gloves, and other gloves, and other gloves. Some very long wraps made of thick cloth that will come nearly to the elbows. With this and my bicycle guards on my pants’ legs, I can handle bees with as little fear as if they were chickens.

MINNESOTA.

ANSWERS.—1. Other things being equal, there will be some advantage in getting in fresh blood.

2. If you make much use of a veil you may injure your eyesight by looking through wire-cloth. If I remember correctly, one of the veterans had a very bad time with his eyes ago in that very way. It is better to have a veil that does not require either coat or vest, for bee-keeping is too hot work a good part of the time to wear either.

Biographical.

MR. FRIEDMANN GREINER.

On the first page of this number appears the portrait of Friedmann Greiner, one of the American Bee Journal’s best contributors. His love for insects and insect life manifested itself early in his younger days. As a boy of six or seven he well remembers spending hours and hours at the old bee-kills, his grandfather’s private bee-kills and how he would comb the frames, and later on, the bees, and get them out of the straw-skeps; and what pleasure it afforded him! The school-lessons, and he regrets to say hours, were clean forgotten many a time. Too often did he have to hear the older brothers and sisters and cousins fair hunting for the honey and the bees, and the old bee-kills had been neglected: “Well, Greiner had to take his grandfather’s bees out to pasture; couldn’t attend to his study.”

Mr. Greiner was not all concentrated in bees, but other insects shared likewise. His collections of butterflies, beetles and other animals are the envy of his schoolmates. Many days did he spend in the search of rare caterpillars, which, when captured, were fed daily with such food—leaves, plants, etc.—as comprised their accustomed food. When finally the caterpillar had gotten its growth, spun its cocoon, it was with much anxiety that the forthcoming of the butterfly or moth was awaited. When this happy moment did come, the specimen was treated to ether, thus killed, and then prepared for the collection. He always knew where to find rare specimens of water-beetles, etc.

When his grandfather died, the bees went into other hands, and for years not much thought was given them.
But soon after he arrived on the shores of America, at the age of 20 years, his interest in the little busy worker was rekindled, and developed into a disease known otherwise as "bee-sickness." 

With great enthusiasm he took up the bee-business as his life occupation. Not being sufficiently conversant with the English language, the German bee-literature was studied by him who used it to think as he never thought before, and who never understood the bees. 

He finally decided to stay in New York, where he owns a small farm devoted principally to fruit-growing.

Mr. Greiner's anticipations to become rich through bee-keeping did not materialize, but, loving them, he sticks to them, always having some experiment going, sometimes on a wild-goose chase, sometimes after realities, but the pleasures he secures, he says, are many times greater than the profits.

**The Afterthought.**

The "Old Reliable" seen through New and Unreliable Glasses.

By E. B. HASTY, Sta. B Rural, Toledo, O.

**BEE-KEEPERS' EXCHANGES.**

Sometimes an argument is a sword which cuts both ways whenever it cuts only one way. Mr. C. A. Hatch, in arguing for exchanges, says: "It is only when the soldier ceases to be an individual that the army becomes a power. That sounds conclusive—perhaps is conclusive—but those of us who value our individuality too much to give it up may, as a little thing: The British soldier is more than an individual than the Russian soldier; the American soldier is more an individual than the British soldier; and the Boer soldier is more an individual than the American. We do not consider the mere succession a diminuendo, but the opposite. And is it not true that the individuality of the Boer is the very thing that makes him terrible? Now if the Russian and German armies overdo the business of taking away individual initiative, may it not happen that our bee-keepers' exchange will do the same thing?

**REPUTATION AS A HUMORIST.**

I shall get a reputation as a humorist if the proof-reader keeps on helping me. On page 473, in the place of "500 years" during which the family was to abstain from honey read—something else—probably simply for years. Also inserted of punctured with dead flies read punctuated with dead flies.

**SWEET CLOVER.**

The Wisconsin Farmers' reply about sweet clover, on page 397, seems to me to be, in the main, a calm and reasonable article. Believing it did not detail the good points as much as the bad, I have done. I fear that rejoinders like Mr. A. H. Hatch's were too well calculated to make the great big outside world of mankind think that we are a small group of cranks—cranks incapable of recognizing beans, when the literature of the bag has been done loosened before our eyes. Many years ago I introduced sweet clover into our garden. For most of the time it did practically no harm—that is to say, made me little if any more work than the other plants would, which, in the absence of the sweet clover, would have been claiming the same space. Quite recently it has made itself a big nuisance in the ground occupied by asparagus and winter onions and strawberries. Too tough to hoe out, or chisel out, too strong to pull, and with multiplying powers like the potato bug's. This power gradually to fit itself into new situations is a dangerous one. In my early enthusiasm for sweet clover I sowed some by the roadside (not beyond my father's estate, however) and to the best of my knowledge not one plant from that sowing ever came to bloom. But after a dozen years it began itself to travel out from the garden along the road, and is now abundant for quite a distance.

Dr. Miller and His 70 Years.

And so our beloved Dr. Miller, senior member of the staff, is seventy years old. The burden of declining years is but poorly got rid of by pretty speeches, but we will hope that the labor and Moscow War speak so pathetically much more light on his case than that Power which overshadows and holds all our lives. It turned out so in Moses' own case. Moses probably wrote that Psalm when he was only seven years old, expecting the next ten years to be spent in the desert, with death somewhere near. It turned out that he didn't begin to live on a grand scale until he was eighty, and that he finally died at a hundred and twenty without his eyes being dim. Courage and cheer, O conrade! When on earth shall we be open, and the servants of God ascend and descend upon the Son of Man, you and I shall come from one of the planets of Alpha Centauri, where we have been telling good news (and introducing bees?), and our eyes shall not be dim, and our hands shall not tremble. Pages 401 and 402.

**BREEDING BEES.**

It looks possible, dear "boss," that a cross between poor-looking hybrids and five-banders might result in three-banded bees—to the confusion of the purity rule. Let's not be too sure of it, however, or we might have seen it. From what we know of crossing, and its relations to sporting, we would be much more likely to get a colony of all stripes and colors from five bands to none—no evenness in anything. Page 403.

**HOW TO "SPOT" DRONE-COMBS.**

Red spot painted on the bar right over a patch of drone-comb. Thanks, Mr. Doolittle. Those who wish to do the utmost in the line of controlling drones will do well to take heed. Page 403.

**The Home Circle.**

Conducted by Prof. A. J. Cook, Claremont, Calif.

**RECREATION.**

If the various home circles could now (July 17), look in upon me and mine at this delightful vacation time, no one would wonder at my theme which I bring into the homes to-day. Where are you? Away up in the mountains. If we could only recognize, let us from time to time, that we read daily of the terrible heat in all the Eastern cities, I am writing this early morning with my heavy winter overcoat about me, and half wishing it were warmer. While our friends in California are moving around as the rain comes not, our tent is pitched close by a rapid mountain stream, whose waters, fed by the snows hard by, are as cold as they are pure and refreshing. As we lie in our beds, the rippling waters, as they dance over the rocks, sing to us all the night long. This glorious scene soothes our inflammable souls. Here we have fixed our vacation sojourn, so that they hem us in, and we are really on an island. The little valley in which our rest-days are flying so rapidly by, that we sigh that the end will come so soon, are so heavily wooded that both shade and seclusion are ever awaiting those who wish to enjoy them. The great mountains, which shut us in on all sides, are also heavily wooded, and we rejoice constantly in the soft, green landscapes which holds us in its embrace. Northwest of us is "Old Baldy," which reaches nearly 11,000 feet skyward. Its snowy summit is only sixteen miles away, and tomorrow our party of eighteen are to scale its heights. It is a cool, delightful, restful place. I think I have before mentioned our Southern California blessings in these home papers. The marvelous scenery everywhere; high mountains, grand as beautiful; lovely valleys verdant with alfalfa fields, and ripe-leafed with beautifully kept orchards; delightful fields, with no sunstroke, but which hands forth warmth and sunshine every week the year through; delicious water that comes pure and sparkling right from the mountain rocks. If typhoid germs use it, it is not so clear that we fail to look bright on our Southern California homes, it will speak of gross neglect or carelessness in the homes that are shadowed; most luscious fruits, our party right from our own orchards and gardens bring for our refreshing—strawberries, lemons, pomelos, plums, apricots, apples, peaches, and I might have added strawberries, blackberries, raspberries and nectarines. And all these
so sweet and delicious that they nearly melt in the mouth: and, as I usually say, best of all, a grand, true, splendid citizen-ship. Doubtless God might have made a better people than sojourners in our beloved sun-kissed California, but doubtless God never did.

This usually completes my summary, but I desire to add another. Almost all our Southern California homes are so close by sea and mountain that either are within a day's journey by horse, or a few hours by cars. Thus, if heat does come, we can flee its presence, and bathe in the clear, pure delightful mountain air, or the warm, refreshing water of the ever restless Pacific. This is no mean advantage. How many hundreds of homes and hearts have been recently seduced in the East, as drought, hurried on by the crushing heat, has snatched the loved ones, forever away. Here such crises never come to menace, for at the seashore, or in the mountains, we are safe—always safe—from their evil work. I hardly know which I enjoy most, the wondrous air of the mountains, or the hushing breeze and bracing waters of the ocean. When here, I think the mountains hold forth superior charm; when there, the sea seems to offer most that enamors, and invigorates. Either is delightful, and we rejoice with fervent thanksgiving that we can taste so easily and often of both.

Do we in all our home circles think enough of recreation? We are a very earnest people. So intense are we in our business that I fear we often lose sight of the good that may come from the picnic, the camping out, the mountain sojourn, or the weeks by the seashore. We are so fashioned, that the wheels of our human machinery run more smoothly, and will of a surety run longer, if we tend them ever and anon in different grooves. Just as the stomach wakes to greater strength and added energy when given a variety to work upon, so the whole body craves new scenery, new activities, a halt in the everyday round, and a push into work or play that recreates, because new and fresh.

Let us all, in every home circle, plan as best we may to find time to break from the usual routine of work and duty, and in some forest, or by some lakeside, alone, or better, with other families, seek out a different life, and thus make the young younger, and carry youth into old age. And more than this, we will find that we will come back to the usual duties with so much of added strength and vigor that oftentimes we shall soon more than make up for the days of absence, as we will easily do more and better work.

In planning our outing, let us not only arrange for pleasant friends, and wholesome fellowship, but plan for games, music, and reading. Last night we met with many other campers, and had a splendid concert. A piano had in some way reached this retreat, and we did sing with genuine spirit. I heard more than one say as we said our adieux, "It has been the pleasantest time since we came." For the children, Captain Jack, and all the work and no play, and endeavor to make the too just criticism of our English friends—that we think too little of rest, recreation and a good time—less true.

**THOUGHTFULNESS.**

There are few things that will reveal character like a few weeks' camping. We soon find that some of our party are so thoughtful, so helpful, that we could not have spared them. They are always just where needed; they are ever planning, and successfully, to make all more happy. They are so handy in fashioning the conveniences about the camp, so fertile in preparing meals, so handy in keeping all neat and tidy, that they really are like "a thing of beauty." Were I a young man or woman, and in pursuit of information regarding the character and temperament of some special person of the opposite sex, I should arrange to be for a month in a camping party with them.

**"The Hum of the Bees" in the Apple-Tree Bloom** is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at $1.00.

Please send us Names of Bee-keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

**Our Wood Binder** (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of $1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it.

ADVERTISEMENT.

To Our Shippers:

We were obliged to notify you a few weeks ago that one Joseph M. McCaul had leased our old quarters at Nos. 120-122 West Broadway, New York City, and had there started up business under the name "Hildreth, McCaul Co.," and had distributed a multitude of circulars so worded as to create the impression that his business was a successor to or a branch of the business of Hildreth & Segelken.

For the protection of our shippers and ourselves, we at once instructed our attorney to commence action to enjoin the said McCaul from using the name HILDRETH in any manner whatsoever in connection with his business. On the 10th day of July, 1901, Hon. David McAdam, Justice of the Supreme Court of the State of New York, after a full argument upon the merits, issued a peremptory injunction, of which the following is an extract:

"And it appearing that the plaintiffs have for a long time been and now are carrying on business under the style of 'Hildreth & Segelken,' and that the defendant has recently opened a business at 120-122 West Broadway, in the Borough of Manhattan, City of New York, and is carrying on the same under the style of 'Hildreth, McCaul Co.,' and that such act is in violation of the plaintiffs' rights, and that the commission or continuance thereof, during the pendency of this action will produce irreparable injury to the plaintiffs; it is

ORDERED that the defendant (Joseph M. McCaul) and each of his agents, servants and employees and all other persons acting under his authority and direction be, and he and they are hereby restrained and enjoined from showing, displaying or otherwise using during the pendency of this action in or upon any papers, devices, sign or signs, or otherwise, in the business conducted by the defendant at No. 120-122 West Broadway, in the Borough of Manhattan, City of New York, or elsewhere the name of "Hildreth" separately or conjunctively with any other name, designation or description."

Outside of our desire in our own interests to protect the name which we have built by years of satisfactory dealings with our customers, we hastened to procure this injunction as soon as possible, to prevent our shippers from being misled into sending their goods to one who would make an attempt to gain their trade by such a trick and device.

With thanks for the many expressions of good-will we have received from our shippers concerning this attempt to trade under our name, we are,

Sincerely yours,

HILDRETH & SEGELKEN,
265-267 Greenwich Street, NEW YORK, N. Y.
DO YOU WANT A HIGH GRADE OF
Italian Bees and Queens?

2-frame Nucleus with Untested Queen, $2.00, purchaser paying express charges.

Naperville, Ill., May 28, 1911.

DEAR SIR:—Bees and queens in good condition. Transferred them to hive and gave them honey, which they are doing. Are working when not too cold. Have right color, and are satisfactory.

E. B. GIVENS.

I like your way of packing bees to express.

E. K. MEREDITH, Batavia, Ill.

Dear Sir:—I have 1000 sections from this flow, and at this date about one-half has been sold right at home.

B. R. MCDANIEL.

Tt

Best Honey-Year—Swarming.

This is the best honey-year we have bad in northern New York for three years. There is lots of white clover and basswood. It has been necessary to go out and stop swarms several times. When I returned them, the second night, they would come out again, so I lift up the back part of the hive and run them in that way, and they almost always stay. I have not had a swarm come out when put back in that way.

R. V. Goss.

A Fine Honey-Flow.

My bees were just able to make a living up to June 28; since then we have had a fine honey- year, with raspberries and saucin. I will have 1000 sections from this flow, and at this date about one-half has been sold right at home.

B. R. MCDANIEL.

Athens Co., Ohio, July 22.

Bees Carrying Eggs Down.

Is this anything new? Two weeks ago I noticed a colony of my bees, which had swarmed in the spring, had failed to provide themselves a queen, so, as they had a super on, I experimented by catching a comb of brood from a square inch containing eggs from another colony, and grafting it in one of the sections in the hive. The bees never seemed to care. The following day I looked at the job, and the eggs were gone. To-day I looked among the brood-floors and found not a single egg of brood about an inch square, and a queen-cell nearly ready to hatch. Clear ease of carrying brood (or eggs) down, isn’t it?

R. V. Goss.

Very Dry in Indian Territory.

The bees here in Cherokee Nation are doing nothing on account of dry weather. Out of ten colonies in spring, I only got one swarm. The bees loaf and cover the hives. I have raised the hives an inch from the bottom-board. If cotton-bloom has any honey there ought to be great quantities of surplus, as no swarming has made them very strong. So far this season we have had little rain and nothing to gather. If the cotton proves a failure, not half the bees will have enough to winter on.

The hives are in their natural condition. The fruit barns or takes on the trees; corn and grass look as if a heavy frost had struck them. We have had three periods of rain, and none since, like in October. The oldest people living never knew the rivers and streams so low, and many of the rivers dry up, and then burning great bonfires and burning the grass and big drifts on the rivers, for rain. All over the Indian country there is almost a total failure of crops, and unless it rains in a very short time corn and grass will burn up.

C. B. SLAUGHTER.

Cherokee Nation, Ind., Ter., July 13.

A Report from Arizona.

On page 435 we read what Editor Root says about the heat of Arizona, which probably is true, but we have found in our experience that there is still 50 degrees difference in the effect of the heat between a damp and a dry atmosphere. All our figures are the result of our observation of the weather conditions in various parts of the country and northern States, if you wrap a thermometer with a damp cloth it will show the same temperature, but if you drop 50 degrees. I am now making butter by keeping the milk in a cupboard out, with a tank full of water in the next room and wire a fan to run on all sides; the air passing through the damp cloth lowers the temperature.

I have been running the extractor con-
Harvest Rich, But Short.

The honey harvest has been rich, but rather short. At the beginning of the wildflower bloom the weather was cool and wet, and the flowers did not yield much nectar, but after a while it turned warm, and the bees made up for lost time. With the yield of honey the bees commenced to swarm. I have not had many which swarmed a long time, but have several large colonies, where two prime swarms went together. I put two of them on scales, and kept a record for several days. One was hived June 18 on empty combs in a 10-frame Langstroth hive, with two upper stories filled with nine combs each. The morning of June 19 they weighed 91 pounds; June 20, 86, the day being cloudy and showery; June 27, 92, and were 91 pounds; June 22, 12%, pounds; June 23, 15% pounds.

The other was hived on empty frames with two surplus cases of 32-pound sections each, filled with comb foundation; weight on the morning of June 22, 111 pounds; was not 28 colonies to start with, but there was enough honey in the fields for 200 colonies to have done equally well. Last year I had 15 colonies, and it was all they could do to produce a half of the amount we get now. Since the close of the white clover harvest the bees have been working some on red clover, but not the long legged, but also the short-tangle, the banded and striped, hybrids, and other bees. In fact, bees will work on any sweet, red clover in this part of the country for a few days in the year, if they have the right kind of weather.

Ref. Editor, If we stretch the bees tongues is there, no danger that we may shorten their stings. I have a swarm of extremely hot and dry bees present, the thermometer ranging here from 100 to 108 degrees in the shade. My bees are exposed to all the rays of the sun; there are no buildings or trees near them. If the weather is dry and the swarm weather they usually hang out, but this is too much for them, and during the heat of the day they will go into the hive to cool; the bees come out again as the day draws to a close. How they keep the combs from melting down is more than I can understand, for honey is packed white, are set on posts about 4 inches high, and the grass and weeds are kept down with a lawn-mower. The flowers of my hives are the old style 7½-inch, telescoped caps, resting on elets like the Dahlart hive.

We will mail one of the above queens alone for 75 cents or 3 for $2.00.

Please do not conflict the above offer

We will mail you one of the above queens for $1.00, and

25 cents, we will mail you free an Untested Red Clover Italian Queen. For sending us one new subscriber at $1.00, and

25 cents, we will mail you free an Untested Red Clover Italian Queen.

A HANDY TOOL-HOLDER!
Sent by Express, for $1.50; or with the Bee Journal one year—both for $2.00.

Every Manufacturer, Miller, Carpenter, Cabinet Maker, Machinist, Wheelwright and Quarrystone Farmer, or any one using a grind-stone, should have one of these Tool-Holders.

One boy can do the work of two persons, and grind much faster, easier, and with perfect accuracy. Will hold any kind of tool, from the smallest chisel to a draw shave or ax. Extra attachment for sharpening seylo blades included in the above price. The work is done without wetting the hands or soiling the clothes, as the water flows from the operator. It can be attached to any grind stone, or place of power, is always ready for use, nothing to get out of order, and is absolutely worth 100 times its cost.

No farm is well-equipped unless it has a Tool-Holder. Pays for itself in a short time. 

How to Use the Holder.

DIRECTIONS.—The Tool is fastened securely in the Holder by a screw, which can be ground to any desired level by inserting the arm of the Holder into a higher or lower notch of the standard. While turning the crank with the right hand, the left hand on a steady the Holder; the Tool is moved to the right or left across the stone, or examined while grinding, as readily and in the same way as if held in the hands.

For grinding Round - Edge Tools, the holes in the standard are used instead of the sockets.

Why not get out a few of these splints, and give it a trial? We are convinced that they will meet with your approval.

Artificial Swarms.
The editor of the Rocky Mountain Bee Journal says:
The method we use and prefer is to place a new hive filled with foundation starters on the old stand; shake off about seven-eighths of the bees, including the queen; put on a super of sections filled with full sheets of foundation. If honey combs are put in the super, they will at once enter the super and work there clear through to the end of the flow. A queen-excluder should be put between the super and the brood-chamber. The old hive containing the brood and remaining bees should be placed in a new stand and given a nucelle or laying queen. By this plan we get a hiving colony composed of all the field-bees and a large force of nurse-bees and comb-builders. If the division is made at the beginning of the flow, the old colony will hatch out bees to be supplied to bees in the hive in time to keep the hives crowded with bees in order to secure a good yield of section honey.

"You are not the first one to ask such a question, Mr. Brown, for this is something bee-keepers have been doing during the past quarter of a century. If the aphislas has done what he could to get his hives full of brood at the proper time, then it is likely that bees available in time for the honey harvest—hives over-flowing with bees, as you say yours are now—and are in condition to be swarmed, the bees should be done before the height of the season arrives."

"But I suppose you did not allow your bees to swarm, for I am told, no large amount of section honey can be obtained if we let our bees swarm."

"In this you err, for the swarm and parent colony, if rightly managed, will do fully as much with the average bee-keeper, when only one is allowed, as could not have been done were not allowed to swarm; and, besides, if we tried to keep them together by cutting out queen-cells, the swarms are probably in the room, etc., we would, as a rule, only delay swarming; so it would come during the last half of the honey harvest, when it would be the most detrimental to our interests."
section-boxes being put from one of the old colonies containing the alter-swarms. Then this old colony is put on a new stand, and the hive containing the two swarms. The bees, thus given the field-keeps from this colony, in addition to the two swarms, which makes a colony which will have been brought out of its normal harvest, a colony from which I take 100, 150, and even 200 one-pound sections of the choice of honey, according as the season will prove.

" But what about the queens? Do you let both swarms make new queens?" "No. The queens, having their wings clipped, give me the power of disposing of them as I think best, and so I let the queen go back with both swarms. I put on a new stand, and allow the one from the colony not moved to go with the united swarms. But this is not an old colony, for 80 percent of the bee-hive, but also all of its field-keeps, so that poor that the queen-cells are torn down, and we get the field-keeps of this colony soon picks up from the multitudinous emerging brood, so that it often will go on after the queen is killed.

"But will there not be alter-swarms from the other parent colony?" "Yes. The tendency is that the queen for the doubting swarms is not disturbed in eight days, at which time the first young queen will have emerged, which will be, of course, should be opened and all queen-cells destroyed, which will entirely prevent any attempt at a queen from this colony."

"But if all have not swarmed up to within a day or two of the opening of the harvest, what do you do with them—keep on using two queens?"

"No. All that have not swarmed at the commencement of the honey harvest, I consider as of no account. A hive is filled with frames of empty combs, or those partially or wholly full of honey, and up to this period of the year, the combs which have not swarmed, and all the sections are taken off and placed thereon; then all the bees are smothered off and put into a room of brood and honey in front of this prepared hive. Thus we have the bees, partly filled, and make them ready for business at once. Previous to this a few nuclei should have been started, so that we may have the need into the sections in a very few days. The removed colony has simply taken the old or field bees, so as to stop the swarming."

Winter Problem in Bee-keeping—Dr. R. P. Pierce—Result of 25 years' experience. 30 cts.

HONEY AND BEESWAX

MARKET QUOTATIONS.

Chicago, July 18.—Choice white comb honey is $1.00 per lb., light amber, $1.25; dark, $1.75; with good demand. R. A. Burnett & Co.

CINCINNATI, May 17.—No demand for comb honey, also stock of it well exhausted. Extracted, 25 cents. B. H. Wetter.

BOSTON, June 29.—There is practically no comb honey available and owing to warm weather very little call for same new comb early next month. Market for extracted, at 60 cents.

BLAKE, SCOTT & LHR.

OMAHA, May 1.—Comb honey, extra white, 24-frame cases, per c., $3.00; No. 1, $3.25; amber, 250 gr. per c., $2.25.

NEW YORK, July 8.—Our market is practically bare of comb honey, and demand good for white comb. Stocky sells readily at 15c.; No. 1 white at 16c. Dark. Sold out. Extracted not in much demand, with plenty of stock on hand. White, 60c.; dark, 75c.; amber, 55c.; dark, 45c.; beeswax at 25c.

HILDEBR. & SCHR.EL.

ALABAMA, June 17.—Honey market is dry. Market for comb honey, 15c. to 20c. per lb. M. H. Hunt & Son.

BUFFALO, July 10.—No demand for honey yet unless a very small amount of fancy white at perhaps 151/2c. Some old 10c. Artf. expect salable, almost, at 6, and 10 cents. Bee~wax, 22c. & c.

BATTNER & CO.

KANSAS CITY, June 14.—Very little old honey on the market by reason of the heavy new granulated. Sales are light at 15c cents for best grades. Missouri, 10c. Bee~wax firm at 28c. & c.

W. K. CROMWELL PRODUC Co.

SAN FRANCISCO, June 14—White comb, 111 12 cents; amber, 90 15 cents; dark, 66 15 cents. Extracted, white, 5c.; dark, 10c.; amber, 40-45c.; beeswax, 35-40c. Bee~wax market shows no material improvement, but there are two large lots of catgut to be sold and prices generally named by dealers. In a small way, especially, it is desirable quantities, and higher prices than are quoted are being realized.

1901—Bee-Keepers' Supplies!

We can furnish you with The A. R. Root Co.'s goods at wholesale or retail at their prices. We can save you freight, and ship promptly. Market price paid for beeswax. Send for our latest catalog.

More Bee-Keepers' Paradies....

E. R. Root has just returned from a 6,000-mile trip through some of the best bee-locations in the world, and has already begun his series of write-ups, accompanied with fine photos, in Gleanings in Bee-Culture. The following editorial appears Aug. 1, and will give something of an idea of what he will describe:

Some little time ago I promised to tell about the bee-keepers' paradise in Texas. I have this on the docket, and it will appear as I take up the line of my travels. But since running across that paradise I have run into two or three others. There is one west of the Rockies, in Colorado, that is not yet overstocked with bees or bee-keepers; another one in Central Idaho—in fact, I do not know but the whole State. These will be described in turn. The fact is, millions of capital is being invested in irrigation; irrigation means alfalfa; alfalfa means a paradise for bees. But I found all along my trip that alfalfa-growing preceded beekeeping by two or three years, for it seems to take about that length of time before beekeepers find these gold-mines that have been hitherto unoccupied.

If you are dissatisfied with your present location, and for financial reasons, or on account of health, will be compelled to leave, subscribe for Gleanings in Bee-Culture, and learn something about the great South and the great West. There are many locations in the West that are not yet occupied—splendid bee-locations. If you wish to learn about them, send 25 cents for a six-months' trial subscription, or $1.00 for one year and one untested Italian queen. Or, send $2.00 and we will send Gleanings one year and one of our celebrated Red Clover Queens.

THE A. I. ROOT CO., Medina, Ohio.

APIARY OF H. W. CORNELISON, WASEBURY CO., WIS.
(See next page.)
Weekly Budget.

HON. EUGENE SNEOR, of Winnelago Co.,

Iowa, writes as July 25, said:

FRIEND YORK,—The past month has been unprecedentedly hot and dry. Bees leaving outside the hive to prevent combs melting.

The following lines express part of what we have endured in the last two weeks:

* * *

SOMETHING IN THE AIR:

From out the burning east Comes fiery Sol:

At God's first call He climbs the heavens to feast On wilding corn and ripened grain.

Turned yellow ere its time for lack of rain.

The rolling cattle seek The airy steep.

Or feel deep In nearest friendly creek:

The pastures, shorn and parched to brown,

In vain appeal for the rain to come down.

The hot earth shrivels and cracks Beneath the glare.

And men shun care As deer shun hunters' tracks.

And every bee to hell Is praying in animal language for rain.

Outside the hive the bees Are forced to rest

To cool the nest,

And wait for beneficial trees

And flowers to yield the diurnal drop Which heat and drought have caused to dry up.

No woodland song is heard From feathered throat—

Termed cloistered

Is dead within the bird;

He pants and seeks the spring in vain—

The fountain itself is thirsty for rain.

Thus wears the torrid day,

The round, red sun

Has course run

And no man bids him stay.

For night is welcome since within

Such days will never bring the longed-for rain.

EUGENE SNEOR.

* * *

MR. ELLIS E. MASON and Miss Anna E. Hirth, both of Toledo, Ohio, were married July 24, 1901. Mr. Mason is a son of Dr. A. B. Mason, secretary of the National Bee-keepers' Association.

May long life and much happiness be theirs.

HON. H. W. CORNELISSEN, of Washburn Co., Wis., has a very nice apiary as is shown on the first page. The picture taken from the northeast corner of the apiary looking to the southwest. The bees are located against the hills, and the ground being rough Mr. C. has elevated some of the hives in order to level up and avoid washing by heavy rains. The row of posts in the middle of the hives were used to support poultry-netting. The trees in sight are butternuts, and his bee-supply house is at the right, obscured by the trees. The hill sloping to the north affords protection from strong south and southwest winds, and a tight board-fence extends along the north side of the apiary.

Mr. Cornelissen calls it "Summit Apiary," as the town is situated on one of the highest points in the State. The lake on the shore of which the village is located is called "Summit Lake," it is about 3 by 4 miles in size.

"THE HOME CIRCLE."—A. I. Root quotes approvingly a passage written for "The Home Circle" of this journal, and says:

"There is one special point in the above that is worth noting. In any contest requiring the fullest development, both of nerves and muscles, and especially alertness as well as strength, the young man who does not use tobacco will, as a rule, come out ahead: expert cyclists learned this a long time ago; and in every department of business where a clear head and a cool, ripe judgment are required, the boy or man who lets stimulants alone has the advantage. Long live 'The Home Circle' in the American Bee Journal; and may Prof. Cook be spared for many years to conduct it."

MRS. JUDGE E. G. BRADFORD, of Newcastle Co., Del., is making quite a success of bee-keeping. A local newspaper, dated Aug. 2, says she has an apiary of 20 colonies, and that from one colony she took 140 pounds of honey recently. The other colonies were also in good condition, and promised an equally fine yield. Continued success to the "Mrs. Judge."

Mr. A. I. Root, no doubt to the delight of his old friends, perhaps forced into it by the absence of his son Ernest, has been giving considerable attention to the columns of our journal, and he has been of especial interest as a result to the subject of bee-keeping. He seems to be especially interested in the great difference in bees, and wants the experimenter stations to tell us whether 40,000 bees in one hive gather more honey than 40,000 bees in another hive. If he will cabbages and posies alone long enough to give continued attention to bees, he will probably find there is as much difference in them as in folks.

THE NATIONAL ABBEY of bee-keepers is still growing in membership. Since our last report we have received the following names, and one dollar each:

JOHN SCHAFMAN, JAS. PONDHEIER, H. H. MOE, E. M. BRANDENBURG, W. W. WESTOTT.

General Manager Secor, in a letter dated Aug. 1, says that the Association membership list "will crowd 1000 before September." That's good. Now, if only a lot more bee-keepers would feel sufficient interest to send in their dollars for dues, we would be glad to announce their names in this column.

We started out to get 200 members before the first of July, but found that the Association membership list "will crowd 1000 before September." That's good. Now, if only a lot more bee-keepers would feel sufficient interest to send in their dollars for dues, we would be glad to announce their names in this column.

The pictures shown herewith is a reproduction of a motto queen-button that we are furnishing to beekeepers. It has a pin on the underside to fasten it.
Shipping Comb Honey.—As the list of readers of the American Bee Journal is constantly increasing by the addition of new and inexperienced beekeepers, it seems almost necessary to mention some things at least annually. One of the "things" is that of preparing comb honey for shipment.

All comb honey should be put up (see think) either in 12 or 24 pound single-tier cases, the former showing three sections through the 3-inch glass front, and the latter showing four. After placing the sections in the cases with a follower back of the last row, and newspaper crowded in back of the follower, to act as a cushion, then put a dozen of the 12-pound cases or nine of the 24-pound, into a large crate. First, however, there should be several inches of straw put in the bottom of the crate to act as springs or cushion under the cases of honey, to insure safe handling.

It is best, also, to have say 13x1 inch boards nailed edgewise along the top of each side of the crate, and extending six or eight inches beyond the ends, to be used as handles by two men to enable them to carry it between them when loading or unloading.

Some firms send out the following directions to shippers of honey:

1. Put your name on the crate. No name on crate.
2. Put a caution card on each crate.
3. Put the gross weight, tare, and net weight on the front of glass side of each case before packing the honey in crates.
4. Put the total weight of all cases on the upper side of the crate, so this can be found without opening the crate.
5. Mark each case with the grade.
6. Mark each crate with the grade.
7. Put only one grade in a case.
8. Put only one grade in a crate, if possible.

Comb honey put up as above, should go safely anywhere with almost any kind of handling. It pays to prepare it properly, for it profits the bee-keeper nothing to produce a lot of nice comb honey and then have it broken and smashed in shipping, on account of careless or inadequate preparation for safe transportation.

The Building of Drone-Comb.—The editor of the Bee-Keeper's Review despairs thanks for calling attention to an error in these columns which should not have occurred. He says:

Drone-comb is seldom built by a newly-hived swarm for the purpose of rearing drones. As a rule, such comb is used for store-comb the first season. I mention this as I see an editorial in the American Bee Journal in which one objection urged against the use of starters in the brood-nest is that drone-comb is built, and, "as fast as it is built it will be more filled with or less drone-brood—generally more—and that brood is a waste." If frames furnished with starters are placed in the brood-nest of a colony just before it is ready to swarm, these frames will almost surely be filled with drone-comb, and the cells filled with drone-brood; but when a swarm is hived upon, starters, no drone-comb will be built so long as the queen keeps pace with the comb-builders; but let the queen get behind, or go back to fill the cells from which the bees are hatching in the center of the brood-nest, and comb is then built to store honey in, it is quite likely to be store or drone comb; but it is very seldom that it will be filled with drone-brood at the time that it is built. By sorting over the combs in the fall the drone-comb can be taken out and used after that in the sapers. Contrary to the belief of some, I believe that, under such conditions, combs are built at a profit even if they are to be melted into wax.

Mr. Hutchinson is quite right in saying that drone-comb when built by a swarm will not at once be filled with brood. The question, aside from that, whether it is advisable to allow such comb to be built, afterward to be cut out by the bee-keeper, is an open one. For one who has plenty of time for the work, and who will do it, the plan may be all right. It should be understood that it is possible to have all combs worker-combs without the use of founders. In some cases this may be said, but in exceptional cases where labor and time are in so much greater supply than money to buy foundation that it may be economy to dispense with the latter. Given a lot of combs containing patches of drone-comb of greater or less size, it is certainly paying work to cut out all the drone-comb and replace it with patches of worker-comb. It is well, however, even for one who thinks it advisable to dispense with foundation to take some pains to limit the amount of drone-comb built. It is usually practicable to do this by taking advantage of the fact that Mr. Hutchinson mentions, that soon as the laying of the queen in a swarm keeps pace with the building of comb there will be no drone-comb. Hive a swarm on four or five frames, and little or no drone-comb will be built until these are filled. Then foundation or drawn combs may be given to fill the hive, or, if only starters, the drone-comb will be limited to these latter combs.

It is well to know, also, that nuclei or weak colonies may be depended upon almost entirely to fill in holes with worker-comb, whereas if a patch of drone-comb is cut out of a broadcomb, and the comb returned to a full colony, the hole will be most likely to be filled again with drone-comb. The age of the queen makes a difference, the older the queen the greater the inclination to build drone-comb, even a very weak colony with an old queen sometimes insisting on building drone-comb.

But when all the trouble and inconvenience of mending combs are taken into account, the number is very large to those who think it cheaper in the long run to forestall the actions of the bees by filling the frames with worker foundation.

Utilizing Cappings.—Efforts have been made at different times to get bees to use wax in building combs, the wax being furnished by the bee-keeper. Success has not always attended the efforts. E. Puffy now reports in the French journal, Revue Internationale, that he has had excellent success. He gives back cappings to the bees. The secret of getting the bees to use them lies in the technique between the layers of the cappings. It is essential that the cappings be not washed. Taken just as they come from the uncapping knife, they are packed into a ball from the size of a walnut to the size of one's head, and put in the hive beside the feeder. Combs are then built out rapidly.

The Honey Crop of 1901.—Editor Root has been scanning the field, and concludes that beekeepers need be in haste to dispose of their crop for fear of glut. Even if the season were better than last year, there were fewer bees to gather it this year, especially in Southern California, where probably three-fourths of the bees have died through neglect or starvation, their discouraged owners thinking they could not afford to continue feeding them year after year. Elsewhere in general there is a falling off in bees, and he thinks prices should not fall below those of last season.

A significant fact is that the A. 1. Root Co., which is one of the largest buyers of honey in small lots, has had no more honey offered this year than last. The well-informed beekeeper will be in no hurry to sell his honey for less than it is worth. Editor Root says:

Let me give one interesting fact in this connection. The Root Co, finds it can buy honey, from those who do not read bee-journals, at a lower figure than from those who take one or more and keep track of the market. It is not our rule to set prices. We ask for a sample and the prices asked; and it is a fact that the fellow who thinks he cannot afford to take a bee-journal will sell his honey enough lower in one season to pay for all the bee-journals for ten years.

And yet there are people who say that bee-papers are of no value to them! Of course not, if they "know it all," or are too lazy or careless to read them and profit by the information which the papers furnish.

Pear-Blight and Bees in California.

BY PROF. A. J. COOK.

THE relation of bees to the spread of pear-blight has become a very important question, not only in California but in other parts of the United States. It is now recognized that this disease, which is bacterial in nature, and is called "Bacterial Nectar Disease," exists in many parts of the country. It first appears in the bloom and is propagated by the honey bee, which spreads the disease from tree to tree. The disease is caused by the presence of certain bacteria that are present in the nectar of the pear tree and are carried by the bees to other trees. The disease is called "Bacterial Nectar Disease" because it is spread by the nectar-eating behavior of bees.

The disease first appears in the blossoms, where it may be seen as a small, round, brown spot on the petals. As the blossoms age, the spots expand and the petals become wrinkled and discolored. The disease then spreads to the developing fruit, where it may appear as a brown spot on the skin or as a dark, slimy growth on the surface.

A number of factors contribute to the spread of the disease, including the presence of infected trees, the availability of nectar-eating insects, and the proximity of uninjured trees. In California, the disease is most prevalent in areas where pear orchards are mixed with other fruit crops, such as apples and berries.

The disease is a serious problem for pear growers, as it can reduce crop yields by 50% or more. It is also a concern for beekeepers, as it can spread to other crops that are pollinated by bees, such as apples and cherries.

The disease is managed through cultural and chemical controls. Cultural controls include the removal of infected trees and the use of resistant varieties. Chemical controls include the use of antibiotics and insecticides to control the spread of the disease.

The disease is a complex problem that requires a multi-faceted approach to management. It is an ongoing challenge for growers and beekeepers, and continued research is needed to understand its underlying biology and develop effective control strategies.
partly above the water-line, and partly below, something like this:

Pure Wax.
Refuse and Wax.
Netting or Sieve.
Refuse and Water.
Water.

I said that below the water-line there would not be any wax. That is true only when by sufficient stirring and boiling the wax has had the chance, or rather the time, to disentangle itself entirely from the refuse. Now when the quantity of wax is considerably larger than the amount of refuse, all that needs be done is to take the cake out and scrape off the under part composed of wax and refuse mixed. The scrapings can be added to the next melting.

But when the amount of refuse is considerable, there is not enough wax to rise over the refuse, and the cake you take up is a mixture of refuse and wax. The problem was how to keep all the refuse under the water-line. I first melted the combs in the tin bucket with water enough to fill it about two-thirds, stirring and boiling long enough to disengage the combs entirely. I then put in the sieve made of wire-netting re-enforced by bands of galvanized iron, and fastened it there. Then I added enough boiling water to bring the wax entirely above the sieve, and let the whole boil long enough to give all the wax time to come through the netting. When cold it is something like this:

Wax.
Water Line.
Water.
Netting or Sieve.
Refuse and Water.
Water.

Some of the finest refuse came through the netting, but not enough to be objectionable.

One difficulty I met. I had to boil the whole thing quite a time in order to get all the wax to rise. After thinking about it, I concluded that by adding a considerable quantity of salt to the water the wax would rise much quicker. And it did.

Somebody may want to know how that can be. Why does the wax come on the top of the water? It is because the wax is comparatively lighter than water. That difference of weight is the force that pushes the wax above the water. That force amounts to about 3-100 of the actual weight. That is, if a vessel full of water contains 100 ounces of it, the same full of wax will contain about 97 ounces of wax. And as I said, that slight difference of weight—three one-hundredths only—is the force that pushes the wax above the water.

Now let us add, say one pound of salt to the gallon of water. The volume of the water will not be increased, but its weight will be increased by about 12 percent. That is, the same vessel which contained 100 ounces of pure water will now contain 112 ounces of salted water. The difference between the comparative weight of the water and the wax will now be 15-100 of its weight, instead of 3-100, that is, five times greater.

And the force that pushes the wax above the water will also increase in proportion, and be five times greater with the salted water.

Do you wonder now if the wax does actually rise faster when melted in salt water? Knox Co., Tenn.

Cheap Packages for Extracted Honey.

BY C. DAVENPORT.

In a previous article I mentioned that I expected to be able to use for retail trade, a package for extracted honey that, aside from the work of preparing it, would cost only about half a cent for a package holding a few pounds. At that time I said, not with much regard to the matter until I had experimented with, or tried, the package in a larger way, for as yet the whole matter is in the experimental stage with me, as it was too late in the season, or rather, my extracts were very weak and I was unable to sell my all sold last season before I thought about using these packages. Upon reflection, I have, however, decided to tell what I know in regard to the matter in the hope that it will lead others to experiment in this line.

All I have already learned is that any part of the problem, or perhaps upon further trial in a larger way some serious defects may be found about it. As the reader has probably surmised, these packages are paper sacks, and probably many of the experiment work about the grade of tough glazed manilla paper will hold, or resist the action of, honey almost as well as tin will, for how long a time I am unable to say, though the grade or kind of paper used would have much to do with this, for there are a great many kinds of paper called "manilla," many of which are entirely worthless for this purpose, and if the paper of which the sacks are made will not itself hold honey, I have found that these poor grades of glazed manilla paper are in most cases inferior to good sheet paper, to other grades or kinds of paper that are not glazed.

So far as I have gone at present I believe that if the sacks are to be waxed they are better if made out of tough, unglazed paper that is slightly porous, paper that would, when waxed, resist the action of honey for some time; again, I am unable to say how long, but certainly long enough to serve for a retail package to the producer who delivers direct to the consumer.

Whether paraffine would answer in place of wax is another thing I do not know, for I had none on hand last fall. If it would, besides being cheaper its color would make a more attractive and inviting looking package, though a waxed sack is no defective package, and the waxed sack is a clean sanitary package. Perhaps a mixture of, or preparation of, both wax and paraffine might answer better than either alone. A small amount of rosin might also be a benefit. There is a good chance that this is a clean, sanitary package and I hope that all others who experiment in this or any other way in regard to the matter will report results, whether favorable or otherwise, for it would no doubt be of interest to many besides myself. I do not have the time to deal with this small amount of the experiment work on many things in regard to our pursuit that I should very much like to do, but I shall this season try these sacks in a larger way than I did last year. I have little doubt but what they will, with me, solve a perplexing problem.

When using them, if the honey is delivered, all that would be necessary to insure their safe carrying would be to pack, or lay, the filled sacks in a large tin can or case, that has a tight cover to exclude dust. The sacks should be tied up and then wrapped, and then used as otherwise the honey would be lost. The most convenient way to use these packages, I think, would be for the producers to prepare them, or to have them prepared, and sell to the customers, who would not answer, for we would surely lose trade if we furnished a package that failed to carry safely.

To overcome this would be quite easy. I have not tried it except in a limited way, but I think whatever that this part of the system will work all right in every way. All that is necessary is to make an outer package or covering from strong cardboard, or what is called "building paper" is what I used; this is about like cardboard or pasteboard, but instead of being stiff or brittle like

The Premiums offered this week are well worth working for. Look at them.
No. 5—Some Reminiscences of an Old Bee-Keeper.

BY THADDEUS SMITH.

I have been in the habit of making such frequent visits to "My Old Kentucky Home" that I hardly feel that I have lost my citizenship there, and I have not forgotten or lost my interest in her citizens, especially those who may be classed as belonging to the former generation; and as I purpose to notice some of the more interesting reminiscences of 50 years ago, in whom I felt most interest, it is but natural that I should call up the Kentuckians first.

My neighbors, Dr. John Dillard, and Mr. D. Burbank, of Lexington, and Prof. R. A. Broadhurst, of the Kentucky Female Orphan School at Midway, were intelligent, enthusiastic bee-keepers, well informed in the science as far as it was then developed; and so was Mr. Nebbit, of Cynthiana, and Mr. W. A. Langstroth, of Adair, Kentucky, who, although he did not keep himself very prominent before the bee-keeping public by frequent communication to the bee-papers, because they had no "ax to grind" in the sale of paint to bee-keepers.

The most clever writer and original inventor of that State was Mr. D. L. Adair, of Haws ville, who contributed many interesting and instructive articles to the columns of the American Bee Journal when published in Washington, D. C. Mr. Adair had originality with a bright, investigating mind, well stored, and a fluent, agreeable way of expressing his ideas; but some of his ideas and conclusions were peculiar. For instance, he held that bees could live on the air without honey, and that they had a capacity for receiving fresh air to their compartment—that they could be sealed up tight in a box, and they would live and remain perfectly quiet without injury for a number of days. I do not remember the limit of time he gave to their confinement. I do not know how they would be affected if they were excluded from fresh air. It was a singular position to take, yet from the facts he gave and his plausible reasoning, one could hardly dissent from his conclusions. I would like to know whether others who have these ideas can have made any experiments that has ever been thoroughly tested and confirmed, or exploded.

Mr. Adair was the inventor of an original controllable movable-comb hive, quite different in principle from Mr. Langstroth's hive, or from the hives of Mr. Langstroth's manufacturers. His method was to construct sections, put together side by side and held in place by a simple and ingenious device. These sections were made of thin stuff, just as wide as the width of a comb and the space between, were placed in each, and when put together formed a box, or the hive proper—using boards for the ends. The sections were about the size of a Langstroth frame, being somewhat deeper and shorter, and could be taken apart easily, and could be used to separate sections of the hive, and the size of the hive depending upon the number of sections used. Sections were placed at each end for surplus, either for extracting or for comb honey in sections; and thus I was originated the idea of the movable-comb, or side-storing surplus arrangement. As this section hive was made of thin material, an outer receptacle had to be provided for its protection; and these were made of wood, brick, stone, or other solid material; in some cases, the section hive with its surplus receptacles, that were shoved into it through a door in the rear, and had to be withdrawn for examination.

I once made an Adair hive. It looked right; but somehow I never had the courage to put a swarm of bees into it. It remained in my honey-room for a number of years, and I kept thinking I would try a colony in it, but I never did. In comparison with the Langstroth-Simplicity, and with Smith's Simple-Combination, etc., hive, it seemed too much bother.

I think Mr. Adair really believed, at that time, that his hive possessed advantages over the Langstroth, and other frame hives. Hundreds of his hives were used in Kentucky and Tennessee, but I doubt if any one uses them now by preference.

Since I am so well known as a beekeeper, I have been frequently asked to explain my system, but I have never done so. I have spoken of it to a few friends, and they would agree that it was the best, but they both acted on the same principle—"keep the workers out!" Thirty years ago, when the country was full of black bees and comparatively few Italians, there was great difficulty in getting Italian queens purely mated, and the subject of controlling fertilization was an important one for...
the numerous queen-breeders that then sprung up all over the country, and hence many were led to experiment to get queens mated within the hive, or in some other enclosure where they could meet only selected drones. A number of persons claimed that they had succeeded in getting queens mated within the hive, and also in a tent with just such drones as they selected. But the more reliable aparian teachers did not come forward to endorse these claims, and the general bee-keeping public were slow to believe that the thing had ever been done. As the Italians increased in the country, and the black bees vanished in proportion, there was not so much danger of queens mating with black drones, and as to prevent this was then the only object of seeking fertilization in confinement, the subject was not considered of so much importance. Although Mr. N. Young claimed success with his tent, he said as far back as 1872, that he would not use his tent the next year, as the place where he intended to rear queens had but a few colonies of black bees in the neighborhood, and these few he intended to inter-convert, he would not consider it necessary to take his tent with him.

Thus the matter has been suffered to lie dormant these many years, until Mr. Hutchinson heard of Mr. Davette and his tent, and published an account of it a few months ago. It is now considered that the Italian bee itself, and probably all other races of bees, can be improved in their honey-getting qualities, and in their dispositions, by select mating; and it is claimed that a good deal has already been done in improvement of the Italians by selection of queens only, and it is believed that much greater improvements could be made if the drones could be selected also. Hence the new interest now found in this old subject of fertilizing queens in confinement with select drones. It is to be hoped that the thing will be fully and fairly tested, and all doubt removed from the possibility, or else the whole thing condemned as impracticable.

X. M. Angel was another intelligent Kentucky bee-keeper, who sometimes gave us the benefit of his knowledge through the columns of the American Bee Journal; but I have not seen his name or that of any of the others in the papers lately, and I don’t know how many of them are still alive.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marenco, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, where he will answer them, and please do not ask the Doctor to send answers by mail.—Edittor.)

Requeening an Apiary Now.

Would it be of any use to requeen my colonies at this time? Would they produce any more honey? Some of the old colonies are losing around in a listless manner, while the new swarms are working full time?

ANSWER.—It depends upon circumstances. If you requeen with better stock it would be a good thing. It is very advisable for you to keep a close record of the work of your colonies, and try to have swarms in all the colonies from those that have done the best work.

Getting Bees Into the Sections—Uniting Colonies, Etc.

1. How late in the summer do bees build comb? Is there any particular time for them to cease building? In July or August I buy colonies south of June, and they have not replaced the comb or rebuilt anything. What is the reason?

3. My bees don’t seem to take to the supers that have one-pound sections in them, where they had starters, etc. Would it be any inducement to remove everything above the brood-chamber but the super with the one-pound sections? or would a super of shallow frames filled with honey and merely left on the hive till wanted for use, cause the bees to go into the pound sections to work, giving them that much more to cover and care for?

4. Would it be a practical and successful way of uniting two weak colonies, each having a queen, to put one hive over the other; placing a piece of wire netting between for a day or night, and then let them regulate which queen they shall retain?

S. Is there any way of telling when a colony has lost its comb, and is it growing weak, without going into the hive to examine?

6. Can the presence of the moth-worms be known without opening the hive to examine for them?

MISSISSIPPI.

ANSWERS.—1. The most of the building is done during harvest-time, but there is no particular time for them to begin or quit. They will build comb whenever needed, in rare cases even in quite cool weather.

2. The probability is that it was very much coming in, and they had no necessity of filling the vacancy.

3. What you say in the previous question makes it probably that no honey was coming in, in which case they would not do anything in sections. If there was a large number of shallow frames on top, those frames being partly filled with honey, the bees would not so readily enter the sections unless they got more honey than they could easily store in the shallow frames. In the same way, if a super of sections partly filled were on the hive, they would not touch another super of empty sections. But if you remove the super of shallow frames, the bees will begin on the empty sections sooner than if the frames had not previously been there, always providing any honey is coming in. In this case, it will be taken, in working the whole hive, and you will be safer against fighting if you remove one of the queens a day or two in advance. There must be an entrance to both upper and lower hives.

4. Not for certain.

6. Not certainly. If you see worms dragged out, you will know, but you don’t always see that.

Late Wax-Secretion and Laying Flying Drones.

1. How late in the fall can bees make wax?

2. How late does the queen lay eggs?

3. Is it profitable to kill the drones now when we want no more swarms?

ILLINOIS.

ANSWERS.—1. Very late if it is necessary, although there is generally no occasion for it. I think bees might be forced to secrete wax in the middle of winter.

2. The time varies greatly. A queen may stop laying in September, or she may continue till frost. Much depends upon the yield of nectar. Sometimes queens continue to lay although no brood is reared. If the honey production there be very small generally superimposed on top of frames and sealed brood in the hive, but no unsealed brood. The queen keeps on laying, but the bees do not take care of the eggs; perhaps eat them. My place is in the region that suffered so terribly from the July drought, and brood-rearing was almost entirely suspended, although the queens continued to lay. In some hives were found neither sealed nor unsealed brood, although eggs were always present. If I had been a better bee-keeper, I suppose I would have fed to keep up brood-rearing (I did later on), but I had never had such an experience before, and was expecting a change every day.

3. Yes.

A Beginner’s Bunch of Questions.

1. I use the 8-frame hive. I have only eight colonies of bees, having bought five last spring, all Italians. I had two hybrid colonies. Now there are four hybrids. Is there any way to keep these colonies in line for becoming hybrids?

2. Can I breed them back and make them all Italians again? If so, how?

3. I haven’t had any swarms issue yet. They are all strong, and working well. What is the cause of their not swarming?

4. What is the best time of day to rob the bees?

5. I would like to increase my colonies to 15 or 20. As they will not swarm, what and how shall I do? Is it too late now to transfer? The cotton-boll hive has four main honey crops.

6. What is the best way to catch the queen and handle her without hurting her?

7. How many colonies can one man attend to?

8. How much honey is it expected that a strong colony will store in one season?

TENNESSEE.

ANSWERS.—1. So long as there are black or hybrid bees within two or three miles of you, the likelihood is that most
of your colonies will be of mixed blood. Rear from pure stock each year, and eventually you may work out the black blood.

2. As in the previous answer, your most hopeful plan is to raise your own queens from pure stock, and when you run out of pure stock get a pure queen. A careful study of your text-book may be of some help.

3. Hard to tell. Possibly they are not getting enough honey.

4. Right in the heat of the day, when the bees are busy at work. If there is danger of robbing, however, it may be better to take away the honey in the after part of the day, so that darkness may cover any tendency to robbing.

5. It is difficult to advise just what is the best way for you. If you will carefully study your text-book you will probably be better able to judge for yourself. One way is to take all but one frame from the hive and put them in a new hive on a remove the honey from the old stand. Let the queen on the old stand. Let all the adhering bees be taken with about half the frames, and shake off into the old hive the bees from the other half. It is not too late to transfer.

6. Catch her by the wings or by the thorax (what, perhaps, you would call the shoulder)—never by the back part or abdomen.

7. Probably five colonies are as many as would be wise for you to have till you gain some experience. An experienced bee-keeper may care for 100 colonies or more. A few very old and vigorous bees I do think the drones are the ones we ought to be particular about. I think if we can get our bees, queens and drones all with the same marking, we will have better bees and more honey, as my experience of about 20 years with bees has shown.

**The Afterthought.**

**The "Old Reliable" seen through New and Unreliable Glasses.**

By E. E. Hasty, Sta. B Rural, Toledo, O.

**Gardens for the Children.**

Ancient page 409, where Prof. Cook talks of a garden for each child, there are two children at the home in which I live. The ground is made up of plots of land, but seems to me almost idiocy as to the details of the matter. Surely, I thought, it would be no use to give them gardens. Well, this summer their father took it into his head to do just that. And he didn't give them little and worthless bits, either, but large plots of very fertile ground. The result is that with a very moderate amount of advice and assistance they are having some success. Their crop will not total much in money; but when we come to consider things worth more than money, no equal area of the farmyard produces so much. Had the plots been smaller, so as not to oversize the amount of hoeing they enjoy doing, it would have been a little better.

**A House-Cellar for Bees.**

Some have doubted whether a house-cellar, with footsteps and children's play immediately over the bees, could be anything else than a very poor place to winter bees in. As a counterblast to this it is interesting to see that the Gleanings, in a machine, overhead, proved a first-rate place. The fact seems to be that bees will get used to almost anything if it is only experienced hourly or very frequently: but when noise or jar occur irregularly, and not much often than once a week, then they are disturbed and injured. Page 413.

**Queen Fertilizing Eggs.**

F. Grether may be right, page 420, that the queen fertilizes eggs, or omits to do so, entirely without volition. Something other than space, or curvature of the queen's body, may deeply affect the activity. I opine, however, that a "straw vote" would show him badly in the minority.

"Jouncing" Extracting-Supers.

I don't want to make sport of any manipulation which a practical brother finds to succeed even tolerably well. If I did I might try to be funny over Mr. Davenport's method of jouncing out the bees of an extracting-supers. I'll be respectful; but I'll wait till a lot more of the brothers find it a success before I Jouncer. Page 420.

**Swarms Going Back.**

Tell Dr. Miller, page 425, that among Ohio bees more than two swarms go back to the old hive after hiving, for each 95 that go to the woods. Of unmixed swarms, with laying queens, and the queen all right, perhaps his proportion would answer. Swarming and going back into the old hive again has been abnormally rare—going back before clustering, and going back after clustering, and going back during attempt to hive, and going back after hiving—all sorts of going back. When bees from different hives get mixed in swarming (a very common thing in large apiary with swarm-fever raging) the queen or queens will often be balled—at least half the time if the bees are light of honey—which is also a common thing, at least in this yard. The little ball of bees and queen often falls from the cluster to the
ground, and is liable to be left unnoticed. Then, of course, the queenless bees go home, either before or after hiving. Sometimes the ball is formed after hiving, or deposited with the pollen. Then the bees go to the wind and carry off where they run in. In these cases also the bees go back to the old hive—never to the woods. I think. While we are on the subject of swarming let me "swat" another old and popular fallacy—the idea that if you do it with honey, you can prevent it. They go just as they happen to be. I am pretty well convinced. A swarm imprisoned will sometimes quickly begin to die of starvation. On the other hand, after three days and two nights of imprisonment, they will almost always build a good pieces of comb and have a honey flow in it. This imprisonment trick is a hobby of mine, and thus I know.

WINTERING OF DIFFERENT STRAINS OF BEES.

I suspect it is easy to be mistaken when we say that one kind of bee winters better than another. In a mild climate, however, which may happen nevertheless to be a climate in which staying quietly indoors is much more profitable than bustling around, it is reasonable to expect that blacks might winter better than Italians. But, Mr. Whitcomb, mightn't a poor and lazy strain of Italians idle and prosper just as well as a blacks could do? Might not prosper as well next June, eh? Then I guess you're pretty much altogether right. Your fourth point is hardly important enough to rank with such important things as the first three points comprise.

The Home Circle.

Conducted by Prof. A. J. Cook, Claremont, Calif.

STRAWS POINT THE WIND.

We all court or desire popularity. Few of us get it in as generous proportion as we would, and so we are inclined to be a little envious of our friends whose not only love and admire, but who are general favorites. Everybody is quick to take them up, and even more slow to let them slide out of their social circle. I have often thought, and as frequently said, that two fortune could be justly said to out-rank that of having for our life's work that which we enjoyed most to do. It is almost as beneficent and helpful to be attended in our life-journey by those who admire, respect and love us, and who are ready to trust us with their lives, as it is to be in the habit of being used, and tenfold. I know of no thing that gives such full satisfaction as the sure thought that those who know us best believe in us. There is no show of wavering in their faith.

We all have known public men whose presence among their neighbors and friends is sure to bring loud acclamations. They are ever greeted by their constituents with loud and heartfelt cheers. All this is most grateful to him who is so happy as to receive it, and must be a most potent influence, not only in making the life more pleasurable but also in causing to yield richer and more abundant fruit.

So great a factor in the happiness and success of our lives is well-earned popularity, that we are all wise to study the ways and lives of our most esteemed friends, that we may, if possible, differ as few as possible from them. We may strive with unabated effort to crown our own lives with like virtues. Life-furnishes most excellent opportunity for such study. The "straws which point the wind" are ever in evidence.

We are in camp. Many other campers are near neighbors. The meals are to be provided: the wood chopped; the dishes washed; the camp to be kept neat and tidy; not only our friends, but other who have not such evident claim on us are, or ought to be, entertained. The books brought to camp are very entertaining; the many magazines abound with fascinating recitals or stories; special friends are so attractive; how much there is to make selfishness assertive, how many straws will show the trend of character.

Here is where the one who has grown into a life of thoughtfulness for others shines forth as the noonday sun. Such a one takes no heed to find the exact bounds of his allotted tasks, but is ever reaching out to make others happy, instead of laying the burden on one. He is quick to lay aside the entertaining story to help some other in a wearying task, or to entertain some older person, or, possibly, some visitor who has come to the camp for a recreation which the home camp has failed to furnish.

Some one in camp has been off on a long tramp, climbing the ever-aluring mountains, or seeking some pool where the trout are more or less reluctant to bite. Yet it is to see that the meal is prepared, or the wood chopped, or the dishes washed. The dragging step and tell-tale pallor are quickly noted, and he finds his work is snatched from his tired hands, by those who have learned of thoughtful unselfishness. It is a rare thing, and tells a whole chapter of character trend, which ever charms, wins, and sweetens. If one ever gets just "dead tired" and "dead gone" with hunger, his Tranquility is in the habit of bringing trout, honey, or bread from the deep, wooded canyons, or climbing the steep mountains, where lured on by beauty and awful grandeur the tramp carries us often away beyond our strength, and yet we must retrace our whole rugged journey because of the good food possibly before water—can bring the longed-for refreshment.

Here is where the Mark Tapleys shine out.

"OLD BALDY" (San Antonio Mountain).

Where is it? and what? It is one of the three highest peaks of the Southern California mountains. It reaches up 10,000 feet, and lies 23 miles north from Claremont. It is 16 miles west of our camp, which is something over 3,000 feet above the sea-level, and for miles we may see the tall graceful forms of whom won ladies. Horses or mules, and one pack-mule, carried us and our belongings 12 of the 16 miles. Then we must walk and carry our food and blankets, for we must sleep that night on the very crown of the lofty summit. What a climb—1000 feet or 1000 feet to the mile! Two and one-half miles more on the very ridgepole of a great roof-like mass of granite—a mere narrow path often hardly a foot wide, and steeper on each side than steepest roofs; often almost perpendicular. All have adored and5 ever the mad, 1000 feet—more than one-fifth of a mile. Often this path stretched upward as fast as onward, and yet our party hunched not, but all slept that night on the very crest of this grand mountain peak. Only one took to hands and knees, and she but once. But more than one wondered if they could do it. And almost all drew long breaths as the most trying points were scaled. So rare was the air that ever and anon all would pause to draw a half dozen quick breaths in rapid succession, before resuming the ascent.

It was a tremendous climb but the outcome warranted the labor, the fatigue, the trepidation of fright, for the outlook from the crest, as also the sunrise, were entirely indescribable. I if one ever seems right in God's very presence it is while on some such top. BALDY, as the mountaineers call it, is surrounded by a boundless, varied, far-reaching landscape, I uttered the truth that I would rather have given $25 than to have had my daughter miss the experiences. She made the trip with easy, lightsome steps, and hardly knew her weakness till the race the bald summit; with a good camp-fire and our blankets we kept the chill away, and slept some.

At 5 a.m. we enjoyed the transcendent sunrise which alone paid for the journey. We were precociously seated, and had camped at 12:30. Oh, we were so tired! All our party kept their cheer, their smiles, and their tempers. I heard all by my own tired muscles, and was prouder that I had such friends and comrades. Those light of weight, and used to every kind of toil and weakness.
ADVERTISEMENT.

To Our Shippers:

We were obliged to notify you a few weeks ago that one Joseph M. McCaul had leased our old quarters at Nos. 120-122 West Broadway, New York City, and had there started up business under the name "HILDETH, McCaul Co.," and had distributed a multitude of circulars so worded as to create the impression that his business was a successor to or a branch of the business of Hildreth & Segelken.

For the protection of our shippers and ourselves, we at once instructed our attorney to commence action to enjoin the said McCaul from using the name HILDETH in any manner whatsoever in connection with his business. On the 10th day of July, 1901, Hon. David McAdam, Justice of the Supreme Court of the State of New York, after a full argument upon the merits, issued a peremptory injunction, of which the following is an extract:

"And it appearing that the plaintiffs have for a long time been and now are carrying on business under the style of 'Hildreth & Segelken,' and that the defendant has recently opened a business at 120-122 West Broadway, in the Borough of Manhattan, City of New York, and is carrying on the same under the style of 'Hildreth, McCaul Co.,' and that such act is in violation of the plaintiffs' rights, and that the commission or continuance thereof, during the pendency of this action will produce irreparable injury to the plaintiffs: it is

ORDERED that the defendant (Joseph M. McCaul) and each of his agents, servants and employees and all other persons acting under his authority and direction be, and he and they are hereby restrained and enjoined from showing, displaying or otherwise using during the pendency of this action in or upon any papers, devices, sign or signs, or otherwise, in the business conducted by the defendant at No. 120-122 West Broadway, in the Borough of Manhattan, City of New York, or elsewhere the name of "Hildreth" separately or conjunctively with any other name, designation or description."

Outside of our desire in our own interests to protect the name which we have built by years of satisfactory dealings with our customers, we hastened to procure this injunction as soon as possible, to prevent our shippers from being misled into sending their goods to one who would make an attempt to gain their trade by such a trick and device.

With thanks for the many expressions of good-will we have received from our shippers concerning this attempt to trade under our name, we are,

Sincerely yours,

HILDETH & SEGELKEN,

265-267 Greenwich Street, NEW YORK, N. Y.

Is the "Wide-Open" Fair a Financial Success?

The Civic Committee of Boston has sent a series of questions to all the State Boards of Agriculturists, asking whether, in their opinion, the purely legitimate Agricultural fair or the "wide-open" fair is better in the long run financially, socially and educationally. Opinions in reply have been received from all the States, including two Provinces of Canada.

Without exception these officials say that the purely legitimate Agricultural fair or the "wide-open" fair is better in the long run financially, socially and educationally. Opinions in reply have been received from all the States, including two Provinces of Canada.

They are also unanimous in rigorously excluding all games of chance; for strictly prohibiting the sale of alcoholic liquors except in the States; and they severely condemn vulgar tent-shows and suggestive demonstrations on the outside of tents.

As to whether "circus" features tend to absorb time, strength and interest of patrons to any disadvantage, the exhibitions of farm, home, school and factory products, the majority believe that they do, and therefore should be encouraged. Queen of the writers lean to the view that entertainments, those foreign to the real features of the fair, should be done away with as fast as the people can be educated to appreciate the fair for its own sake. The Civic Committee.

Very Dry in Idaho.

It is very dry here now; but the bees are doing some great work on clover, buckwheat, and buckwheat. I have nice, strong colonies from two colonies I purchased a year ago. I try to prevent swarming as far as possible, but use X-frame hives, but the best helper I have is the American Bee Journal.

Good Season for Honey.

I am a beginner in the bee business, and hope, in time, to make a success of it. I worked for six months, and I do not expect to get much honey, although this has been a great season for honey here. There is an abundant supply of sweet clover, and the bees are working well. I hope and expect soon to be a member of the National Bee-Keepers’ Association, as I think it is a worthy cause.

L. C. Larken.

Will Co., Idaho, Aug. 6.

Building a Mouse-Proof Honey-House.

G. M. Doolittle tells how to build a honey-house, on page 436, emphasizing the necessity of having it mouse-proof. I think I can tell the readers of the American Bee Journal how to erect such a building and have it mouse-proof without the trouble and expense of "fitting it with tin," and I can do it best by telling how I built my own.

After laying the sills on good-sized rocks, then nailing and nailing with the sills in place, I then laid the floor—good, matched material, free from knot-holes, and kild the joists all around; then spiked 2 x 4 scantling flatwise on top of the floor cleat around the outside, like a plate; then nailed the siding to the cleat, covered it with good, matched drop-siding, painting the tongues with thick paint as fast as it was put on.

The building is provided with five windows and a door, a door, all provided with screens, the windows and door, and have them glassed for summer and winter, so that if the door is care-
FOR SALE

3.5 acres, well suited to cherries, peaches, plums, pears, apples, currants, raspberries, blackberries. Good house, barn, vegetable green-house, house, 50 or 100 colonies of bees, situated in good bee-locality. Title clear. For further information, write A. L. KILODOW, Sheffield, Ill.

Farm Wagon Economy.
The economy of this proposition is not all found in the very reasonable price of the wagon itself, but in the great amount of labor it will save, and its great durability. The Electric Wheel Co., who make this Electric Handy Wagon and the now famous Electric Wheels, have proved the value of a successful and durable low-down wagon at a reasonable price.

Write for catalog of the full "Electric Line" to Electric Wheel Co., Box 6, Quincy, Ill.

FREE as a ....
A Foster Stylographic Pen....

This pen consists of a hard rubber holder, tapering to a round point, and writes as smoothly as a ball point. The point and needle of the pen are made of platinum, alloyed with iridium—substances of such great durability which are not affected by the action of any kind of ink. They hold sufficient ink to write 10,000 words, and do not leak or blot.

As the best line of uniform width at all times they are unequalled for ruling papers. Pens are furnished in neat paper boxes. Each pen is accompanied with full directions, filler and cleaner.

BEST Mail-Order Pen on the Market.

19,000 Postmasters use this kind of a pen. The Editor of the American Bee Journal uses the “Foster.” You should have one also.

How to get a “Foster” FREE.

Send two new subscriptions to the American Bee Journal for one year, with $2.00; or send $1.00 for the Pen and your own subscription to the American Bee Journal for one year; or, for $1.00 we will mail the pen alone. Address.

THE MULBERRY AS A HONEY-PLANT.
Do you believe in telepathy? Then how do you explain the fact that since I accidentally started a mulberry tree from a mulberry bee-food for honey-producing—before the article in reference to mulberries had appeared in the American Bee Journal—over 400 enquiries have been received, special explanations being desired?

If the editor will permit me space I will cheerfully add the result of recent and more extended experiments. I should have been more explicit in some of my details in the first article, to which I will advert in this.

I am not certain as to how large dimensions the white mulberry l. and its kind.

I know, grows to be large, in some sections used for saw-logs, but the white may not

A HANDY TOOL-HOLDER!

Sent by Express, for $1.50; or with the Bee Journal one year—both for $2.00.

Every Manufacturer, Miller, Carpenter, Carpenter, Mason, Mason, Mechanic, Wheelwright and Farrier, or any one using a grindstone, should have one of these Tool-Holders. One boy can do the work of two persons, and grind much faster, easier and with perfect accuracy. Will hold any kind of tool, from the smallest chisel to a draw shave or ax. Extra attachment for sharpening scythe, knife, or saw blades is included in the price above. The work is done without wetting the hands or soiling the clothes, as the water flows from the operator. It can be attached to any size stone for hand or steam power, is always ready for use, nothing to get out of order, and is absolutely worth 100 times its cost.

No farm is well-equipped unless it has a Tool-Holder. Pays for itself in a short time.

How to Use the Holder.

DIRECTIONS.—The Tool is fastened securely in the Holder by a screw-screw and can be ground to any desired bevel by inserting the arm of the Holder into a higher or lower notch of the standard of the holder. While turning the crank with the right hand, the left one does all the work on the holder. The holder is turned to the right or left across the stone, or sharpened while grinding, as readily and in the same way as it is held in the hands.

For grinding Round-Edge Tools, the holes in the standard are used instead of the grooves.

GEORGE W. YORK & CO., 111 & 114 Erie St., Chicago, III.

As to Editors of Bee-Journals,

It seems to some a matter of reproach that editors of bee-journals are not completely informed on all topics relating to the subject. The subject is a big one, and it is impossible to keep up with all that is new. If the editor is not completely informed, it is not reproach in itself. The editor must be careful to keep the journal free from errors and to keep it as current as possible.

Red Clover—How Important is It?

The desire to obtain the nectar secreted by red clover is one of long standing; and the common impression is that a very large quantity of nectar per acre would be secured from it if the flower-tubes were not too deep for the bees. Actually, such a credit has been cast upon red clover as a honey-plant, even supposing that all its nectar might be found to be utilizable, that it is not a plant of universal cultivation.

There are a few plants that yield an enormous quantity of nectar, but as they are not only in greenhouses, averaging less than one plant to the acre, they are valueless from a bee-keeper's standpoint. If, however, any good honey-yielding were widely distributed in dense quantity over a single State, then it would assume some degree of importance. The buckwheat crop of the State of New York would be of trifling matter, even if not another acre of clover that were found wherever the United States. It was impossible to obtain certain bees that would double the buckwheat honey crop of New York, the amount of money gained by that would warrant no small outlay. It is not possible that there are single States in which the nectar will be distributed in such a way as would amount to several thousand dollars.

But is red clover confined to a rather limited area? It would be interesting to know just what is the average acreage. Lacking that, some estimate may be made from the amount of clover seed raised. The government statistics give us the figures, and it is probably safe to infer that by "clover seed" is meant that from red clover. According to the last census available, that of 1890, an amount of clover seed, large or small, is given as being raised in every State and Territory of the United States except Montana and Wyoming. Certainly that shows that it is not confined to so small an area.

The North Central division leads with a product of 2,244,904 bushels. The South Central comprises 1,175,718 bushels; North Atlantic, 71,128 bushels; South Atlantic, 39,156 bushels; Western, 21,350, Total, 3,756,581 bushels.

That shows a very unequal distribution; but this distribution of the growing plants is by no means what it would be. From the States that are the greatest producers, as New York and Pennsylvania, large quantities of hay, and, of course, States import, thus making the acreage grown in the different States much more uniform than the seed produced.

If all the seed raised is sow said—and it is not likely that it is ever used for any other purpose—and if a yoke of seed is sown to the acre, it would cover a little more than 11,000,000 acres. To speculate as to the amount

FREE FOR A MONTH ....

If you are interested in Sheep in any way you cannot afford to miss the "White Clover" Sheep Paper published in the United States.

Wool Markets and Sheep has a hobby which is the sheep-breeders and his industries. We get our information from the latest publications, and from all the time. Are you interested? Write to-day.

WOOL MARKETS AND SHEEP, CHICAGO, ILL.

We arranged with one of the oldest and best queen-breeders (having many years’ experience) to rear queens for use in the United States. His bees average a little more than 1 gallon per month, but, in the good deal the longest tongues of any yet measured. The Breeder he uses is direct from Italy, having imported her himself. His worker-bees are large, some what tardy, but keep their honey and syrup well.
of honey that could be obtained from this acreage would be outside of the present inquiry, and it is doubtful as to there being sugar maples in this vicinity, and a reasonable estimate is only desired to show that the aggregate of red cedar territory is large enough to warrant the expenditure of $1,000 and that it is widely distributed. Gleanings in Bee-Culture.

**Distance of Apiaries.**

At a conference of the Victorian Apiarists’ Association, it was agreed that, under any existing conditions, even if brought back by mutual consent and purchased by some one party to the executive of the Association, no reservation of any member’s apiary by mutual consent, and that to observe this rule, should be adhered to by all. The following is a reproduction of the resolution:

"All the member practicing production of the
products of the apiary, or guilty of fraudulent pressings as a bee-keeper, should be disqualified."

It was pointed out by one and another that the best members of the bee-keeping club were crowding close to another apiary, often of superior numbers, was made by one that the bee-keeping club was the best, so that no effort was made by anyone who had not the moral sense of honor and fair play, and that the members should be kept in keeping at a fair distance from their neighbor. Several bee-keepers thought the distance between their hives apart, and no doubt was expressed that this is in all but the very best of bee-country quite close enough. A man never says as much as he does of bees of the season is very much too close for apiaries of any considerable size.

**The Bee in Law.**

Under this caption has begun in Gleanings in Bee-Culture a series of articles by F. D. Fisher, with a view to having them afterward in a similar form, so that the bee-keeper may, will serve a convenient purpose, especially as laws of different States are by no means alike. As to ownership, Mr. Fisher says:

With regard to bees, Blackstone, the great lawyer-giver, says: "The bees are mere naturae (wild by nature), but when hived and reclaimed, a man may have a quality possessed in them by the law of property, giving them to himself at the law.

And to the same purpose, not to say in the same words with the civil law, speaks Bracut: "Occupation, that is, hiving and includ- ing the bees as his property, makes him the owner of them."

For, though a swarm alights upon my tree, I have no more property in them till I have hived them than I have in the birds which nest thereon; and, therefore, if another hives them, he shall be his proprietor; but a swarm which flies from one of my hives, and so long as I can keep it in sight and have power to purses them, and in these circumstances no one else is entitled to take them."

But in respect to such animals as are in the habit of obtaining and placing in their hives, a large number of which, which are accustomed to go into the woods and fields, and come again, we have no right to own them if they come again. They have the right of returning, and if they return in search of the intention of returning, they also cease to be ours, and become the property of the first house that they come to."

"It is a fine thing to preserve the copies of the Jour-

nal as fast as they are received. If you have this "Emerson" so further binding is necessary.

More Bee-Keepers’ Paradies....

E. R. Root has just returned from a 6,000-mile trip through some of the best bee-locations in the world, and has already begun his series of write-ups, accompanied with fine photos, in Gleanings in Bee-Culture. The following editorial appears Aug. 1, and will give something of an idea of what he will describe:

Some little time ago I promised to tell about the bee-keepers’ paradise in Texas. I have this on the docket, and it will appear as I take up the line of my travels. But since running across that paradise I have run into two or three others. There is one west of the Rockies, in Colorado, that is not yet overstocked with bees or bee-keepers; another one in Central Idaho—in fact, I do not know but the whole State. These will be described in turn. The fact is, millions of capital are being invested in irrigation; irrigation means alfalfa; alfalfa means a paradise for bees. But I found all along my trip that alfalfa-growing preceded bee-keeping by two or three years, for it seems to take about that length of time before bee-keepers find these gold-mines that have been hitherto unoccupied.

If you are dissatisfied with your present location, and for financial reasons, or on account of health, will be compelled to leave, subscribe for Gleanings in Bee-Culture, and learn something about the great South and the great West. There are many locations in the West that are not yet occupied—splendid bee-locations. If you wish to learn about them, send 25 cents for a six-months’ trial subscription, or $1.00 for one year and one untested Italian queen. Or, send $2.00 and we will send Gleanings one year and one of our celebrated Red Clover Queens.

THE A. I. ROOT CO., Medina, Ohio.

GEORGE W. YORK & CO. 144 & 146 Erie Street, CHICAGO, ILL., are headquarters for Root’s BEE-KEEPERS’ SUPPLIES in Chicago. Send to them for their free Catalog.
TWO PAN-AMERICAN BUILDINGS.—See next page.
Weekly Budget.

CLOSED SATURDAY AFTERNOONS. — It seems that some of our customers have forgotten that our office and store are closed Saturday afternoons from July 1 to Oct. 1.

MR. E. M. HUNT, son of M. H. Hunt of Wayne Co., Mich., was married to Miss Jessica Sawtell, Tuesday, Aug. 13. Heartiest congratulations to them.

ON TO THE THOUSAND. — Still they come — those who are helping to make up the first 1000 members of the National Bee-Keepers’ Association. These names have come to this office, with the dollar each, since our last issue.

GEO. W. HARRISON, JOHN CONSER, FRANK L. GOSS, THEO. J. WOODWARD.

MR. H. W. CONGDON, of Hardin Co., Iowa, called on us Aug. 9. He was on his way to Buffalo, to visit the Pan-American Exposition, and also his parents who live near there. Mr. Congdon has between 40 and 50 colonies of bees, and hopes next year to establish out-apiaries. This crop this year, owing to the drought, has not been very much. Still he is not discouraged.

DR. WILLIAM CRENshaw, of Fulton Co., Ga., dropped in to see us Friday, Aug. 2, when on his way home from the national meeting of the dentists of America, at Milwaukee. Dr. Crenshaw has about a dozen colonies of bees, and is doing nicely with them. Of course, he keeps them more as a pleasurable pastime, in connection with his profession, rather than as a source of financial profit. The Doctor is a very pleasant gentleman to meet. Succeeded to him.

MR. N. E. FRANCE, of Grant Co., Wis., inspector of apiaries for that State, will be the judge of the apiarian exhibits both at the State Fair in Milwaukee, Sept. 9 to 12, and at the Fair at Platteville, Sept. 17 to 20. The judging will be well done, and all will be satisfied.

Mr. France says he has been quite busy treating foul brood, and has had many obstacles to overcome the past year. But he says further that he has now gotten the disease pretty well stamped out of the State, and all remaining cases under quarantine control.

Oh, that every State had a bee-inspector, and every one equal to this one with a French name!

PAN-AMERICAN BUILDINGS. — On the preceding page we show two of the many beautiful buildings of the Pan-American Exposition. The Agricultural Building contains exhibits of agricultural products, processes and articles pertaining to the farm, of the most interesting character. In these days of scientific farming the successful agriculturist finds it necessary to acquire a fair knowledge of many of the sciences. The agricultural exhibits show many of the wonderful possibilities in farm work.

At the Pan-American Exposition, as we understand, are shown the largest display of electrical machinery and appliances ever presented. Nearly every article in the very latest design, and the visitor will find novelties without number in this interesting division. The Electricity Building is of very rich and beautiful design, having a broad loggia on the southern side, while the roof-line is broken with domed towers.

Doubtless many of our readers will have an opportunity to see the Exposition while attending the annual meeting of the National Bee-Keepers’ Association at Buffalo next month — Sept. 10, 11 and 12.

HE WORKS STANDS. — In one of the recent issues of a certain bee-paper an old and experienced writer says, “I work 200 stands.” Just think of working the “stands!” Wonder what he does with them? But quite likely he meant colonies instead of stands. It’s almost beyond understanding how one bee-keeper can stand around and still talk about their stands of bees. Or, perhaps they’ll say they had so many hives in the spring, and increased to twice as many “hives.” They don’t say whether they bought the extra hives from some bee-supply dealer, or got them by “in-breeding.”

Of course they mean colonies, and not “stands” or “hives.”

A BADGE PIN for the members of the National Bee-Keepers’ Association is thus suggested by Mr. N. E. France:

“I wish the National Bee-Keepers’ Association would adopt some design for a badge pin, and every member have one to wear. The one used at Chicago is good enough. I could relate several instances where persons have asked what that bee-keeper’s badge represented. (I wear one all the time.) I answer always, ‘National Bee-Keepers’ Association.’ In one case I was called to settle a dispute about bees, and was introduced as State Inspector and member of the National Bee-Keepers’ Association. The fact that I belonged to said Association seemed to settle all dispute, and both were willing to leave their troubles for another day, and most of them belonged to the State or National organization of bee-keepers, but they will join them both at our next meeting.”

Harrah for a badge pin for the members of the National Bee-Keepers’ Association! Why not adopt one at the Buffalo meeting? True, the badge pin used at the Chicago convention last year is all right. Why not adopt it?

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with order, post age free.

<table>
<thead>
<tr>
<th>Description</th>
<th>Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sweet Clover (white)</td>
<td>$1.00</td>
</tr>
<tr>
<td>Sweet Clover (yellow)</td>
<td>$1.00</td>

Editorial.

Beware of Honey-Dealing Frauds!—Such caution, not many years ago, was absolutely necessary. It was our privilege, as well as enthusiastic pleasure, to help drive out of business a few of the most daring honey-sharks that ever "sharked." And so far as we know they are not "sharking" beekeepers now, we are glad to say. Many of our readers have at least peculiar reasons for remembering the Horrie-Whalen-McConkey crowd that a few years ago so successfully fleeced the unsuspecting honey-producers, here in Chicago. Just now we are not aware of any here that are getting ready to "do up" the "easy" bee-keeper. And yet it is always well to be on one's guard, for no one knows just when the wolf will show his claws through his sheepish covering.

It is a pretty good rule to make a thorough investigation before shipping honey—or anything else, for that matter—to new firms or strangers. The facilities are fairly ample in these days, to learn of the financial responsibility and character of those who solicit the products of the apiary and farm. Also, it is generally true that an old and established firm can do as well, if not better, with any produce entrusted to them, than can new firms. At any rate, we should hesitate a long time before changing from "the old and tried" to the new and untried. The latter may be all right, of course; and then, again, they may not. But if you must experiment with new dealers, our advice is to ship no more at a time than you can afford to lose— until you are satisfied they are honorable and satisfactory in their business conduct.

We can assure you that it isn't pleasant to feel the necessity of giving such caution as the foregoing, as it may be an injustice to some splendid new firms; and yet, the good and well-meaning must sometimes suffer on account of the fraudulent actions of those for whom they are not in any way responsible. But such is the stern law of public trade and dealing. It is hard, and yet there seems to be no other safe way of escape.

Seasonable Articles, that are articles given at the right time for putting into practice the suggestions contained in them, have been strongly urged at times. What is the use of giving advice about a thing just as the time of year has ended when that advice can be put into practice, and nearly a year must intervene before the next opportunity to try it? In spite of that, F. L. Thompson advocates in the Progressive Bee-Keeper that the close of the swarming season is the best time to discuss the swarming problem. And he gives reasons for it that are not to be despised. Right when a thing is yet fresh in mind with all its particulars is a better time to give it than to wait till particulars are partly forgotten, and enthusiasm has died away. One or two bees at a time are allowed to escape, in many cases, if not in most cases, the bee-keeper concludes he will not write at all.

A horticulturist once gave as a rule for the best time to prune trees. "Prune when your knife is sharp." It may be a good thing for the readers of this journal to follow something like the same rule.

Whenever you have any item that you think would benefit some other bee-keeper, sit down right and write it off, in season or out of season. Sometimes some little thing will be learned, and just because it is a little thing it is not thought worth while to send it. Bee-keeping is largely made up of little things, and many a beginner strikes upon a little thing that some of the veterans have not yet learned, and will be glad to know.

When you have gained some new light, send it in. If it is something that is so generally known that it is not worth while to print it, you need not feel hurt that it does not appear in print. But the danger of that is small. A good many things bear repeating.

Don't be afraid to add your mite.

A Novel Method of Feeding Back to get unfinished sections completed is thus given in the Bee-Keepers' Review by Fred H. Fargo:

The honey to be fed back, which may consist of unfinished sections, or any combs of suitable honey from three to four pounds in quantity, is daily placed in a hive (the entrance to which must be contracted to admit two bees at a time), and a few rows from the apiary, and not a great distance from the colony upon which are placed the unfinished sections to be completed. A section of honey, bruised so that the honey is ready to run, and covered with bees, is then taken from the colony upon which are the unfinished sections, and placed in the hive containing the honey to be fed. Or, we can place a section or piece of comb honey on the alighting-board and leave it there until sufficient bees from this colony are taking the honey, then place in the hive as above stated. These bees, thus carried from their home and placed in a hive containing honey, will work back and forth between this hive and their home, carrying the honey to the last and the strange part of it is that they will defend both hives from robbers.

In selecting the colony to do this work, choose one containing good workers that will protect their own home against the intruding robber-bees. The fact that the work of carrying away the honey is commenced by bees that are all from one colony accounts for their combining in a defense of the spoil.

Commenting upon this, Editor Hutchinson says:

"If one had broken pieces of comb honey, that method might be all right; but for the feeding of extracted honey I think that I should prefer a regular feeder that could be set upon the top of the hive in which the work is being done."

It is barely possible, however, that in some cases there would be an advantage in Mr. Fargo's plan, even if the feeding were done in the usual way. It is probably always the ease that when there are sections to be finished, there are at the same time sections that contain only a small amount of honey, that amount being so small that instead of trying to get them finished by feeding back it is better to have them emptied out by the bees so as to be used as baits the next season. If it is true that in all cases the bees will defend the robbed pile as Mr. Fargo says (there seems some reason to believe it when it is remembered that there is often severe fighting among robbers), then two birds may be killed with one stone. When the light sections are put in a pile to be emptied out for baits, as is the practice of many, instead of letting all the bees of the apiary work upon them, just take Mr. Fargo's plan, and let the honey be all used by one colony.

Washing Black Combs.—It is well known that combs become black with age, especially those in which brood is reared, but it is not so generally known that when such combs are dipped with water and allowed to stand a few days the water becomes inkly black. It is reasonable to suppose that when so much of the dark color is soaked out by water, at least some of it will be absorbed by honey, hence it has been the practice for some time, when a choice article of white extracted honey was wanted for show purposes, to use only new combs for extracting. It is suggested in Gleanings in Bee-Culture that the same end may be reached by washing the coloring-matter out of the old combs. "Lay the combs flat, fill the cells with water from the nose of a watering-can, then after soaking throw the water out with an extractor."

**Making Swarms—How It Is Done.**

**By Dr. E. Gallup.**

On page 47n, is an extract on "Close Imitation of Natural Swarming," by G. M. Doolittle. A Langstroth hive makes a very convenient box with the entrance closed, and a board nailed on the bottom, for a clustering-box. You can set up the box open side outward, and let the bees come in the bottom and make the box, instead of waiting for them to run in, as in hiving. They will begin to cluster at the top end of the box at once. If you have two or more swarms come out at one time and crowd together, you can make a second swarm of more queens than one, and you wish to separate them, shake them into the clustering-box and let them stay for half or three-quarters of an hour, and the bees will fill the surplus queens, and roll down to the lower edge of the box, and you can cage them and then measure out the bees with a tin dipper, pour them down in front of the hives, and let them run in, the same as hiving a natural swarm.

I once caged eight virgin queens from one after-swarm, and they were so carelessly reared, as they were not good ones. In that case the bees hunt out the surplus queens for you. Sometimes they ball every queen, but not usually. It is an easy matter to tell whether every division you make has a queen by the number of bees. Bees in a clustering-box, or hived on empty frames without a queen, will very soon manifest uneasiness, and begin to run about, etc. If they have a queen they remain quiet. They will accept any strange queen—even virgins will be accepted, or a queeness, or a frame of brood containing eggs and unsealed larva.

Four years ago I had an observation hive in the wood-house, and the bees were passing out and in through a knot-hole. One queen was wanted. I flew through that knot-hole, so I went to work. I set up my clustering-box in the shade, went to a populous colony, carefully took out a frame of brood and adhering bees, shook the bees into the clustering-box, and as the bees were gathering nectar rapidly there was enough shaken on the bees and in the box to cause them to gorge themselves completely. I placed the comb back in the hive and closed it; I had not disturbed the old colony, either with smoke or drone-smoke. I went right along with the labor as usual. I went to four different colonies and took the bees from one comb, each in the same manner. I had my smoker on hand in case I needed it, but I did not have to use it, was careful not to get the queens from any hive I took a frame of brood from two different hives, inserting an empty frame in their places. It was in the middle of the day, so the old bees were nearly all in the field.

I placed the two combs with the adhering bees in a hive, and the cluster, all placed them in the wood-house, and now the boys have the satisfaction of seeing how the loaded bees throw themselves into that knot-hole instead of alighting on the outside and crawling in, as one would naturally suppose they would. The two boys take a great interest in the bees, so I am giving them lessons by actual demonstration.

One can make nuclei for queen-fertilizing or introducing at any time, in the above manner. If there is no sealed nectar to shake out with the bees, sprinkle them with diluted honey or melted sugar of the right consistency, so they will fill themselves. Be careful not to excite robbers at any time when the bees are at work. If there is danger, go through the operation just at night. I learned all those kinds of making swarms, nuclei, introducing queens, etc., in old box-hive times, from my old friend Wellhausen, years ago. It takes all the fight out of a bee when she is wounded with a stick, and then I am able to take the clustering-box and letting them stand awhile. They can then be hived and placed where we want them. They are to all intents like a natural swarm. One can take a pint of bees, mix them up with forty or fifty colonies and let them from a dozen colonies. Mix them all up in a clustering-box, and make a good swarm without perceptibly weakening the old colonies, and you get bees of all ages, the same as in nature. I was always taught that it makes them work with an extra vim.

I have occasionally received a queen from some friend, and have no colony that I wanted to introduce her to. So I have a swarm of bees from several different colonies. As soon as the bees manifest their queenlessness, hive them and let the queen run in with them, and the job is done.

In introducing a virgin, hive them on empty frames, and let them stand for a few hours, say over night, before giving them a frame of brood and honey. For I always like to set them up by themselves, as sometimes if they are not satisfied and will start queen-cells if given eggs and larvae at once. When we have a swarm, sometimes the weather turns bad for a few days, and then they need honey in the hive, or ought to have it.

I have moved my bees at times from one position to another by shaking and brushing them from their combs into a clustering-box, moved the hive to the new stand, and then let them stand awhile in the box, and they are moved.

**Italianizing Colonies of Black Bees.**

**By G. M. Doolittle.**

A CORRESPONDENT writes thus: "I am a beginner in bee-keeping and wish to know how I can best manage to Italianize ten or twenty of my black bees with the view of being least liable to go wrong. I am taking the American Bee Journal and am so captivated with it that I am anxious to know how others have met it away for reference. And so I should like to have you answer through this paper, and then I shall have your answer where it will not get lost."

Well, your last thought is one not often hinted at, and I must confess it is the black eaters, or what I shall hereafter meddled away for future reference. I have mine so filed, and there are few things in the back volumes of these papers, which are of practical value to the apiarist, but what I can turn to them, I can give you a very short time. If moving the beekeepers realized the value of the back numbers of the bee-paper they are taking, there would be more wisdom in our ranks than is often manifested, and less bee-papers found among the bundles the "paper-rags-buyer" carries off after visiting their homes.

But to the question: The Italianizing of your apiary depends upon whether you are desirous of doing all the work yourself, and thus learning all the little kinks of queen-rearing, or whether you simply wish to have all of your bees of the Italian variety as speedily, with no further attention being paid to the matter. If the latter, then I would advise buying untested queens of some reliable dealer; learn through him how to introduce them safely, and when introduced successfully you will have solved the matter.

If, on the other hand, you would like to know something of queen-rearing yourself, and no bee-keeper is fully a competent bee-keeper until he is perfectly familiar with the habits of the worker-bee, the queen, and their dependence on the queen-breeder, each one being good enough to stock an apiary with, and rear queens from one and drones from the other. Keep down all black drones by using only worker-combs and the comb of brood. These will make a piece three or four inches square in one comb, keeping that comb in a certain position in each hive, so that once every three weeks you can take these combs from the hive and shave the heads from the nearly mature drones.

Then if you paint that portion of the top-bar red, right over where the drone-comb is, you can at once tell where this comb is, should the frame get misplaced, from any reason, and if you have this comb near the top-bar to the frame and you keep the frame near to the side of the hive, you will rarely have to decapitate the drones more than twice a year, for it is natural for the bees to store honey at the top of the outside frames, and as soon as honey is stored in the comb, that ends the drones for that year. In this way you will have no black drones, and if your neighbors do not keep bees, and there are no colonies of black bees in the timber in any woods not nearer than four miles of you, you will have little difficulty in having the majority of your queen-mating bees black. I shall generally keep Italian, no matter whether you increase to 1,000 colonies, or allow them to remain at their present number.

But should there be black and hybrid drones in your neighborhood, do not become discouraged, for your young queens will breed true for the most part. The drones and the queens in this country are so hardy that the next year the most of your queens will mate with these. When, by selection after you have seen the progeny, you can soon have the apiary stocked with new drones.

By adopting this plan of rearing your own queens you
I BELIEVE, Mr. Bond, I promised yesterday to tell you about robbing in the apiary, when I could get a good opportunity. Well, I just noticed something about this drone-beheading business that has brought the mind to mind again—I mean those shavings from the drone-comb which I carelessly allowed to fall to the floor, and forgot to give the diron wood attention to, because I believe that fully seven out of every ten instances when robbing breaks out among bees, it is owing to some violation of an important rule—some thoughtless transgression of the law of vigilance, which in an apiary is always in force.

The sight of those drone-head shavings reminds me of an experience with the worst case of robbing I have ever been compelled to deal with. It was my first experience in api-surgery—the process of the sixth of Aug. I went from hive to hive in my search for drones and sliced all the drone-brood I could find. I found it harder work than I had anticipated, and it took more time than I had counted on; but it proved to be of inestimable importance in the course of that experience I failed to see—or foresee. I would better say.

Well, I was at the sixth hive in the course of my work when, suddenly I thought—but the fact is I have been too eagerly engaged in the work to notice anything else going on around me, and I was not aware that a large number of bees going over my head. For the first time since I had begun the job I looked up—and for about a minute by the clock I kept looking. It took that long for my startled mind to realize the little thing. 

"Robbing!!" I exclaimed aloud to myself, when I had finally taken in the most prominent signs and symptoms of the case.

Under ordinary circumstances I would have tried to figure out what was going on, or, on this sudden outbreak, before doing anything else—my mental machinery is built that way—but I had quick wit enough, for the moment, to see that this was no ordinary case of robbing. This was plainly evident to the naked eye, for the air was full of bees; I saw that a large number was going on in a darting—not merely flying, mind you, Mr. Bond—in every direction, and with a noise which I can't describe, but which sounded in my ears for weeks after.

"It is not usual for me to lose my head on the occasion of an apiary case, or, on one of this sudden outbreaks, before doing anything else—my mental machinery is built that way—but I had quick wit enough, for the moment, to see that this was no ordinary case of robbing. This was plainly evident to the naked eye, for the air was full of bees; I saw that a large number was going on in a darting—not merely flying, mind you, Mr. Bond—in every direction, and with a noise which I can't describe, but which sounded in my ears for weeks after.

"But that was not all, as I found when I came near the end of the row, for there stood the second of those hives open—I had forgotten to replace the cover. This alone is often enough to start robbing in an apiary, but here it was aggravated by a combination of circumstances. These circumstances, however, could not have combined to operate against me had I been thoroughly informed as to certain details. I did not know that the afternoon would not do as well as the forenoon for such a job of manipulation. Neither did I then know that it was not a good time for such a job when all the colonies are comparatively idle and are preparing for winter. And I tell you this, the fact that bees are never idle or quiet during the daytime unless there is no honey in the fields.

"And I tell you this, the fact that bees are never idle or quiet during the daytime unless there is no honey in the fields."

"The fact is—and I may as well own it, Mr. Bond—I had at that time a slight attack of a complaint known as 'big-head.' Nearly all bee-keepers have had it, more or less severely—usually during a fever caused by unexpected success. I imagined that I had already mastered the intricate science of bee-culture when, in truth, I had many of the most important things yet to learn. I had made the mistake, too, of supposing that because I had read two or three kinds of bee-books I had nothing more to learn. I have since learned that many essentials in the art of successful bee-keeping can not be found in bee-books—not because those who write bee-literature are not thoroughly informed, but because many things come to our knowledge by inference, and are not expressed in words.

"Well, I said to myself—I thought out loud during that exciting experience, Mr. Bond—"this is a sweetness! If only I knew what to do! But I can't think of a blessed thing I ever knew about robbing! And it's getting worse and worse all the time! The fracas is on all along the line—and getting worse at the other end, I declare!"

"At this moment I heard some one shouting my name, and on looking around I saw my dear little wife—any possibility of helping me to finish robbing the honey at the kitchen doorway, gesticulating, and shouting: ' Shut the hives, John! Shut the hives, quick!'

"I didn't at once understand what she meant by 'hives,' not being aware that more than one was open; I had enough reason to turn to me so that I could see the hive right before me and the cover by its side. I had been too completely dumbfounded to see that first important thing to be done toward controlling the robbers! I quickly put that to right, and, robbing them, I could not help seeing another all the way from the house. She pointed toward the end of the line of the six hives. I ran in that direction and slapped the cover on that hive in a jiffy. In the midst of excitement and having the robbing going on, I had left the hive without replacing the cover, and the robbers had discovered my mistake before I did.

"What did you do next?" queried Mr. Bond. We were walking toward the honey-house as I was talking; and, as I opened the door and asked him to walk in and take a seat, I answered:

The next thing I did was promptly to execute another suggestion my wife made to me, and partly executed herself when she came running toward the apiary with an armful of quilts and pieces of carpet, calling as she ran, 'Here, John! Take these and throw one over each of the hives most in danger, and call this the daytime work all the way around.' And then she wanted to know whether she hadn't better get her bee-veil and help me get out of the scrape! I tell you, Mr. Bond, it never pays to ignore our women-folks in this business. They remember things better than most of us men, and they nearly always know what to do in sudden and perplexing emergencies.

"Did that put a stop to the robbing?" Mr. Bond inquired, as though not having heard the last sentence.

"No, it did not. But it seemed to bother the robbers for awhile, as my wife suggested it would. But by this time I had recovered my wits, and was now ready for further development. I didn't dare to close, or even to contract very much, and I knew that my hives were safe. I had experienced a fine colony in that way the year before, and by the same process also ruined two supers full of nicely finished section-honey.

"Not knowing what I could do further to stop the robbing I got my sprinkling can and for an hour or more kept the hives where the bees were the most aggressive wet all the time. Soon after, night came on; and that put a stop to the business for that day.

"Before I went to bed that night I got out my bee-journals and looked them over for articles on 'robbing,' I found some good things on the subject, and stored them 'for keeps' in my memory. No doubt I might have arrived at the same conclusion if I hadn't first came to hand, but not having an acute case of robbing on my hands at the time I did not charge my memory with the subject-matter, and hence my forgettery took charge of it instead.

"Well, one of the articles on robbing advised the putting into a raw of water. I proceeded to see what kind of water had that was being robbed, and then keeping it wet by sprinkling water on it at frequent intervals. That struck me as a good idea and I determined to try it next day if robbing remained.

"Another of the articles said, 'Take the hive that is being robbed and carry it into your cellar, if you have one and it's handy, and leave it there for a few days.' I thought that was a capital scheme, too, and resolved to try it next day, if necessary.

"In another article I found the prescription highly recommended, to change the location of the bequeathed hive, reverse the entrance-front, and cover the hive with a
piece of carpet to disguise it. I am not now certain that this triple-advice was given by the same author, but I am sure that I used it next day in that combination, and with satisfactory results.

"The straw recipe I used next day on those of the hives that were not badly afflicted, and it worked splendidly. I liked it especially because it called for no lifting or carrying of the heavy hive. I have often tried that since, and always with the same success."

"But the cellar recipe took the cake, of course—that is, as far as effectiveness went. It suited me too, because I wanted to test all these methods, and because I had a cellar; and also because it happens to be handy for emergencies caused by bee-frecasies, as you probably remember, Mr. Bond.

[To be continued.]"

**The People of Rochester, N. Y., v. The Bees.**

On page 483 we published a statement from General Manager Secor concerning the lawsuit between the city of Rochester, N. Y., and Mr. W. R. Taunt, a bee-keeper residing there. The National Bee-Keeper's Association helped defend Mr. Taunt, and of course won as usual.

Mr. Secor has forwarded the following copy of the brief submitted by Attorney Frederick L. Dutcher, counsel for the defendant:

**POLICE COURT, CITY OF ROCHESTER, N. Y. v. THE PEOPLE, v. TAUNTON.**

**Memorandum for Defendant.**

The defendant was arrested upon a warrant based upon an ordinance passed by the Common Council of the City of Rochester on April last, which provides in substance that no bees shall be kept or maintained within the limits of the City of Rochester, without the permission in writing of the lot owners owning lots within one hundred feet of the hives within which any bees are desired to be kept or maintained.

At the trial, the defendant moved that the warrant be dismissed and the defendant discharged, upon the grounds:

First.—That the ordinance upon which the warrant is based and which defendant is accused of violating, is unconstitutional and void.

Secondly.—That the ordinance in question is not fair, impartial and reasonable, but is oppressive.

Thirdly.—That the ordinance in question is an unlawful attempt on the part of the Common Council to delegate its power to private individuals.

Upon this motion, the defendant will not discuss the question whether the Common Council has power to prohibit the keeping of bees, as that question does not arise under this ordinance.

In the first place, the question whether the ordinance is unconstitutional, or whether it violates some other principle of law is a question of law for the Court, and must be decided irrespective of the facts in any particular case.

In People ex rel. Kraus v. Durston, 110 N. Y., at page 578, the Court says: "If it can not be made to appear that a law is in conflict with the Constitution, by argument deduced from the language of the law itself, or by showing in accordance to which a court can take judicial notice, then the act must stand. The testimony of expert or other witnesses is not admissible to show that in carrying out a law enacted by the legislature, some provision of the constitution may possibly be violated."

In the Matter of Elevated Roadway, 70 N. Y., at page 287, the Court holds that a Court can not take proof of facts for the purpose of showing a statute valid and regular upon its face to be unconstitutional.

So that the question whether the ordinance is fair, impartial and reasonable must be determined from the ordinance itself.

In Beach v. Public Corporations, Sec. 512, the learned author says: "It is a well-settled principle that a municipal by-law or ordinance must be reasonable. The Courts will decline to enforce it, it will be declared void as a matter of law."

And again at Section 514, the same author says: "It is, of course, a question of law and not of fact for the Court, and not for the jury, whether any specific ordinance is so unreasonable as to be void."

**First.**

The ordinance is passed under the so-called police powers of the City, but the police powers of the City are not above the Constitution and are subject to the control of the Courts.

In Re Jacobs, 38 N. Y. 98, at page 110, the Court says: "These citations are sufficient to show that the police power is not without limitations, and that in regard to the legislature must respect the great fundamental rights guarantied by the Constitution. If there were otherwise, the power of the legislature would be practically without limitation. In the assumed exercise of the police power in the interest of the health, the welfare or the safety of the public, every right of the citizen might be invaded and every constitutional barrier swept away. Under the mere guise of police regulations, personal rights and private property can not be arbitrarily invaded, and the violation of any of the fundamental rights of the legislature is not final or conclusive in such matters not that the legislature may. in the title to the act or in its body, declare that it is intended for the improvement of the public health. Such a declaration does not conclude the courts, and they must yet determine the fact declared and enforce the supreme law."

**Second.**

The ordinance is unconstitutional for two reasons. First, it is an attempt to take property without due process of law; and, secondly, the ordinance denies the equal protection of the law, as guaranteed by the fourteenth amendment to the United States Constitution.

In Steward v. Palmer, 74 N. Y. 183, due process of law is defined as follows: "Due process of law is not confined to judicial proceedings, but extends to every case which may deprive a citizen of life, liberty, or property, whether the proceeding be judicial, administrative, or executive in its nature."

In Re Jacobs, supra, the facts were that the legislature passed a statute prohibiting the making of cigars in tenement houses in New York and Brooklyn. The Court of Appeals set the statute aside as unconstitutional upon the ground that it was depriving persons of property without due process of law. The Court says, at page 104: "What does this act attempt to do? In form, it makes it a crime for a cigar-maker in New York and Brooklyn, the only cities in the State having a population exceeding 500,000, to carry on a perfectly lawful trade in his own home. Whether he owns the tenement house or has hired a room therein for the purpose of prosecuting his trade, he can not manufacture therein his own tobacco into cigars for his own use or for sale, and he will become a criminal for doing that which is perfectly lawful outside of the two cities named—everywhere else, so far as we are able to learn, in the whole world."

In the case at bar, the ordinance makes it lawful to keep bees in one part of the city, provided certain consents can be given; but to keep the bees in another part of the city would be unlawful if the consents were not obtained.

The Court further says in the case cited, at page 105: "The constitutional guaranty that no person shall be deprived of his property without due process of law, may be violated without the physical taking of property for public or private use. Property may be destroyed, or its value may be annulled; it is owned and kept for some useful purpose, and it has no value unless it can be used. Its capability for enjoyment and adaptability to some use are essential characteristics and attributes without which property can not be conceived; and, hence, any law which destroys it or its value, or takes away any of its essential attributes, deprives the owner of his property."

In Butcher's Union Co. v. Crescent City Co., 111 U. S. 746, Judge Field says: "The common businesses and callings of life, the ordinary trades and pursuits, which are innocent in themselves, and have been followed in all communities from time immemorial, must, therefore, be free in this country to all alike upon the same terms. The right to pursue them without let or hindrance, except that which is applied to all persons of the same age, sex and condition, is a distinguishing privilege of citizens of the United States, and an essential element of that freedom which they claim as their birthright."

In the same case, Judge Bradley says: "I hold that the liberty of pursuit, the right to follow any of the ordinary callings of life, is one of the privileges of a citizen of the United States, of which he can not be deprived without invading his right to liberty within the meaning of the constitution."

In the case at bar, the ordinance attempts to deprive a person of his property and prevent its use at the mere will of a private individual. The duly constituted authorities of the City do not act in the matter at all, but turn over their powers to private citizens who are taking the liberty at their own sweet will to destroy the property
belonging to another. Can there be any question that this is taking property without due process of law?

Secondly.—The ordinance is unconstitutional because it denies the equal protection of the law, as guaranteed by the fourteenth amendment of the United States Constitution. Upon this point, we will call the attention of the Court to the case of *Vick v. W. Hopkins*, 111 U. S. 356. In this case, the Board of Supervisors of the City and County of San Francisco passed an ordinance which provided that it should be unlawful for any person to establish, maintain or carry on a laundry within the corporate limits of the City of San Francisco, without having obtained the consent of the Board of Supervisors, except in the case of buildings constructed of brick or stone. It will be noticed that in the San Francisco ordinance the consent of officials was required, while in the ordinance which we are discussing, only the consent of private individuals is required. An ordinance which requires the consent of officials is certainly more reasonable and proper than one which requires the consent of individuals. Public officials are bound not only by the dictates of their consciences, but also by the weight of their judicial and executive responsibility to the people for their actions; while private individuals can act at their own sweet will. In speaking of this ordinance passed by the Board of Supervisors of San Francisco, the Supreme Court of the United States says, during the progress of its opinion: ‘We are not able to concur in that interpretation of the power conferred upon the supervisors. There is no machinery in the ordinances which points to such a regulation of the business of keeping and conducting laundries as the supervisors are especially empowered to do. A discretion is to be exercised upon a consideration of the circumstances of each case, but a naked and arbitrary power to give or withhold consent, not only as to places, but as to persons. The power given to them is not confided to their discretion in the legal sense of that term, but is granted to their mere will. It is purely arbitrary and acknowledges neither guidance nor restraint.’ And, again: ‘It does not prescribe a rule and conditions, for the regulation of the use of property for laundry purposes, to which all similarly situated may conform. It allows without restriction the use for such purposes of buildings of brick or stone; but as to wooden buildings constituting nearly all those in previous use, it divides the owners or occupiers into two classes, not having respect to their personal character and qualifications for the business, nor the situation and nature and adaptation of the buildings themselves, but merely by an arbitrary line, on one side of which the persons who are permitted to pursue their industry by the mere will and consent of the supervisors, and on the other those from whom that consent is withheld, at their mere will and pleasure. And both classes are alike only in this: that they are tenants at will, under the supervisors, of their means of Hiving.’ And, again: ‘For the very idea that one man may be compelled to hold his life, or the means of living, or any material right essential to the enjoyment of life, at the mere will of another, seems to be intolerable in any country which vests in a public authority the right and power of making rules as to the use of property, to which all similarly situated may conform. It allows without restriction the use for such purposes of buildings of brick or stone; but as to wooden buildings constituting nearly all those in previous use, it divides the owners or occupiers into two classes, not having respect to their personal character and qualifications for the business, nor the situation and nature and adaptation of the buildings themselves, but merely by an arbitrary line, on one side of which the persons who are permitted to pursue their industry by the mere will and consent of the supervisors, and on the other those from whom that consent is withheld, at their mere will and pleasure. And both classes are alike only in this: that they are tenants at will, under the supervisors, of their means of Hiving.’ And, again: ‘The same principle has been more freely extended to the quasi-legislative acts of inferior municipal bodies in respect to which it is an ancient jurisdiction of judicial tribunals to pronounce upon the reasonableness and consequent validity of their by-laws.’ And, again: ‘Though the law itself be fair on its face and impartial in appearance, yet, if it is applied and administered by public authority with an evil eye and an unequal hand, so as practically to make unjust and illegal discriminations between persons in similar circumstances, material to their rights, the denial of equal justice is still within the prohibition of the Constitution.’ And, again: ‘The discrimination is therefore illegal, and the public administration which enforces it is a denial of the equal protection of the laws and a violation of the fourteenth amendment of the Constitution. The imprisonment of the petitioners is therefore illegal, and they must be discharged.’

No authority is needed except the case cited. A reading of the complete opinion of the Supreme Court of the United States will show that that high judicial authority condemned in the most severe terms ordinances like the one which we are discussing, as being not only not reasonable, but a denial of the equal protection of the law.

**Third.**

The ordinance is void, because it is not fair, impartial and reasonable, but is oppressive.

In *Beach v. Public Corporations*, Sec. 90, the author says: ‘A city, although fully authorized to enact ordinances, can not pass unreasonable ones. The ordinance of a city must be reasonable. It must not be oppressive; it must not be partial or unfair.’ The same author says, at Section 512: ‘It is a well-settled principle that a municipal law or ordinance must be reasonable.’

In *Dillon v. Municipal Corporations*, Sec. 319, the author says: ‘In this country, the courts have often affirmed that general incorporated power of municipal corporations to make ordinances, but have always declared that ordinances passed in virtue of the implied power, must be reasonable and consonant with the general powers and purposes of the corporation, and not inconsistent with the laws or policy of the state.’

In the case of *Vick v. W. Hopkins*, supra, also held that municipal corporations must be reasonable.

Can it be said that the ordinance which we are discussing is reasonable?

It does not provide that citizens living within one hundred feet must give their permission to keep bees, but that the owners of lots wherever they may live must give such permission. These owners might live in New York, Buffalo, or in Europe, and have no personal interest in the matter, and yet their permission is required. Again, under this ordinance, permission might be obtained, and then, immediately afterwards, the lots within one hundred feet of the place where bees are to be kept might be sold, and permission would have to be obtained of the new owners.

Under this ordinance, a person who owns a lot in the outskirts of the City, a mile from any dwelling, might not be permitted to keep bees, while a person living in a thickly populated district can keep bees, if he get the requisite permission. In other words, under this ordinance, the owner of a lot in the center of a city or adjoining a municipal park may be permitted to keep bees, while a person owning a lot in the outskirts of the City would not be permitted to keep bees. In fact many illustrations might be given, and will readily suggest themselves to the mind of the Court, of the purely arbitrary character of this ordinance and the unjust manner in which it may operate.

The private citizen, from mere caprice or ill-temper or bad feeling against the bee-owner may deprive him of the use of his property.

In fact, the right depends wholly upon the personal inclinations and caprice of adjoining lot owners.

**FOURTH.**

The ordinance in question is an unlawful attempt to delegate the powers conferred by law upon the Common Council to private individuals.

Article Two, Section 12, of the City Charter, provides that the Common Council ‘has authority to enact ordinances not inconsistent with the Laws of the State, for the government of the City and the management of its business, for the preservation of good order, peace and good health, for the safety and welfare of its inhabitants and the protection and security of their property.’

This statute plainly contemplates that the discretion as to whether a certain thing is or is not a nuisance must be vested in the Common Council; but in the ordinance in question, bees are a nuisance, or that they should only be kept in certain prescribed portions of the City, but the Common Council has turned its powers and its discretions entirely over to private individuals. That the Common Council has not passed upon the question as to whether or not bees shall be kept, is illustrated by the fact that with the requisite permission of adjoining lot owners, bees can be kept in every lot in the City of Rochester. There is an ordinance in force which provides against intoxication in public places; but suppose an ordinance should be passed which would provide that a person might be intoxicated in a public place, provided he could get the written permission of every person owning property within a certain distance of the place where he desired to get drunk—could such an ordinance be supported in the Courts? And yet, such an ordinance would be precisely like the one in question.

In *Birdwell v. Clark*, 73 N. Y., 473, the Court holds that public powers of trusts devolved by law or charter upon the Common Council or governing body of a municipal corporation, to be exercised by or when and in such manner as it shall judge best, can not be delegated by such body to others.

The ordinance is not a determination by the Common Council that the preservation of good order, peace and health, the safety and welfare of the inhabitants of the city, and the protection and security of their property demands that bees shall not be kept; but the ordinance leaves such questions entirely to the determination of private individuals. Under the ordinance, there is absolutely no restriction to the keeping of bees in any part of the city, providing the bee-owner can obtain the consent of his adjacent lot owners. There can be no ques-
Caging the Queen During the Honey Season.

1. If you wish to cage a queen in the honey season, do you cage her in a fine wire cage, or in a cage made of Queen-excluding zinc?
2. If you had a queen that you could not use at the time, if you put her in a wire cage, and then in a hive, would the bees feed her? If so, what kind of wire should be used?
3. If you had a young swarm, and only wanted what honey you could get that season, would you cage the queen? If so, in what kind of wire?

Increase from Poor Honey-Gatherers.

I read on page 451 about a colony that gave twice as much surplus honey as the average does; and if an increase was made by swarming, it would be by the poorest surplus gatherers. Do you think that a good colony could not come from the poorer surplus gatherers? I do, for I bought a colony of bees where two small swarms clustered together, which were hived in an eight-frame hive. The colony got a good start last fall, but this spring it was weak; I think, because their queen was old. My bees did well this summer (for I think they have 50 pounds of extracted white clover honey), considering where I have kept them.

When to Buy Bees in Box-Hives, Etc.

1. If I bought bees in box-hives (the old kind), could I buy early next spring, and transfer to dovetailed hives before swarming-time?
2. What month in the spring would you advise buying?
3. How much sealed honey should be in eight frames to winter one colony? Give about the depth, as I am no judge of pounds in frames, as I am a beginner.

Hiving Swarms.

1. I noticed in answer to Ben Avon, in Gleanings in Bee-Culture, page 239, about hiving bees on empty combs, he puts four frames in the hive and then fills it with dummy's. What are dummy's?
2. Do you put on the hives of prime swarms surplus fixtures as soon as they are hived, with a honey-board between the brood and surplus?
The Afterthought.

The "Old Reliable" seen through New and Unreliable Glasses.

By E. E. HASTY, Sta. B Rural, Toledo, O.

CO-OPERATION IN COLORADO.

W. E. Porter's account of co-operation in Colorado, on page 437, seems to show considerable success—a sort of boy-woodchuck success—and had to succeed, their local prices being cut down so low, and likely to go lower. Their being driven by their distance from market to act together in selling may eventually have a favorable effect on honey-selling anywhere. The boy who does not have to catch woodchuck may also go in to catch one.

WIRE-CLOTH OVER SMOKER-WALE.

So to keep that hounding "other fellow" from half spoil-
ing your smoker's valve with his bedaubed finger-tips—so simple—just a bit of wire-cloth put over. I'd go to work and thank Harry Howe for that, no one ever uses my smoker but myself. Page 444.

BEARS AND TURTLE'S EGGS.

We sometimes envy those who have the very best ranges of the world without thinking of the drawbacks. Where the ocean occasionally blows in almost all Baltic, and bears are pretty and come in, and both contingencies must be provided against—well, unless a fellow was pretty enterprising he might wish himself somewhere else. Stands seven feet high and bear-fence of barbed wire—say, dear Boss, ask him for a sample of that.

From Mr. Gifford's saying that sea-turtle's eggs are about as large as hen's eggs but not as good, I judge they use them— the better article being scarce in howling wildnesses. In a swamp near Fort Wayne, Ind., there used to be enormous turtles whose correspondingly big eggs provoked one to see if they could not be eaten. I have eaten them, but only a pretty hungry man would vote them worth eating. Page 444.

NATURAL INCREASE BY NATURAL SWARMING.

Dr. Miller touches a very sore spot, on page 445. Natural increase by natural swarming has many things in its favor. Perhaps the most important thing (most important if true) is, that the man who undertakes to improve bees, improves them the other way—disimproves them—and nature's proceedings are of larger scope than that. But we have to pause before the fact that the best colonies seldom swarm, and therefore we do not get increase from them but from poorer ones.

"DEAR BOSS" OR "DEAR BEESWAX."

And so instead of saying "Dear Boss," shall I say "Dear Beeswax?" Page 445-450.

The Crops of Wax-Scales.

If it takes 1,474,560 wax-scales to the pound, and the bee should increase a crop, the number of crops is 2,457,760. Comrundrum: How many crops will one bee produce as the result of a flow of honey lasting say seven days? I was going to say about three. But that would call for 8,192 bees. What's the matter? At least three things may be the matter. Possibly the secretions been add to the scale, and not been to reach up into finished wax largely increase the weight. It perhaps seldom happens that so much as a pound of wax is made during one run of honey. And perhaps my three crops from each bee should indicate in how rapid wax production crops of scales are raised? Possibly it may be already in print somewhere.

Let's begin again at the other end of the puzzle. A five-pound swarm (22,000 bees) need, in addition to the start their keepers gave till, a period of time to fill their chambers. If they really need 245,760 sets of scales, and nearly but not quite all the bees secret, that is twelve crops for each bee. So it looks as if when once begun the scale harvests came onerous than once a day. Page 446.

Evils of In-Breeding.

Apart the Simpson article on in-breeding, I am glad to see in-breeding opposed. Deededly harmful and "just awfully" handy. Often the ambitious breeder seems to have only the choice of breeding close, or giving up the thing he is working at. It is in us all to minimize too strongly evils of scents evens which we find very convenient indeed. The wise man should deplore necessary evils, not warp his judgment into praising them.

I can hardly agree that long tongues are merely a symptom of the long pole and the particular; it is not a symptom of the gale which swells them down. Pages 453-5.

The Home Circle.

Conducted by Prof. R. J. Cook, Claremont, Calif.

Kindness to Animals.

I have already, perhaps more than once, referred to thoughtful care and kindness in the treatment of our animal friends. I love the "Beautitudes," be they not fast locked in memory, but also enshrined in his heart. It is suggestive of that of the nine Beatitudes, the fifth, or pivotal one (and the one next to the "Blessed are the pure in heart; for they shall see God." Often I have heard a superintendent of public instruction, of Michigan, say that he would give a teacher a certificate who could not repeat the words to "America." Such a one would be incompetent in the line of patriotic instincts.

One is certainly better equipped for all life's struggle who has the "Beautitudes," not only fast locked in memory, but also enshrined in his heart. It is suggestive of that of the nine Beatitudes, the fifth, or pivotal one (and the one next to the "Blessed are the pure in heart; for they shall see God." Often I have heard a superintendent of public instruction, of Michigan, say that he would give a teacher a certificate who could not repeat the words to "America." Such a one would be incompetent in the line of patriotic instincts. Then, too, we ought to give earnest heed to our own reputation. The same blessed Book says: "Avoid the appearance of evil." How sadly must everyone be judged—whether we drive a lean, hungry, decrepit old horse. I can but think that such a one may well pray, "Lord be merciful unto me a sinner." Cruelty to a man, who can speak and defend his right, is indefensible; to a child unable to defend himself, it is despicable. "Lord be merciful unto him who neglects or mistreats his horse or cow? These faithful friends can neither defend themselves nor voice their ills. Shakespeare might well have said of such a one, as he did the miser, "I'd rather be a dog and bay the moon, than such a man." So much if we could all rise on that one, our pleasure, our profit, our reputation, were being weighed in the balance, we would clothe up the uncanny old ribs of the faithful old horse, and would feel more like men, in the assurance that we were not treading under foot that best precept—the golden rule.

All this is written because of an object lesson which our canyon experience brought to us. Each of two men—both splendid men—had their horses with them. These men were both of our party. They are men of high Christian character, and possess, deservedly, the love and sincere respect and esteem of all their neighbors and acquaintances. Yet in one respect there was a contrast. The horses of one were fat, fine and beautiful. Their round, plump bodies, and fine sleek, shining coats, showed that they were subjects of thought—
ful care and attention. There seemed to be a happy understanding between horses and master. Feeding and watering were always prompt, regular and generous. When out with the saddle, in climbing the steep, rugged mountain trails, a halt and rest was often necessary. If these were at all prolonged, the clinch was loosened. No wonder those horses were ready for the hardest climb, and stoutest pull, and it was a pleasure to note the pride which all in the family seemed to feel in these horses. I believe the horses felt the appreciation. It is a united family, and the horses may be counted in.

The other man's horse had ribs—great, big ribs—twenty-eight of them all standing out in boldest relief. He also had a sore shoulder. The feeding was not prompt, was not regular, was, I dare say, at times omitted entirely. This horse did not seem in love with life. Were I his master I should fear he did not love me. I am sure I should take no pride in driving him. And I hope I should have disturbing dreams, in which the 5th "Beatitude" and the Golden Rule would play a conspicuous part. I doubt if this horse was uncinced in the rest times, as he bore his owner or other up the steep mountain sides. "Old Tom" refused to draw his load as he came to the steepest, hardest climb. He seemed to say, "I can't do it; it is too hard."

I wish again to repeat the lines of Eliza Cook:

"Oh, if to us one precious thing
Not theirs—a soul—is given:
Kindness to them will be a thing
To bear it up to heaven."

MUSIC IN THE HOME.

I wonder if we all appreciate the added charm that music gives to the home. Charles Darwin made the lamentable confession that, whereas he, as a boy and young man, was very fond of music, art, and poetry, he gave his life so exclusively and so energetically to scientific research that he lost his love and taste for the other things. He did such grand work in science that we may the less regret the atrophy of the other qualities. He regretted this withering-up process, and said that were he to live his life over, he would give time to cultivate these other desirable faculties of his being. Does not the parable of the talent and the napkin urge us to round out our being and lives by cultivating all our faculties? I have had a somewhat similar experience to that of Darwin, and I also regret it. In my early life I was not only very fond of music, as I am still, but I quickly learned music. Hearing a piece sung once or twice, would make me able to sing it correctly. My daughter now sings, and some of her pieces delight me beyond expression. Yet, though I have heard them sung a score of times, I cannot sing them. Were I to live life again, I should keep this music in my soul, rich and full. I have missed much.

Again, I know of several who seemed to have little taste or aptitude in music, who, by study, have become fine musicians. Music is so rich a gift and so priceless an adornment in the home that its cultivation may never wisely be neglected. It refines performer and listener. It gives the healthiest and best recreation, the keenest and most wholesome entertainment. If anything will fasten the love of children in the home, and stay their footsteps from wandering away, it is music.

I wish all our home circles might be the center of fine and oft-recurring concerts, that all the members might be the more knit into one bond of love and good fellowship.
ADVERTISEMEN

To Our Shippers:

We were obliged to notify you a few weeks ago that one Joseph M. McCaul had leased our old quarters at Nos. 120-122 West Broadway, New York City, and had there started up business under the name "Hildreth, McCaul Co." and had distributed a multitude of circulars so worded as to create the impression that his business was a successor to or a branch of the business of Hildreth & Segelken.

For the protection of our shippers and ourselves, we at once instructed our attorney to commence action to enjoin the said McCaul from using the name HILDRETH in any manner whatsoever in connection with his business. On the 10th day of July, 1901, Hon. David McAdam, Justice of the Supreme Court of the State of New York, after a full argument upon the merits, issued a peremptory injunction, of which the following is an extract:

"And it appearing that the plaintiffs have for a long time been and now are carrying on business under the style of 'Hildreth & Segelken,' and that the defendant has recently opened a business at 120-122 West Broadway, in the Borough of Manhattan, City of New York, and is carrying on the same under the style of 'Hildreth, McCaul Co.,' and that such act is in violation of the plaintiffs' rights, and that the commission or continuance thereof, during the pendency of this action will produce irreparable injury to the plaintiffs; it is

ORDERED that the defendant (Joseph M. McCaul) and each of his agents, servants and employees and all other persons acting under his authority and direction be, and he and they are hereby restrained and enjoined from showing, displaying or otherwise using during the pendency of this action in or upon any papers, devices, sign or signs, or otherwise, in the business conducted by the defendant at No. 120-122 West Broadway, in the Borough of Manhattan, City of New York, or elsewhere the name of 'Hildreth' separately or conjunctively with any other name, designation or description."

Outside of our desire in our own interests to protect the name which we have built by years of satisfactory dealings with our customers, we hastened to procure this injunction as soon as possible, to prevent our shippers from being misled into sending their goods to one who would make an attempt to gain their trade by such a trick and device.

With thanks for the many expressions of good-will we have received from our shippers concerning this attempt to trade under our name, we are,

Sincerely yours,

HILDRETH & SEGELKEN,

265-267 Greenwich Street, NEW YORK, N. Y.

An American M.

Bee's Did Fairly Well.
The bees did fairly well here the forepart of the season on white clover, but it all dried up. We did not have any rain for three weeks. It happened I think we will have some back honey next year.

Monroe Co., Wis., July 25.

Drott and Little Honey.

There is but little honey in southern Iowa, and in Missouri I think it is still scarcer. I had about 1,000 pounds from colonies enough to have stored 5,000 in a good season. The gathering came to a sudden stop in the early days of July. I have had swarms some seasons as late as July 15. I had the broad frames of a Jumbo hive. Our July was the hottest and driest anyone remembers. No rain up to June 27. We have had some rain now. Corn will make less than half a crop. Potatoes and garden vegetables are not over. I have no honey this June. I am going to have some of the swarms now. I am hoping for a fall flow. If it does not come I have the choice of heavy feeding or starving bees.

E. R. TULLI.

Bee's Have Done Well.

My bees have done well this season, giving me a nice surplus of white honey, with the fall flow now commencing and prospects good.

E. B. TURELL.

Geneseo Co., Iowa, Aug. 9.

Bee Selecting a Home Before Swarming.

Rip Van Winkle says, on page 492, he does not think that bee select their future home, for certain reasons. And I know they do, under certain conditions. Still, as a rule, they do not.

Years ago I kept bees in Canada, in box hives. I had a colony that swarmed the first year, and among the bees that were clustered on the outside of the hive would go into the hive, fill themselves with honey, and pack it closely in and under the hive. I had a colony for swarming, and it set in to rain, and continued more or less cold, windy and wet for eight days. Then the bees swarmed, and went directly to their selected (or where their selected) tree stood. The sun came out for half an hour, and the bees went to that tree, swarmed and selected the tree. I had two men shopping, and they reported that bee full of honey, an swarm of bees. So we cut the tree down, and not a bee was there. It was raining lightly when we cut that tree, but once the bees all go at once, almost like emptying a bucket of water by turning it upside down. It never rains without a storm. We went straight for their selected tree. They hazed about for quite awhile, and finally clas-
tered, and we bled them and took them home.

Another similar case was in Iowa. A swarm was prepared to come out, but the weather turned bad for eight days, and when they finally left in July, they kept on a surry. I ran about a mile into the woods and came up to them as they were going into their tree. They were heard by their loud hum or roaring at a distance of ten rods. I ran in the right direction, and then would stop and listen. The last run I made passed them about six rods. Of course I cut down the tree at once, and took them home.

A man at Linton reported a swarm of bees in his pile of fruit-boxes; that was four years ago, and he wanted me to get them, so I went and took them there. But they came the following day. The man saw the swarm there, and supposed they had already taken possession. Thus they were probably scouts from a clustered swarm. I do not believe one swarm out of a thousand looks up its locality before clustering in this climate, as there is no necessity for it on account of the weather being always favorable.

There was no rain on the 19th of last April. They had been clustered for two days, had dashed the limb of the tree where they clustered all white with wax. I now have eight colonies of them, Dr. E. Gallup, Orange Co., Calif., July 15.

No Rain for Over Two Months.

There has been no rain in this vicinity in over two months, and corn is ruined; there are dry and become dead, so no honey would be gotten for winter. Water in wells and cisterns is giving out, and fruit is scarce. Honey will bring a good price, or should do so.

E. T. Flanagan.
St. Clair Co., Ill., August 7.

The "Jouneer"—by the Original
Jouneer.

Upon receipt of the American Bee Journal for July 5, I was a little surprised,—gratified more than a little, and actually felt better over my condition. Mr. M. J. Y. reported that he uses in his enthusiastic praise of my quick method of getting bees out of an extracting-supplier. He has several of them, and he has never lost any. The "Jouneer," in my practice, was devised for the purpose of quickly riddling a shallow Heddon super of bees, and the crude affair filling out three or four boxes. He has about three years ago, worked so well that I made a neat, substantial device, constructed with a cloth bag upon the top of the super, the bees are caught, reducing the killing of bees to a minimum, and getting them in such shape as to dump them on the top of the extracting-supplier instead of scattering them all over the ground.

It seems to me that three years after description is a long time to be for beekeepers to catch on to such a very short cut.

But when I consider that my own enthusiasm over my device was somewhat curbed by the sort of half-way ridicule with which my statement in relation to its benefits were received by some of my brother beekeepers here, I do not wonder, then, that only one man, so far as heard from, has taken kindly to it.

Perhaps the name "jouneer" has something about it that excites the ridicule, or that the Rambler used it had some adverse effect. Any way, the bees are shaken out, they are given a sudden, quick jar, or for a more euphonious word, "jouneer, and the device, a "jouneer." I have used the principle more or less for the past few years, and have kept mum about it for fear of ridicule.

When I left my own apiary in the southern end of this State, in charge of other parties, I had a long string of bees turning over my jouneer to them. As the parties were very sensible young men, I ran the risk, first showing them by practical demonstration the use of the device and its effects. After the extracting season had well advanced, I received a letter from the parties, saying, "We are falling in love with your shallow super and the jouneer." That settles it as far as the Shaffner lives are concerned; they know a

Superior Red Clover Queen

For sending us One New Subscriber and 25 cents ($1.25 in all).

We arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us this season. His bees average quite a good deal the longest tongues of any yet measured. The queen bees are distant from Italy, having imported her herself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

good thing after they have used it, and have

gotten rid of the laborious process of brushing
bees from the combs.

It is just possible that others besides Mr.
Davenport have used the plan, or have tried
to use it; perhaps a comb or two has broken
down in the first attempt. I think they are
more likely to break in a frame deeper than
the Heddon—that may have condemned the
plan in their estimation: but what if a comb
does break now and then, has there not been
an immense saving of time? And the more
the plan is used, the more skill acquired and
less combs broken.

I think Mr. Davenport is entitled to some
credit for the use of the principle, for I have
used it only on similar supers, while he goes
further and uses it on deeper frames. Any
way, I hope the plan will be useful to other
kepers.

Fresno Co., Calif.

60 Pounds Red Clover Per Colony.

G. M. Doolittle says in the Progressive
Beekeeper:

For the past 30 years red clover has failed
to blossom in central New York, owing to an
almost infiniteesimal insect which works in
great numbers in each head, just before the
blossom would appear. This causes the head
to harden and no blossom to open. But this
year owing to our continued rainy weather,
or some other cause, we had fields red with
clover blossom again, and when the hot weather
came on the bees began to roll in the honey at
a rate never known before, outside of a
good basswood yield, and for three or four
days it was equal to any basswood yield. It
could leave combs of honey out in the bee-
yard all day long and not a bee look at the
honey, though several might be seen collect-
ing propolis off the ends of the frames where
they come in contact with the hive. And as
brood-rearing was pretty good, 37 days before
this clover yield began, from 50 to 70 pounds
section honey is the result from colonies
which had not been robbed of bees and brood
to make nuclei with, to rear queens for the
trade.

If I hear some one asking about the
"long-tongues," Well. I have not had time to
have any measurements taken, as I have
been too rushed this season hardly to sleep
nights, but if any have long tongues all must,
as I see little difference in the working of any
colonies, that is, against the crater-plate. This
and from the first crop of red
clover. The most claimed by those having
reared queens is, that they are on
the second crop, that is, of course combs, and then
the blossoms of the first crop.

The Root German Steam Wax-Press.

This is now put upon the market by the A.
I. Root Co. Copying after the Germans, who
have been ahead of us in this matter, a very
superior wax-press has been completed, which
is perhaps an improvement upon any
in Germany. It is of large size, holding
more than a bushel of combs at a time. Its
manipulation is given in Gleanings in Bee-Culture as
follows:

To use, the cane is placed on a common
stand, having with about three inches
to
water. The wire-cloth basket is filled with
old comb, slumgum, or any wax refuse. The
water is then added until the pressure-
plate is completely filled. The wire-cloth is
then set down on top of the can, and the
water is allowed to boil. The steam gen-
erated passes all through the mass, and when
the wax in the basket settles down, more re-
fuse is put in. After all the free wax is
steamed out, the screw and plunger-plate are
turned down. One person grasps the two
handles of the can, and another one turns the
screw down until a slight resistance is exerted. It
is then left for a little while when another
all along to keep up brood-rearing, and some-
times we get some surplus), we again go
through all, and, taking off the top (or third)
story, we go through the brood-chambers,
pulling all combs with honey in the top, or

Catnip Seed Free!

We have a small quantity of Catnip Seed which we wish to offer our
readers. Some consider catnip one of the
greatest of honey-yielders. We will
mail to one of our regular subscribers
one ounce of the seed for sending us
one new subscriber to the American
Bee Journal for a year with $1.00; or
will mail to any one an ounce of the
seed and the American Bee Journal one
year—both for $1.30; or will mail an
ounce of the seed alone for 50 cents. As
our stock of this seed is very small, better
order soon.

QUEENS! QUEENS!

From honey-gathering stock. Tested, $1.00; un-
tested, 75 cents. "SHEEP NOOK A.P.

the third super, and all the empty combs in
the two chambers of the brood-nest, arrang- ing
the combs so as to spread the brood, and
to push brood-rearing, as we want a great
force of bees just at the beginning of the
main flow, which will be about the first
of August.

The other super, containing the combs of
honey, is now set on top. This operation will
generally commence early in the month of
March, sometimes sooner or later, depend- ing on the earliness or lateness of the
season; and at this time, if the colonies
are overpopulous, combs of hatching
brood are taken from them and used either
to strengthen the weaker colonies or for
stocking nuclei. If some of the colonies have
already started queen-cells they are destroyed or ut-
erwise treated, and the white hive has
said something about swarming; but with
such a large brood-chamber, and providing
plenty of stores in the queen, there will be
very little if any swarming; but I gave the
foregoing for the "exceptions."

Now comes the time of our main flow, which is
just beginning; and we have above, in the
favorable we shall have strong colonies with
a large force of bees; and, besides having had
plenty of honey-flour, is put in this win-
time, we will have some surplus stored in the
shallow extracting-supers above.

When you start to get on the comb-
Baker reversible bottom-board, we proceed as
follows:
Prer set one of the section-supers down,
and on this set the upper (third) case of
the hive, without removing the cover.
Then move the frames with the double,
bottoms and all, to one side of the stand, and
in its place put the extra Danzebnaker-bottom
—the deep frames, without the cover, on the
upper one of the two brood-chamber cases,
and on this the lower one, thus cutting the
broom, will carry the honey up into the
upper frames in the center of the brood-nest for
the bees to remove, while the upper frames
are employed for the brood.

The two other supers, the section super
with the extracted-honey super above it, are
now set on top of the brood-chamber. Here
are two features of this system that you will
please; namely, in having bees first used to
storing in shallow extracting-supers; and
when we come to store the double, full and
clean boxes of honey can be produced between
such a super than where the cover is directly over
the frames, as it is in the shallow storage
-supers during the time before the main
flow, as we have honey coming in nearly all the
time, and it is really a little more necessary
for brood-rearing, it is stored in these
supers, leaving plenty of room for the
queen, while otherwise it would have to go to
waste or the bees would store it in the
brood-chamber, thereby crowding out the
queen.

With a set of these frames above, too, if a
colony has more honey in the brood-chamber
than is needed, the bees, when providing
room for the queen up into these frames,
also bringing the brood up to the
top of the frames.

More Bee-Keepers' Paradises....

E. R. Root has just returned from a 6,000-mile trip through some of the best bee-locations in the world, and has already begun his series of write-ups, accompanied with fine photos, in Gleanings in Bee-Culture. The following editorial appears Aug. 1, and will give something of an idea of what he will describe:

Some little time ago I promised to tell about the bee-keepers' paradise in Texas. I have this on the docket, and it will appear as I take up the line of my travels. But since running across that paradise I have run into two or three others. There is one west of the Rockies, in Colorado, that is not yet stocked with bees or bee-keepers; another one in Central Idaho—in fact, I do not know but the whole State. These will be described in turn. The fact is, millions of capital are being invested in irrigation; irrigation means alfalfa; alfalfa means a paradise for bees. But I found all along my trip that alfalfa-growing preceded bee-keeping by two or three years, for it seems to take about that length of time before bee-keepers find these gold-mines that have been hitherto unoccupied.

If you are dissatisfied with your present location, and for financial reasons, or on account of health, will be compelled to leave, subscribe for Gleanings in Bee-Culture, and learn something about the great South and the great West. There are many locations in the West that are not yet occupied—splendid bee-locations. If you wish to learn about them, send 25 cents for a six-months' trial subscription, or $1.00 for one year and one untested Italian queen. Or, send $2.00 and we will send Gleanings one year and one of our celebrated Red Clover Queens.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-label. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one of [the buttons] as it will cause people to ask questions about the bee-keeper, and many a conversation thus started would wind up with the sale of some bees."

There is an extra opportunity to enlighten many a person in regard to honey and bee-keeping in general.

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to beekeepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; 6 for 50 cents. Send all orders to the office of the American Bee Journal.
The Buffalo Convention opens a week from next Tuesday evening, Sept. 10, in the Lecture Room of the Buffalo Library Building, at the corner of Washington and Clinton Streets, near the business center of the city.

We are looking forward to the largest gathering of bee-keepers ever held in the East. Chicago has set the pace, there being about 500 in attendance at one evening session last year when the National convention met here. There never had been anything like it, we believe—or at least not during the past eight years, as we have attended every national meeting during that time.

There are to be no papers read at this Buffalo convention. All the time is to be consumed in the discussion of questions. Such an impromptu program often proves to be one of the most interesting and profitable, when properly conducted. At least, the Chicago Bee-Keepers’ Association has found it so. But the main thing just now is to begin to get ready to go to Buffalo.

Pictures of Apiaries.—Some time ago we called for photographs of the apiaries of our readers, and quite a number have been sent to us. They will be used as time goes on. But we want more of them. If you have a picture of your apiary, why not send it to us? If it is not good enough to make a creditable engraving, we will tell you so, and return it, if you so request.

When sending, please remember to write your name and address on the back of the photograph, to avoid mistakes after we get it. Sometimes we receive several at one time, and desire to use every precaution to prevent errors.

Too Much Room in Spring has made sad the heart of H. H. Hyde, as he relates in the Progressive Bee-Keeper. It is the custom in his part of Texas to leave all the extracting hives on the hives during the winter, as the easiest way to take care of them. He says:

I had been drifting along like the balance, giving the question very little thought until this spring, which was a very late, cold, backward spring—the bees being very late and dilatory in breeding up. I very soon noticed that the single-story colonies, or such as had only as much room as they could occupy as needed, were outstripping those that had a large surplus in room. Single-story colonies soon built up strong and ready for the honey-flows, while the others were dragging along, and for a good part of the time only holding their own, the result being that when the spring blooms were in full vigor and there was no position to harvest the honey crop, I think that this has taught me a valuable lesson, and I am going to give every one else in this part of the country.

It is not difficult to understand why a colony should not do well in winter or early spring with a large empty space above it. It is too much like being outdoors. Heat rises, and in the winter time a thermometer will show the upper part of a living-room several degrees warmer than near the floor. If it is thought desirable to have vacant room in cool or cold weather, let it be below and not above.

Some Big Reports are assembled in The Pacific Bee Journal, including just a little to discourage bee-keepers in regions less favored than California. Emerson Bros. increased from 855 to 1,000 colonies, and took 40 tons of honey. C. A. Pyle increased 70 colonies to 102, and took 14 tons (100 pounds per colony.) J. B. McClure started in the spring with 230 colonies, and took 45 tons. A. Joplin with 225 colonies took 24 tons. G. Donbrowsky took 14 tons from 170 colonies, spring count. Merrier & Son, 50 tons from 255 colonies.

The Price of Honey is something that the bee-keeper sometimes finds it hard to settle upon. He is at a loss to know what price he should charge for his honey, or to sell it to a grocer or a private customer. It is a clear case that if he is to hold the trade of the grocer it will not do to sell to private customers as low as to the grocer, and it may be the better way to sell at retail at the same price as the grocer. But what shall determine the price to the grocer? G. M. Doolittle, in a conversation in Gleanings in Bee-Culture, discusses the matter very sensibly as follows:

Find the quoted price for each grade of honey which you have, in the city to which you would send your honey, did you ship any away, and then figure the expenses for freight, cartage, and commission out, and you will have what it is worth at your nearest railroad station. For example, the rates on comb honey from Skaneateles to New York City is 50 cents per 100 pounds. As this is cross weight, we find by a little figuring that about 55 cents per 100 pounds is what the freight will cost, and the cartage will bring it up to 60 cents. Quotations during the months of July and August are generally little more than nominal; but from them we will guess that fancy honey will bring from 13 to 15 cents this year. But unless your honey is exceptionally fine I should not put it above 14. Then as most commission men charge 10 per cent for selling, we have 14.40 as the cost of selling 100 pounds. This, added to the 60 cents freight and cartage, makes a cost of about 2 cents per pound to get our product to market, and the cash for it in our possession, so that, on the basis of these figures, if you can not sell the honey you have to Skaneateles and other places for under 23 cents per pound, you had better send it to New York.

"Well, I had never thought of reasoning it out in that way. I thought I ought to have 13 cents for it, or only one cent less than New York quotations."

It is an old saying, that ‘a nimble sixpence is better than a slow shilling;’ and I fear you will find that your honey will go very slow at 13 cents, while it would sell rapidly at 12 cents. Then there is a possibility that, when the market comes to be established this fall, honey may go still lower than the nominal prices we have used in which case it would be better to move it off rapidly by putting the price at 11½ cents, where a party will take a whole crate.

One phase of the case, however, Mr. Doolittle does not touch upon. In some places and in some years it happens that the local supply is so short that grocers send to the large cities for their supplies. In that case the bee-keeper would be foolish to follow the same rule as in years of full supply. It may be that grocers in Skaneateles never send to New York; it is certain that grocers within 100 or 200 miles of Chicago often send to Chicago for their supply. For the sake of illustration suppose the same thing should occur at Skaneateles. The crop is short, and the bee-keeper, following the general rule, sells to the grocers the few hundred pounds he has at 12 cents, the New York price. When these few hundred pounds are exhausted, the grocers must send to New York for a further supply, paying 60 cents per hundred freight, making the cost a little more than 14½ cents per pound. By what rule of right should the bee-keeper sell to the grocer for any less than this price? If he sells at 12 cents he is losing 2½ cents on every pound he sells. So when the crop is so short that part of the grocers’ supply must be secured from the large cities, the rule should be, not to deduct freight, commission, etc. from the city price, but to add to the city price the amount for freight.

Foundation Splints (instead of wiring brood-frames) have been warmly advocated by some bee-keepers. Splints about one-sixteenth of an inch thick are soaked in hot wax for the purpose. B. F. Averill says in Gleanings in Bee-Culture that he does not find it necessary to have the splints coated with wax. He merely presses the wooden splints into the foundation, having them longer than the inside depth of the frame so that the ends of the splints rest in saw-kerfs in the top and bottom-bar. They are put alternately on opposite sides of the foundation, six or seven to a frame, and no other fastening for the foundation is needed. One advantage is that the foundation is built right down to the bottom-bar.
Contributed Articles.

A Trio of Questions—Bee-Book Reviews.

BY PROF. A. J. COOK.

I REGRET if any one has questioned the wisdom or courtesy of my reviews of the bee-books. I believe we all—Dudant, Cowan, Root, and myself—wish only the truth. If we have made mistakes—and, of course, we all have—we are only too thankful that they be corrected. I always rejoice with exceeding joy at any kindly criticism of my books, or my journalistic articles. As Mr. Root said, I am not always right. If any earnest student thinks me wrong, I like to know, that I may re-examine, re-test, and very likely find I am in error. Then how quick I will be to correct; I am sure all our authors in question are of like mind.

There are two good reasons why these criticisms should not be withheld, viz:—
1. It brings mooted questions before us to be studied and rapidly decided.
2. Though possibly corrected in latest editions, the hosts have only the older editions, and surely they are entitled to have their text-books corrected.

BEES EVAPORATING HONEY IN TRANSIT TO THE HIVE.

The criticism of my position on this subject warrants reply. Surely, I seem to be almost discourteous and dogmatic, when I say, "I know bees never do this." I do not mean to call in question the truthfulness of those who claim to have seen the falling mist. I have never seen it, though I have tried to discover it often. When I say, "I know," I refer to the appended theory, "Evaporation of the nectar. If some one should report seeing a bee carrying a large drop of honey, and should add that he believed in an iron wedge weighing a pound. I would have no right to doubt the first part of the statement. I would have a perfect right to say I know regarding the second part.

The body holds the water in solution. It is a close integral part of the liquid. It can only be separated, so far as we know, by force, heat, or centrifugal motion. The bee can not possibly exert any of these on nectar within its honey-stomach. The statement of falling mist we may not dispute. The impossibility of evaporation we may affirm, and so say "we know." I repeat, if such droplets do fall from the bees, they are fecal, or respiratory—shall we say secretions?

KILLING BEES TO STING.

I also speak with a sort of offensive dogmatism on this point. I have over and over suggested to my students to perform the following experiment:
With a glove on anger the bees, till a dozen, more or less, sting the glove, and actually pull out their sting. Then they were to catch as many from the combs by taking hold of the wings. Each lot was put into a cage provisioned with honey or "Good" candy. In a few days all of the first lot would die, while all of the others would live for weeks. Often the second cage was peopled with bees taken as they were about to fly from the hive in quest of nectar.

This explains why Mrs. Clark's bees that stung her cow to death were so generally destroyed. She reports that her apary was seriously depleted, while thousands of bees were dead near the carcass of the cow. We all know that bees may sting and not lose the sting. Of course, such cases may not prove fatal.

SCIENTIFIC USE OF TERMS.

The dictionaries are conservative. They allow expressions which experiment would permit. Physiologists do not confound digestion and assimilation. It would not be exact, and so would be unscientific to do so. Is it not wise to go to the best and latest specialists in physiology for our definitions? I say that digestion is to fit the food for absorption; and that assimilation has to do with metabolism or tissue changes. The entomologist is wise in not calling a larva a worm, for it is not. The entomologist might possibly use the term miller for moth; it would be rare, however, but be surely would not say moth-miller. He would as correctly speak of a female woman. Are we not wise to consult the up-to-date specialists in our use of scientific terms?

[The above article was received at this office the latter part of May, and through some unexplainable way was overlooked until now. We regret the long delay precedingly, but trust it has not entirely lost its value.—EDITOR.]

Valueless Figures as Applied to Bees—In-Breeding.

BY G. M. DOOLITTLE.

FREDERICK B. SIMPSON is one of the comparatively new writers for the bee-keepers, yet his articles are full of mortal errors. He seems to be one of those authors with which a queen-mate is entitled to probably the same share in the results [greater, in my opinion—G. M. D.] as the queen's mother, and also that the mother of the drones with which the breeding queen's daughters are also entitled to some share, his figures are of little value.

Just so. And even at the risk of appearing "sassy" I wish to say that his, "whereas the real cause of quality is ignorance, and not the possession of the original selection," is quite incorrect. The bee-books of the highest authorities would be the one to judge with which a queen-mate is entitled to probably the same share in the results [greater, in my opinion—G. M. D.] as the queen's mother, and also that the mother of the drones with which the breeding queen's daughters are also entitled to some share, his figures are of little value.

I, in the American Bee Journal for June 20, Mr. Doolittle gave us some figures, but as he has not corrected them, I think the one should be proved to be hereditary in each pedigree, as given in his "in-breeding" article, are equally of little value, as applied to bees. And all the illustrations which have been given in the bee-papers during the past 30 years, no matter by whom given, as comparing the breeding of horses, sheep, poultry, or swine, with that of breeding queen-bees, have been equally valueless, for there is no common ground (on which to stand) between them.

Suppose Mr. Simpson, with all his horse knowledge, was asked to turn out a mare out of a 10,000 acre forest, filled with twice that many stallions of all grades, sizes and colors, she going way out of his sight and hearing before she met even a single one of them; of how much does he think it is? (2) When I read that a custom is to be hereditary in each pedigree, or about the "mother of the stallion with which he mated?" The fact is, the breed of queen-bees is the same the opening of the selection of drones, and all talk along the line of what drone any queen mates has no value attached to it whatever.

I have had a standing offer, outf or years, of $500 to the man or woman who would give me a practical plan whereby I could mate a queen-bee to any individual drone, with the same certainty that a horse-bred cosmic could make his stock. And I know of several other queen breeders who would give that from that twice that amount. Here is your chance, Mr. S. And not only a chance to get the $500, but also to prove the head of the best breeders of present and those who are to come after us during the centuries yet to come. And, until this problem is worked out, it is useless to talk about "hereditary," "skilful selection," how stupidly, how scientifically, and esthetically, or anything of the kind. And the "great big tent" plan, lately agitated, should it prove successful, would not at all meet the requirements of the Simpson horse-breeders, nor claim my $500 for that would be like turning out the mare, in the supposed case, into a forest containing from 50 to 1000 stallions, with the simple guarantee that they were raised from one mother. Some would be weaklings lacking some or all lines, lacking of proper form, proportions, etc., and would be something that no careful breeder would ever listen to, although it might be somewhat of an improvement over the first, or what we now have.

Those who have accused the present race of queen-
breeders of simplicity, and lack of insight into matters which go on behind the scenes. A, Mr. Simpson, why the regular contributors to the bee-papers have not shown any desire to give us any specific aid on this subject, is, because, under the present state of affairs, there can not well be. The present condition of the bees, and millions of drones, from scores and hundreds of hives, within a circle of five to ten miles in diameter, all congregating together, as the stallions in the forest, there is very little chance that any queen could possibly mate with a drone from her own mother. But suppose she did? Does not Mr. S. know that it would be only her mating with a half-brother? The drone is "the son of his mother," while the queen is the daughter of her mother and father. And as the drone is always, practically speaking, the son of his mother, in-breeding could be carried on for several generations, even with a full control of both queen and drone, before we could practically mate a brother and sister. And with the present conditions of mating, and the dearth of drones, there is no chance that it is simply folly for beekeepers to talk about in-breeding, or to say very much regarding the mating of the queen's way, as to what drone she mated with.

The very best I have been able to do on the drone-side, has been to keep a lot of drones from my best breeder, not nearly akin to the queen-mother, till fall, after other drones were killed off, then "hand pick" them, cutting out all the inferior ones, when I had some reasonable assurance that queencrowd was good. This was tried with some of these drones, providing that some other colony within the circuit of the flight of "drone and queen," did not have a failing queen, or was queenless, in which case there would probably be hundreds of drones from such a colony to where there was tens of my hand-picked specimens.

I spent much of the time during the later seventies and early eighties in trying plans for the control of fertilization, thinking them out nights and trying them days, besides nearly all the plans advised by others, and after having thought them out carefully? I finally settled down to try to do the best I could from the queen-side, which thing I have been doing ever since. But I am free to admit, with Mr. Simpson, that, if I could have had control of the drones, all the mate of the queen during all these years, there would have been more "value in the figures" than there is at present; although a yield per colony of from 60 to 90 pounds of comb honey from red clover this year, with little or nothing 20 years ago, proves that I have not labored entirely in vain.

Onondaga Co., N. Y.

No. 12.—Practical Lessons for Beginners in Bee-Culture.

BY J. D. GEHRING.

One of the most serious of the short-comings among those who keep bees on the farm, is that they don’t know what to do with them in case of sudden emergencies. Robbing is one of the worst of these, please remember, Mr. Bond. Even if you reduce the present number of your colonies, as you now contemplate doing, down to one or two, you will need to be informed on this subject in order to be ready for business when the bees furnish the occasion.

A few years ago I sold a colony of bees to a man who lives two miles from here. If it had not been for the fact that his wife was crazy to have some bees, but didn’t know anything about managing them. But as he knew how, and wasn’t afraid of them, he thought they could risk it to begin with one colony.

Well, he took the hive I sold him home early in April. It was one of my best colonies. I instructed him how to make the bees mark their new location, and how to manage when a swarm should issue—the colony having a clipped queen.

A large swarm was secured all right some time during the month of May, and the queen taken care of according. But it was necessary to put another queen in, and I went and showed him how to put them on. All seemed to go well, except that no honey was stored in the supers, save a few pounds during the late season. I also instructed both of them one evening how to prepare the colonies for wintering, either in the trees, or in the cellar.

"Well, they thought I would be a capital idea to try both methods of wintering, so he carried one hive—the one containing the new swarm—into the cellar, leaving the mother colony out in the cold. The phrase, ‘out in the cold', is one severely emphasized by the fact—but I known to me till the following spring—that my friend neglected to carry out my instructions as to how the hive should be prepared for the outdoor siege. He didn’t even have time, he said, to take the sewer of nearly empty sections off before cold weather set in.

"One day in early April he came to me and requested that I should come and tell him what ailed his bees. The old colony, he said, was about played out, and the other hadn’t seemed to act right since he had brought it out of the cellar.

"When I had finished examining those hives I found no queen in the latter, and not a spoonful of honey in the former. Much I found four of them huddled together there. I told him to feed the honeyless bees at least a pint of syrup a day until fruit-trees were in bloom; and if more necessary, I furnished him a feeder and full instructions with. But that was all of little use again—about two days later. His wife thought it was too expensive to feed bees so much syrup; and, he, being more liberal, thought it took much too much. These points I got later, and from an outside source.

"Failing all else, he furnished a frame of brood, put it in place for him, and cautioned him to watch the hive very closely until a new queen could hatch out. He didn’t do it, although I had fully explained why it would be necessary. Then the colony, I am sorry to say, was destroyed.

"One day, soon after giving him the foregoing advice, he sent me word by telephone to come up as soon as possible—the bees were robbing. When I arrived on the scene an hour later I found the reverse of his statement to be only too true. The colony had been robbed! Not only the honey was gone, but all the bees also.

"On inquiring for particulars, I learned that early that morning the colony seemed to be all right, and busily working—‘lots of bees in the hive,’ he said. Here, then, was an entirely new—even to me—feature in a wintering success, which I couldn’t understand better than that, after realizing that resistance was useless, or worse, that colony of bees made a full surrender, filled up with honey, as they do when about to swarm out, and went with the robbers in a body. This is not to say that there were no robbers, there was. There was no other sensible explanation, as but a few dozen dead bees were found near the hive, and none in it.

"Before I left for home I requested my friend to show me the place in the cellar where the colony had wintered. There I found the solution of the case of the robbing: the dead queen on the cement floor of the cellar, among perhaps one-third of the bees, also dead! The foolish man had neglected to screen the bee-entrance, and had given the bees no ventilation in the hive; and he had also neglected to see to this until to this day, those people can’t understand how it was that I had an average, the previous season, of 75 pounds of honey to the colony, while they, only a mile away, and with two colonies of bees, did not produce even 50 pounds.

"I have related this case in detail, Mr. Bond, to show how absolutely essential it is to attend to all the details in the management of even one colony. It is even more important when you have one or two only, instead of 50, because, you lose one, or both, you are out of the business entirely.

"That’s a very interesting case," remarked Mr. Bond; and instructive, too, as far as it goes. But in telling the story you failed to tell me just what you did to those hives. Did you screen them for winter, each in a different way and place. I think I ought to know those details," concluded Mr. Bond.

I should have overlooked that fact if you hadn’t mentioned it," I replied; "and it’s the really valuable part of the story to you, too. Well, I can repeat the substance of
What I told that friend to do, and you can apply it next fall when it's about time to prepare your new colony out there for winter quarters, either outdoors, or in the cellar.

"Be sure to avoid, at the outset, the too common mistake of waiting with the winter-preparation work until cold weather has set in. Here in Kansas it is generally safe to wait until the middle of October—seldom as late as November.

"The first thing you must do has to be done whether the colony is to remain on its summer-stand, or to be transferred to the cellar, and that is this:

Prepare your bee-smoker as I have already shown you. Then you put on your bee-veil, remembering that at that season of the year the bees are much more touchy and liable to sting than during a honey-flow. Then you take your smoker and go to your hive. You have already given the bees a full blast in your hand. If you prefer to quiet the bees before beginning operations you rap sharply a few times on the outside of the hive. Then you wait about five minutes for the bees to circle about their hive. Then remove the cover in order to get at the super, which I will suppose you put on in time to catch the late surplus honey. This super you then take off, in the manner I have shown you, and set it, for convenience, on top of the hive-cover, where it is safe—if securely covered—until the rest of the job is done.

"You are now ready to loosen the ends of the brood-frames, with the tool you have brought with you for that purpose, and blowing a little smoke over the top of them while doing so, should the bees crowd to the surface and get in the way.

"When this is done you begin the real business to which the foregoing was merely introductory; namely, you begin in the middle of the brood-nest and take out the frames, one by one, examining each in succession to find the queen. It is the queen you are really after, more than anything else, because the prime object of this whole performance is, to ascertain—not to guess at, as many keepers of bees do—the fact that the colony has a queen. It is very important for you to be sure of this, not because the colony couldn't live through the winter without a queen, for it can; but because you then begin to look about for operations in early spring without a mother-queen. You could not, of course, very well go through such an operation in February or early March in order to find out what you should know before you shut the hive for the winter. I hope you'll never forget that, Mr. Bond.

"Of course the fact will suggest itself that, after you have found the queen, and have estimated the honey in the frames to be fully sufficient to last them till spring, you replace all the bees and cover them snugly with a piece of fine burlap. You then put a rim—an old one, or one that you have cut to suit the weather at the time, and your work is done for outdoor wintering in Kansas.

"For cellar-wintering you do no packing on top. Neither do you take the hive to the cellar before cold weather has begun. Then you remove the entrance-blocks and tack a piece over the brood-frames for the same purpose. Prepared in this manner your bees are safe in a dry cellar. But if the cellar is too cold—that is, below 45 degrees at any time—a piece of burlap or a piece of old carpet over the screen on top of the frames. It will keep them warm without depriving them of needed air.

"As a matter of choice, the frames are placed in the cellar, always with the exposed faces toward the cold, but in the south, where there is not much difference in temperature, it is often better to put them in the north.

"And do not keep your bees in the cellar without a good supply of water. If you have a cellar, put it in the corner. If you don't, make a hole in the floor and fill it with a box of water. Do not let the bees pass through the cellar, or wash them unless you have a spare room for them.

"Here endeth the lesson."

Mr. Bond took dinner with us and then departed for home, having left his colony of bees with him, as happy as he had ever known a farmer to be.

(The End.)

---

**Questions and Answers**

**CONDUCTED BY**

**DR. C. C. MILLER, Marengo, Ill.**

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

**Mulberries for Bees.**

What Dr. Peiro says on page 525 leads me to think that it is possible there may be two kinds of white mulberry, and if any one is thinking of planting largely it would be well to make sure of having the kind that he speaks of as bearing luscious fruit. In Pennsylvania I was familiar with the black mulberry, of which I was very fond. When I came to Illinois I found white mulberries growing wild (not in this county, but further south), but the fruit was insipid, and to my taste hardly fit to eat. I do not suppose it would be difficult to get bees to work on the crushed pulp of mulberries or any other fruit, but the question is whether what the bees would store therefrom would pay for the gathering and crushing. It would probably take a good deal to make old bee-keepers believe that bees could store good honey from the pulp of any fruit.

C. C. MILLER.

---

**Milkweed Pollen-Masses on Bees' Feet.**

I send a sample bee. By using a microscope you will see a foreign substance attached to its feet, which prevents walking or working. The other bees are pulling them out, and carrying them off in large numbers. What is it? What particular plant or flower do they get it from?

- PENNSYLVANIA.

**Answer.—** The milkweed is the culprit. *Aesclepias Cornuti.* The pollen-masses become attached to the feet to such an extent that the bees appear not to be able to climb upon the combs. At any rate, their sisters drive them out. It is possible that enough is gathered from the milkweed more than to pay for the damage done; at any rate the loss is not serious, and there is nothing you can do about it.

---

**Loss in Introducing Queens.**

A queen sent me arrived in good shape, and I introduced her according to directions, but the bees did not receive her. I have kept the colony supplied with fresh eggs to prevent laying workers, if possible, and to give them a chance to rear a queen, but the queen-cells they have started have all been with eggs that were too old. I examined them carefully before I introduced the queen, and destroyed all their queen-cells, and I am very sure there were no laying workers.

1. Do you suppose the presence of fresh eggs in the hive would prevent the workers from laying?
2. What is my trouble? — NEW HAMPSHIRE.

**Answers.—1.** Laying workers are not likely to occur if the bees are kept supplied with eggs or young brood. 2. In asking what is your trouble, you probably mean to ask what was done wrong that resulted in the killing of the queen you were trying to introduce. Perhaps there was nothing at all wrong on your part. The attempt to introduce a queen is not always successful. Nineteen queens out of twenty may be accepted all right and the twentieth rejected, although exactly the same plan was used with the twentieth as with the other nineteen, and no one can tell just why the twentieth failed. I don't understand what you mean by saying they started queen-cells with eggs that were too old. When bees are without a queen they rarely start queen-cells from the egg; nearly
always from larvae; and an egg could not be too old unless dead. Neither would they start a queen-cell from too old a larva if constantly supplied as you say with fresh eggs. But the presence of eggs and young brood would be no help toward the acceptance of a queen, for they might think they could rear a queen of their own, and thus reject the one offered.

If you want to take the trouble, you can make the acceptance of a queen a sure thing. Take two or three frames of just-hatching brood, with no unsealed larvae, put them in a hive without any bees, put in the queen and shut the hive up bee-tight, and keep it for five days in a warm place in the house, or over a strong colony with wirecloth between, so that the heat but no bees can pass up through. You can make sure of frames of the right kind of brood by putting frames of brood eight days in advance in an upper story over a queen-excluder.

Late Swarming.

July 25 I opened hive No. 1 and killed the queen; July 27 I gave a new queen to the colony, and Aug. 10 this same colony swarmed. I caught the queen and had the bees to return to their hive. Two days later I opened the hive and found one queen-cell; I cut it out, and handed it to my daughter, when, to her surprise, the queen left the cell and was born, as it were, in her little hand. I caged the young queen and returned the old one.

1. Now, why did they swarm so late, when the flow is almost over with us here in Pennsylvania, and starvation staring them in the face?

2. Is the young queen of any value to me, as I see no drones flying any more? Pennsylvania.

Answers.—1. You do not say whether you know that the queen which you caught Aug. 10 was the same one you introduced or not. It is possible it was the same, and that the bees were nearly ready to swarm when you introduced her, but the break in laying postponed their action. The flow being near its close would not hinder the swarming, so long as the flow continued, for the bees might expect it to continue indefinitely. If, however, it was a normal prime swarm, the old queen issuing with the swarm, a young queen would hardly have issued from the cell so soon as two days after the issuing of the swarm. It is more likely that the queen you introduced was killed, and that a young queen issued with the swarm, for when young queens are reared upon the killing of a queen, the colony is likely to swarm when it might have had no notion of swarming if the old queen had remained. Bees seem to be more reckless about swarming with a virgin than with a laying queen.

2. The young queen is probably all right. Even when you think all the drones are killed off, a few are still likely to be flying until cold weather actually comes. Indeed, they are sometimes allowed to go into winter quarters.

Fall Transferring.

I have several colonies of bees, purchased in box-hives, and I want to transfer them to dovetail hives. Would you advise me to do so immediately, or would it be preferable to wait until spring? California.

Answer.—You will probably do well to wait till spring.

An Introducing and Swarming Experience.

1. I had a colony swarm a week ago (June 15,) and when I hived them everything seemed to go all right. But, alas, towards evening they killed their queen, so I let it stand a day and I introduced a laying queen. But they killed her, too, so I was almost crazy, because it was a valuable queen. So I got a little hybrid queen, laid her above the frame for a day, and then I put her in an introducing-cage, but they would not eat her out. So I let her out myself, and she went to laying. Now the point is this: Yesterday they cast a big swarm. What was the object of their swarming? They had the old queen with them, because she was clipped. They have five sealed queen-cells. They had supers on, and lots of ventilation, and they had not worked in the super very much.

2. Do you think they will go right to business? There was a flow from basswood and button-ball. Illinois.

Answers.—1. I don’t know. When a strange queen is introduced, either because the bees are not quite satisfied with her, or for some other reason, they very often start queen-cells, and when these cells are sealed they sometimes swarm. But if I understand you correctly, these cells were in the hive of the swarm, and they were sealed within a week after the swarm was hived. This could not be, unless you gave a frame of brood to the swarm, in which case cells were probably started at once when the brood was given. Of course, these cells were not started from the egg, but over larvae already there, and cells being called post-constructed or emergency cells. 2. Very likely they will now settle down to business.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last.
RUSTLER BEES AND AVERAGE BEES.

Among the two pen pictures of the rustler bees and the average bees, on page 462, I hardly know whether to applaud or scold. Guess I’ll scold. It seems to me that where colonies are not queenless, not excessively weak, and nothing special the matter with them, the working of the bees does not differ very greatly—or if it, does the keeper needs a thrashing. Mr. Schaeffer, hadn’t the heads of those average queens ought to come off—that the heads of their grandmothers ought to have come off long ago?

**The Home Circle.**

Conducted by Prof. A. J. Cook, Claremont, Calif.

WASTE-PAPER BOXES.

Our good friend, that prince of California bee-keepers, J. F. McIntyre, has left his canyon home, which has harbored him and his for near a score of years, and has gone to the city, which in the future is to be honored by having him as a citizen.

What could lure him from the restful quiet of that grand canyon, where he has always had Nature at her best, and at first hand? Then, too, his bees, which he loved so well, and has cared for so fondly and so wisely, must be left behind. He and the ripple of Wespe must part company. This, at times, was a rapid, roaring, resistless torrent, which then swept grandly by his very door. This Grand and no less beautiful environment must have become very dear to all the McIntyres—must have crept in with its refining, elevating influence to more rugged the honesty, more prompt the sympathy, more pure and high the aspirations towards better things. How could they leave such environs? Why did they hie away, even though it was to move to a beautiful city by the sea? It was not to change grandeur for grandeur, the close mountains for the equally close ocean, whose surf is ever beating the shore, and whose breakers are ever chasing each other landward, as if tired of their own restless plunging. It was a good purpose—that the dear children might have better school privileges.

Oh! but this love of children is a most blessed thing; though it call for heaviest sacrifice, its call is not in vain, but gladly heard and heeded. Mr. McIntyre, as in all his relations, shows here his good sense and wisdom. Education—the best—is the most precious treasure he can bestow on those lovely girls. To sacrifice, that such treasures may be granted, is the greatest gain. Those fortunate daughters will ever remember it gratefully—the justly proud parents will ever rejoice that they could do this good thing.

Well, I, too, have tasted our friend’s kindness. I drove myself during the cool evening eastward to meet several of the ranchers in the rich, beautiful “Mound District.” And the next morning he accompanied me to look in upon the incomparable begonias of Mrs. Theodosia Shepherd, who by her wonderful skill in breeding plants and developing new varieties, has gained a world-wide reputation. How much pleas-...
Surely, the city, in maturity, train and throw and daughters saw the whole God and Native paths, the fair must be on the streets, and show my appreciation of these fair daughters of fair Ventura. The half-filled boxes, and the neat paper-and-rubbish-free streets show full well that the ladies' efforts are not unheeded. This means a whole lot more than clean, tidy streets, it means a toning up of the whole child population of Ventura. Need I limit it to the children? We children of larger growth need just such toning up. If all parents had time and inclination to instruct the children never to throw the paper-scraps, the banana peel, or other filth and rubbish, into yard or street, then our walks, paths, streets and yards would be a "a joy forever," and not the unkept reservoir for rubbish and rot that so often offend and disgust us in our strolls and rides.

As we parents are too often remiss in this, or else fail to impress our wishes, it is good that such as the Ventura Native Daughters should come to the rescue. May we not all take a hint from them, and go and do likewise? As also do all we may by word and more telling example to aid in this good work of a wholesome cleaning up? Surely, Ventura is happy and fortunate, in having this ever-present reminder—I should have said reminders, for these boxes are very plural—not to throw the litter on walk and street, and to pick up any that more thoughtless, careless hands have cast away to disfigure the landscape.

How many of us, as we see the disgusting scratch of many matches on beautiful walls, or see the scattered matches on floor or walk, rejoice that the fond, eager, loving mother in the long years past, busy though she was almost to the limit often of strength and endurance, yet was not too busy to train us in better and neater ways. The little child that is so taught that it will never mark a wall, never scratch a match where it will mar and disfigure, never cast the refuse paper or fruit-peel where it will offend good taste, has received a lesson that will make it more a lady or gentleman, as it comes to maturity, and more a patriot as it pushes out to live life's battles. I feel sure that one taught care and thoughtfulness in these matters, will have such respect for law and order that it will take great temptation to move him to join mob or engene in riot. Surely, such teaching must be rife in all homes of Ventura. For only from neat homes could come the impetus that fixed those boxes on the many street-corners of beautiful "Ventura by the Sea."

I wish these words might move others to act for home and elty, that we may become a neater people in our home, as also in our suburban life.

PROF. L. H. BAILEY.

And do some of you—not too many, I am sure—ask, Who is Prof. L. H. Bailey? Well, he is an old friend and student of mine, who by hard, earnest work has become known the world over. He is perhaps the most noted and best known horticulturist in the world. He is professor in Cornell University and has written some of the best books on growing and caring for fruits that are to be found. He is also at the head of the great movement in New York State that has succeeded so gloriously in taking "Nature Study" to thousands of children in the rural and city schools. He has inspired the teachers to this same nature study, so that they can interest the children.

And not content with this, he has pushed on to the farmers and has inspired them a desire to know more and much of nature. So that thousands of them are again in school, so to speak, and are happy in quest of truth as found in study of plant, insect, soil, and rock. This nature study, as carried on in New York, is full of promise. It is making life fuller, brighter and better in thousands and thousands of homes. Prof. Bailey even prepares the leaflets and booklets that are to be used as lesson helps in this grand quest of truth. More still, he either goes or sends some one to schools and homes, to give added help and inspiration in this great and beneficent work. May we not pray that the Lord of the harvest may send more Balies, and may we awaken to more nature study every section and State in our beloved country.

I have had Prof. Bailey lecturing with us for two days in the University Extension work in agriculture. It was a great treat to hear him, and the great audiences just hung on his words. Prof. Bailey says his whole life has been turned, brightened and tremendously influenced by a lady teacher, whereby early in life he was led to study the tree. I visited his home while he was but a lad, and was delighted to find him authority on all the birds of his neighborhood. Later it was my delight to be for four years his teacher, and to watch with profound joy, his leaps and bounds into the realm of knowledge. Will not the nature-study work, inaugurated in New York by Prof. Bailey, discover to the world other Balies who will walk in his footsteps, and thus multiply the glad fruit that is sure to come from all such well-directed effort?

The home circles in the great Empire State who have tasted of this blessed nature study fruit, may well help to incite other places and States to "go and do likewise."

LAKE IN THE PAN-AMERICAN EXPOSITION GROUNDS.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at $1.00.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.
ADVERTISEMENT.

To Our Shippers:

We were obliged to notify you a few weeks ago that one Joseph M. McCaul had leased our old quarters at Nos. 120-122 West Broadway, New York City, and had there started up business under the name "Hildreth, McCaul Co.," and had distributed a multitude of circulars so worded as to create the impression that his business was a successor to or a branch of the business of Hildreth & Segelken.

For the protection of our shippers and ourselves, we at once instructed our attorney to commence action to enjoin the said McCaul from using the name HILDRETH in any manner whatsoever in connection with his business. On the 10th day of July, 1901, Hon. David McAdam, Justice of the Supreme Court of the State of New York, after a full argument upon the merits, issued a peremptory injunction, of which the following is an extract:

"And it appearing that the plaintiffs have for a long time been and now are carrying on business under the style of 'Hildreth & Segelken,' and that the defendant has recently opened a business at 120-122 West Broadway, in the Borough of Manhattan, City of New York, and is carrying on the same under the style of 'Hildreth, McCaul Co.,' and that such act is in violation of the plaintiffs' rights, and that the commission or continuance thereof, during the pendency of this action will produce irreparable injury to the plaintiffs; it is

ORDERED that the defendant (Joseph M. McCaul) and each of his agents, servants and employees and all other persons acting under his authority and direction be, and he and they are hereby restrained and enjoined from showing, displaying or otherwise using during the pendency of this action in or upon any papers, devices, sign or signs, or otherwise, in the business conducted by the defendant at No. 120-122 West Broadway, in the Borough of Manhattan, City of New York, or elsewhere the name of "Hildreth" separately or conjunctively with any other name, designation or description."

Outside of our desire in our own interests to protect the name which we have built by years of satisfactory dealings with our customers, we hastened to procure this injunction as soon as possible, to prevent our shippers from being misled into sending their goods to one who would make an attempt to gain their trade by such a trick and device.

With thanks for the many expressions of good-will we have received from our shippers concerning this attempt to trade under our name, we are,

Sincerely yours,

HILDRETH & SEGELKEN,
265-267 Greenwich Street, NEW YORK, N. Y.
A Good, Growing Season.
This has been a very good, growing season here. I feel sorry for some as Dr. Miller and others who have suffered from lack of rain. If the Dorothy had sent her bees and pasture here last spring I think Nature could have furnished the liquid tonic to have kept them going. White clover was fairly good, and bees worked well on it; basswood the same. Buckwheat is to be heard from. There is a big honey crop this year, and as the weather has been congenial for its growth, we may expect a good flow of honey.

M. P. LOWRY.

The Outlook in Washington.
All the spring and to the first part of July it was very wet and cold here. All through the clover season the bees did not do much more than make a living, although they were very strong in bees, but now they are getting some honey from more than 50 colonies. I think some of my best colonies have about 50 pounds of honey to extract, but I think the honey-flow will be cut short considerably by the forest fires now raging. I have three days I have been out in the timber with several other men fighting fires, and I was surprised to see bees working on the flowers where the smoke was so thick that we could hardly stand it. But even if the bees do work in the smoke, I think it will cut down the yield some.

HANS CHRISTENSEN.

Don't Make Wild Honey Reports.
I think it is utterly wrong for beekeepers to make such enormous reports as, "A good year for honey," "Best honey-flow in years," "Honey-crop ever known," etc. Any man with brains in his proper place can very plainly see that all such reports have a tendency to lower the price of honey, and while some may be quite true, I fear a great many report too early, having a large crop in view, with perhaps two or three dozen colonies of bee foragers in the pasture where they plan to gather honey, and they find themselves minus their honey crop, and buyers don't care to raise the price after it is once down. Hence it is folly to report.

Beekeepers should put their minds on a level with the facts before them. We rarely see a beekeeper who keeps bees for business making such a whoop, whoop, humdrum boy! It is the still waters that are deep, and where we catch our largest fish. I caught 22 nice ones, Aug. 16.

P. W. STAHLMAN.

Ancient Ideas of Honey.
I send a clipping which would doubtless amuse the readers of the American Bee Journal.
We laugh at the assumed knowledge of things related much of three and a quarter centuries ago; but many of the notions which we cherish and hug to our bosoms at this dawn of the 20th century will appear as ridiculous to our descendants at its close.

Columbia Co., N. Y.
JAMES McNEILL.

The following is the clipping referred to by Mr. McNeill:

HONEY FOR SCHOLARS.
"Honey and bread was a great meat with Pythagoras and his Scholars, and counted a sufficient food for a rational life. For it keeps the body, and honey both nourishes much and also cleanseth away superfluous phlegm being asked by Augustus the Emperor how he lived so long! By nourishing (satieth he) my body with

UNTESTED Italian Queens Free

By RETURN MAIL.

For sending us One New Subscriber for one year, to the American Bee Journal, with $1.00, we will send, by return mail, a fine Untested Italian Queen free. This offer is made only to our present regular subscribers.

GEORGE W. YORK & Co.

41 & 46 Erie St.,
CHICAGO, ILL.

Honey, and my outward parts with Arla. The like answer likewise made Dumpsicron, being demanded the like question. Furthermore, it was a general matter in the word of the mark, as old men agree, to take care of the long, bright, cleansing their branches, opening their pipes, warming their stomachs, resisting putrefaction, restoring the sweet and recommendable blood. Raw honey is never good, therefore clarify it thoroughly at the beginning. It is also good to put a little thyme and other good herbs in the oven. Then may you boldly give it as meat to young children, to cold and moist complexions, and to those sickly old men, especially in Northern Countries, and cold climates, and in the winter months.—From Dr. Thomas Fergusson, 1765.

Poor Season for Bees.

It has been a poor season here this year. What little honey there is has no good taste and flavor. It is worth about 30 cents per pound. There is nothing but pollen for the bees to get now, but they seem to be making good use of it, and are rearing lots of young bees.

Lafayette Co., Wis., Aug. 12.

Dreadfully Dry.

We have had dreadfully hot weather here. The thermometer registered 112 degrees in the shade. It completely dried everything. A few drops of rain are coming from the west. The weather is much more favorable now.

W. T. STEPHENSON.

Very Short Honey Crop.

In this section of country, with not half a crop of bees to start with last spring, I have taken 238 one-pound frames, or sixty-five colonies, spring count, and increased to 15. The weather was very dry, and white clover and many other plants yielded almost nothing. I know of but one bee-man that has taken any honey, and he had 50 pounds from 13 colonies. The bees have come the bee-papers—and can't afford it, they say. They have just as good pasture and bees, although my bees work on the clover and wild flowers.

What I know about bees I learned from the American Bee Journal. I bought six colonies from one of those fellows that don't read bee-papers. I paid 90 cents per colony for pure Italian bees in 10-frame hives. They worked on red clover for 50 days. I get 15 cents per pound for honey, and have sold 182 pounds, and the rest will be gone in a few days. I sell it right. I know my honey is not bad, I give the good "old reliable " American Bee Journal full credit for my success, and lots of pleasure besides. Without it I, too, would have said, "It don't pay to take beepapers!" and keep bees.

Hurrah for the American Bee Journal! Pike Co., Ohio, Aug. 12.

J. M. West.

An Experience in Bee-Keeping.

Three years ago I sent to a Tennessean for four 2-frame nuclei, at $2.50 each, after being assured that the express charges would not exceed 45 cents apiece; but when they arrived there were $7.50 express charges on them, and one of them was dead, and, of course, died. I never could hear from that firm again, although I wrote several times to them.

The other three nuclei built up strong, and filled the eight brood-frames. They wintered on the summer stocks all right, and the next spring, about June 1, they commenced swarming, and they did everlastingly swarm. I was away from home, and no one had any experience with bees, had her hands full. She succeeded in hiving six swarms, and she says five or six got away. Was a result of excessive swarming the original colonies were reduced so that they did not store much

QUEENS

QUIRIN— THE QUEEN-BREEDER — has now on hand, ready to mail, 500 young, long-tongued Red Clover Queens, Golden and Leather Colored.

We have one of Root's best breeders from his $20, long-tongued, Red Clover Queen, and a Golden Breeder which we are told worth $400, if there is a queen in the U.S. worth that sum. J. L. Gandy, of Humbolt, Neb., tells us that as the colony he had saved after five years, is now 400 pounds mostly comb honey in a single season. A. L. Root's folks say that our queen is extra fine, while the editor of the American Bee Journal tells us that he has good reports from our stock from time to time.

We have years of experience in mailing and rearing Queens. Queens positively by return mail from now on. Prices for balance of season as follows:

<table>

honey. We got about 50 pounds of comb honey from the new swarms, but none from the old colonies. Two of the old ones became queenless, and died during the summer. The seven remaining colonies wintered all right on the summer stands, but last season they did nothing. I got no increase and no honey, and they were light in the fall that I did not expect any of them to survive the winter. I think that fully 50 percent of the bees have been lost in this way during the winter. But by feeding mine pretty liberally during the warmer days of winter and early spring, all they came through in pretty good condition, and, notwithstanding that the extreme wind, heat, and drouth, my bees have done much better than could have been expected considering the very unfavorable season. They have increased just 100 percent, and most of them are beginning to work in the supers.

One of the old colonies, I think, is queenless, at least I have failed to find any queen, although I may have overlooked her. They have considerable honey and unhatched brood, but no newly laid eggs. I found quite a number of old, torn-down queen-cells, but no new ones.

N. A. CHEENEY
Barton Co., Kansas, July 25.

Drout and Heat in Iowa.

The drouth and heat have been hard on bees. Our hives are holding swarms after being hived. I got three swarms from one colony in five days, and they are doing well for a change this year. The forecast for the season was good, the bees having harrassed and white clover to work on. I am in a good location, on the Des Moines river.

**A Superior Red Clover Queen**

(An Unstained Italian)

For sending us One New Subscriber and 25 cents ($1.25 in all.)

We arranged with one of the oldest and best queen breeders (having many years’ experience) to rear queens for us this season. His bees average quite a good grade, and the largest tongues of any in the country. The breeder he uses is the best from Italy, having imported her himself. Her worker-bees are large, somewhat feather-colored, very gentle, and scarcely requiring vell or smoke. They stored red clover honey last season.

All queens guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

We would like each of our present readers to have one or more of these fine Queens. Simply send us the name and address of a new subscriber for the American Bee Journal for one year, and 25 cents extra, and the Queen will be mailed to you. Our queen-rearer is now caught up with orders, and expects to be able to mail them hereafter within 48 hours after we receive the order. He is in another State, and we will send him the Queen orders as fast as we get them at this office. He is prepared to rear and mail a large number.

The cash prices of these Queens are $1.00 each; 3 for $2.75; or 6 for $5.00.

Send all orders to

GEORGE W. YORK & CO.,
144 & 146 Erie Street, CHICAGO, ILL.
boil is built over the cell, and this is built downward to make the full size desired. In the meantime the larva has been invisibly fed some grubs. The larva is turned out of the narrower part of the cell. Because such a queen-cell is built from a cell after it has been started as a worker-cell, it is thus amalgamated by a larva, it is called a post-construction cell.

You may not always be able to tell from outside appearance whether a cell is pre-construction or post-construction, but you can always tell by tearing it down and seeing whether it has a smooth conical base, or an angular and sharper base, like a worker cell. A pre-construction cell has an egg deposited in it, never a larva at the start. A post-construction cell is built over a worker-cell containing a larva, although in very rare cases it may contain an egg.

Editor Fout thinks it would be better to call them swimming-cells and emergency-cells. The name emergency-cells is entirely inappropriate, as applied to cells that are built to meet an emergency, and there is just as much appropriateness in the term swimming-cells when such cells are built for swimming. But to use it for cells that are meant for superseding, when there is not the slightest intention of swimming, seems exceedingly inappropriate.

Bees and Alalfa.

The introduction of alfa-flax into Kansas has made the State richer by one million dollars. But the discovery that the honey-bee can feed on alfa-flax blossoms has added another million. Bees and alfa-flax are an ideal combination. Experiments have been made by thousands of beekeepers and they report most favorably upon the blossoms of the alfa-flax.

Alfa-flax contains a certain degree of sweetness not found in either the sweet clover or white clover. Every stock-bred beekeeper that in-and-out in breeding will cause a deterioration in the honey that he produces. He is therefore in a position to give a new life and vigor to the breed. As it is with animals so it is with bees. A bee will produce honey that is as refined as it is to be by feeding the beekeeper a crop of alfalfa.

Bee-keepers can purchase this crop of alfalfa by buying the sugar, which is made from it. It is a sugar that is much more expensive than the sugar made from clover. The sugar, however, is the best that can be obtained in the United States. It is made by the bee-keepers, who do not have to pay for the sugar, as they do when they buy it from the sugar-refiners.

The price of this sugar is $1.25 per pound, and it is sent to the beekeeper in a large box, which is returned to the sugar-refiner. The sugar is then sold to the beekeeper at a lower price than the sugar that is made from clover.

21st—31st

HONEY AND BEESWAX MARKET QUOTATIONS.

CHICAGO, Aug. 22.—White comb brings 15c per pound, for the season, while clover honey does not grading No. 1 selling at 10c14c; light amber, 12c13c; dark, 10c12c. Extracted, fair degree for spot cash, sugar feed at 11c; white clover at 9c10c. Fancy white comb honey sells at 13c14c.

C. W. WEBER.

BOSTON, Aug. 19.—Our market to-day is about the same as last week, with prices for additional material greatly reduced. Several lots of new Vermont honey in cartons has thus far been received, at a ready sale at 17c, although of course in a small way. Extracted, fall supply, light demand.

BLAKE, SCOTT & LEE.

ALBANY, N. Y., Aug. 20.—We quote: Fancy white comb, 10c11c; No. 1, 15c16c; No. 2, 13c14c. Extracted, 10c12c; mixed, 6c8c.

OAHU, Aug. 8.—New comb honey is arriving by steamer in small quantities from Iowa and Colorado, and selling at 20c to 25c a case retail. California extracted honey is being offered cartons at 45c to 48c per box at the California shipping points, but we have not heard of sales having been made. The production of extracted honey seems to be quite large this year in Colorado, Utah and California.

CHICAGO, Aug. 7.—There is some demand for new crop of comb honey, and receipts are quite disappointing (1c to 1.5c a pound). It would appear that they have been principally from the South, but we have not heard of any shipments from New York State and near-by. We quote: Fancy white, 15c; No. 1 white, 13c14c; amber, 11c12c. New harvest is the nearest, and at this time we do not expect any before next month. Extracted is decided dull. Honey traders, with only a limited demand, and quotations are rather nominal. We are selling at from 30c, according to quality, and branding at from 35c per gallon. Beeswax dull and declining; for the week, 2c.

BRETHREN & SOEKOL.

DE LA MOYNE, Aug. 7.—There is very little buying here in new crop of honey. Some small quantities by production are finding their way to market and selling in a retail way at 50c to 52c a case. We do not look for much of a demand in this line before Sept. 1. Our market does not consume a great deal of honey and we sell only of new as yet.

PECKY BROK & CHACE.

DRENT, Aug. 12.—Fancy white comb honey, 14c15c; No. 1, 13c14c; no dark to quote. Extracted, white, 60c80c; light amber, 50c55c; amber, 42c45c. Beeswax, 50c80c.

BUFFALO, Aug. 10.—Quite a good demand for fancy honey, 10c14c, and lower grades, 12c16c in fair demand. Advise moderate orders, as there is only new as yet.

M. H. HUNT & SON.

SAN FRANCISCO, Aug. 14.—White comb, 11c12c cents; amber, 80c1lc; dark, 60c70c. Extracted, white, 55c65c; light amber, 45c55c; amber, 40c45c. Beeswax, 25c50c.

Ripon, Aug. 8.—Comb honey seems to be in plentiful supply, as a rule, unwilling to unload at prices generally lower by wholesale operations. Prices represent as nearly as possible the values prevailing at this date for round lots, although free sales continue. The market is large for both buyers and sellers, while, on the other hand, higher prices than quoted seem to be realized in the selling of some small orders.

KANSAS CITY, Aug. 6.—Some very fine Missouri honey is available for immence selling at 10c11c per pound for fancy white comb honey. Colorado and Utah shippers are offering new comb honey at 10c per pound for delivery, and No. 1 extracted at 8c per pound for No. 1, and 7c4c for No. 2. We quote $1.75 to $1.80 for Fancy white comb honey. Extracted is honey as yet rather unsettled, asking prices from $1.25 to $1.40, f.o.b. shipping point. Hayers, however, seem to be in a hurry to make contracts.

THE
Bee-Keeper's Guide
Or, Manual of the Apiary,
—By—
PROF. A. J. COOK.
460 Pages—18th (1899) Edition—18th Thou-
sand—$1.25 postpaid.
A description of the book here is quite unnec-
essary—it is simply the most complete scientific
and practical bee-book published to-day. Fully
illustrated, and written in the most fasci-
ating style. The author is also too well-known to
the whole bee-world to require any introduction.
No bee-keeper is fully equipped, or his library
complete, without THE BEE-KEEPERS' GUIDE.
This 18th and latest edition of Prof. Cook's
magnificent book of 460 pages, in neat and sub-
stantial cloth binding, we propose to give
away to our present subscribers, for the work of get-
ing NEW subscribers for the American Bee
Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT sub-
scribers only, and a premium is also given to
the TWO NEW subscribers—simply the Bee Jour-
nal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee
Journal (with $2.00), and we will mail you a copy
of Prof. Cook's book FREE, as a premium.
Prof. Cook's book alone sent for $1.25, or we
clinch it with the Bee Journal for a year—both
for only $1.75. But surely any-body can get only TWO
NEW SUBSCRIBERS to the Bee Journal for a year,
and thus get the book as a premium. Let every
body try for it. WILL YOU HAVE ONE?

Send name for our Catalog, Samples of Foundation and Veil Material.

ANOTHER ENDORSEMENT FOR
Root's Red Clover Queens

ALEXANDRIA, IND., Aug. 1, 1901.
The A. I. Root Co., Medina, Ohio.

Dear Friends:—The tested clover queen came in good condi-
tion and has filled seven frames with brood two weeks from
the day she arrived, which is better than the combined efforts of three
"yellow" queens purchased two years ago. I believe she is going
to be the counterpart of the queen purchased of you in 1896, in
which case money could not buy her.

Yours Fraternally,
Evan E. Edwards.

Weekly Budget.

Two More on the 1000.—We have two more names to report before the Buffalo convention, which meets next week. We hope the membership will reach the 1000 mark very soon. We have tried to do something toward raising the number to that figure during the past two months. We will not feel that it is our fault if the desired number is not secured within the time mentioned. We still believe that every bee-keeper ought to be a member of the National Association, which has done such excellent work for the benefit of bee-keeping.

The two names to be reported are these:

Chas. E. Kemp, A. J. Stratton,

Buffalo Convention Lodging.—Secretary Mason writes us that he can secure for such, who desire, “a good, nice, clean place to sleep and get your breakfast at Buffalo for 75 cents.” He says he can get such places for about 60, if they will apply to him at the convention. If more places are needed, The Dr. Pierce’s Free Bureau of Information, at 652 Main Street, will furnish them in such style and at such prices as will be satisfactory, provided they will call for Sydney S. Nepper, for arrangements have been made to accommodate all on reasonable and satisfactory terms, provided the applicant is not unreasonable in his demands; and the information furnished will be free to all convention members.

The Apiary of Mr. H. S. Ferry, of Westchester Co., N. Y., appears on our first page this week. At least a portion of one is shown, which gives a pretty good idea of how Mr. Ferry has his neat bee-yards arranged. The surroundings can not be appreciated unless one visits the yard including his home were given. His house is one of the finest in the city where he lives, and to protect his property he bought 100x100 feet running from the rear of his house lot to another avenue, and this he has for lawns and apiary. The small, long building seen in the rear is a bee-house with doors in front and rear, which opens as a shade in summer. This is for queen-rearing, etc., as well as honey.

The photograph was taken by Miss Mary E. Bickmore, who is a teacher in the High School in New York City. Bee-culture comes in her line. Mr. Ferry has an observation hive, which is used in schools before the classes.

Daniel Wurth’s long-tongued five-banded queens—you can hardly afford to let this season pass without trying a few of them. See his advertisement on another page of this number.

Dr. A. B. Mason, secretary of the National Bee-Keepers’ Association, has declined to act as judge of the aparian exhibit at the Ohio State Fair, on account of the Fair being opened on Sunday. That is the kind of a stand to take. Some Fair managers need to be taught a lesson, and the Doctor has had the courage of his convictions, and let the Ohio Fair managers know that he doesn’t countenance Sunday desecration. He will have no part or lot with them. Fairs or expositions that can’t succeed without opening on Sunday better “die a-borning.”

The Nickel Plate railroad is the one over which Dr. C. C. Miller and the editor of the American Bee Journal will go. The latter expects to leave on Friday evening, Sept. 6, and spend the following Sunday with his mother, about 50 miles south of Cleveland. Dr. Miller will likely leave Chicago Monday, Sept. 9. Mrs. Miller and Mrs. York expect to accompany their respective partners—to keep them straight.
The Buffalo Convention—next week, beginning Tuesday evening, Sept. 10.

Place—Lecture Room of the Buffalo Library Building, corner of Washington and Clinton Streets.

Question—Will you be there?

Rearing Queens for One’s Own Use is the subject of an article in the American Bee-Keeper. The first thing to select are two best queens, one to rear queens from, the other for drones. He greatly prefers the Alley plan for starting cells, not only because it requires less labor, but because there is more danger of getting inferior queens by the Do-something plan. He gives no reasons in support of this latter view, and it would be nothing strange if he should be asked for something more than a mere assertion.

As to the simplicity of the Alley plan, however, there can hardly be question. One who would make a bungling job of forming cell-cups and transferring larvae might easily succeed by the Alley plan, which in brief is as follows:

Take a piece of comb containing eggs; shave away half the depth of the cells on one side; cut it into strips of one row of cells each; twist the head of a match in every alternate cell so as to destroy the egg on the shaved side; then dip into melted wax the other side, and fasten it upon the lower edge of a half-depth comb, the edge of the comb being cut rounding so the cells will not be built too close together; and it is ready to be given to the queenless bees.

Honey and Beeswax Market.—The following is offered by Mr. Stoughton Cooley, one who has read this paper for some years:

Editorial American Bee Journal:

Editorial American Bee Journal:—

Permit me to offer a criticism of one feature of your very good paper. The general excellence of the paper is such that I would not offer this but for the fact that the fault can be easily corrected.

In the column headed "Honey and Beeswax—Market Quotations," you publish quotations of various dates. In the issue of Aug. 8 appear quotations from Chicago, July 18; Cincinnati, May 17; Boston, June 29; Omaha, May 1; New York, July 5; and so on, winding up with San Francisco, June 16. The criticism I offer is that these quotations should be kept nearer current quotations, and should be placed in the market source if possible. For instance, the Chicago market has a regular trade bulletin quoting the prices of honey and wax as sold on South Water Street from day to day. A glance at this paper would enable you to get prices from a disinterested source, and, if you so wished, on the very day you go to press. The other large cities issue similar trade bulletins, and if they would not exchange with you, a single copy a week would surely not cost much.

We wish to thank Mr. Cooley for his suggestion. For some time we have been in the habit of sending out return postal cards every two weeks to those quoting the markets for this paper, and if the report was not changed it was evidence that there had been no change in the market prices for that particular city.

The hint that interested dealers might not furnish as reliable quotations as others, doesn’t appeal to our idea of the matter. As practically all who quote in our market column are commission men, it would seem that it would be to their interest to quote as high prices as can be secured, for the more they get for the honey the more will their commission amount to.

Again, those who make a specialty of selling honey, ought to be able to secure higher prices than other firms, as they naturally must have a line of customers developed who depend upon them for their honey supply.

The trade bulletin suggestion may be well to investigate. We will do so, and see what the Chicago bulletin has to say about the honey and beeswax market. If as good, or better, service can be secured for beekeepers in that way, we must have it, as nothing is too good for our subscribers.

We hope our readers will feel free to offer any further suggestions or criticisms they may think valuable. When presented as courteous a manner as Mr. Cooley has done, they will be welcomed, and acted upon favorably if deemed advisable.

Robbers and Thieves among bees are perhaps generally considered as one and the same thing. W. W. McNeal, in the American Bee-Keeper, calls attention to the fact that they differ greatly, and it is probably true that few beekeepers suspect the existence of thieves among bees. A robber is one which enters a hive and takes honey by force; a thief takes it by stealth. Robbers prey upon the weaker and queenless colonies, being more especially troublesome in times of scarcity; thieves find their best foraging ground in the hives of strong colonies at a time when honey is coming in a flood. There seems to be no way to circumvent this quiet stealing. The practical point in the matter is the danger of giving credit to a colony for extra-storing ability when that storing comes from thieving and then breeding from such stock. Some times a colony is found storing when other colonies must be fed: and Editor Hill suggests that it would be a good thing to compare the honey stored by such a colony with the feed given to the others, to see if it might not be the same.

Keeping Over Extra Queens from one season to another, Editor Root thinks, can only be successful by keeping the queens in nuclei in a good cellar.

Pasteboard on Queen-Cages has been in use for some time, the object of the pasteboard being to delay the bees getting at the candy to release the queen. But it has been found that sometimes the bees fail to gnaw the card, and so the queen is not released. The A. I. Root Co., who originated the pasteboard plan, now instruct to tear off the pasteboard in 24 hours, if not already removed by the bees.

Fumigating Section Honey is insisted upon as absolutely essential by some, while others say it is not at all necessary. One thing upon which there can be no disagreement is that it will not do to put upon the market section honey with waxers in it. It is possible that the difference in bees has something to do with the difference in experience. A good strain of Italians or hybrids may keep the combs so clean of worms that fumigation may not be necessary. Close watch should be kept by the novice to see whether there be any evidence of worms in the way of a white powder on the edge of the unsealed cells, especially on the bottom part of the section close to the wood. When anything of this kind is to be seen, fumigation should be resorted to at once.

The common plan is to use sulphur, which easily destroys the young larve, but is less effective against those of larger growth, while it makes no impression at all upon eggs. This makes it necessary to fumigate at a second time. Some are enthusiastic as to the use of bisulphide of carbon in preference to sulphur, claiming that it kills eggs as well as larvae. So the sections can be fumigated as soon as taken from the bees, or as soon thereafter as may be convenient or desirable, and no further attention will be needed. Another advantage claimed for the bisulphide of carbon is that it does not dissolve the sections, while too much sulphur will give a coating of green. But care must be taken to avoid having a light come near the bisulphide, as it is very explosive.
The Art of Bottling and Selling Honey.

BY J. C. WALLENMEYER

HAVING had an experience of eight years in bottling a
dozen different kinds of honey in a dozen different
kinds of packages or containers, I thought I would
give the benefit of my somewhat varied experience to the
readers, that they might possibly profit by avoiding the
usual mistakes of beginners in using unsalable packages.

I have bottled honey from alfalfa, basswood, willow-
herb, white clover, California sage, Florida mango, saw
and cabbage palmetto, wild aster, and smartweed (or hearts-
order) mixed; dry-weather honey-vine, and fall flowers.

For containers I have used pint and quart Masons, costing
50 and 60 cents per dozen; 6 and 8 oz., and 1 and 2
pound square flint-glass jars, costing $2.70 and $2.50 per
gross (corks included); 13 and 16 oz. jelly-glasses; ½-gallon
fruit-tablet jars costing 5 cents each; lard-buckets; glass
bowls, and Root's No. 25 round flint-glass one-pound jars—
quite a variety to select from.

I found Root's No. 25 jar the best and quickest seller of
all, because, after being emptied, it could be used as a self-
sealer for jelly, preserves, jams, etc.; only flint-glass jars
should be used, as they show the honey off to perfection.
Amber honey will sell nearly as well in quart Masons on
account of the universal use of the package; but it is hard
to sell 3 pounds of honey to every-day consumers. Most
people prefer a small, cheap package. Our market demands
a honey of light or light amber color, heavy body, mild
flavor, and fine bouquet or aroma. It does not pay to bottle
a poor grade of honey. The people generally get accus-
tioned to the kind of honey produced in their own locality.
I found this out to my sorrow when I tried to sell three bar-
rels of mangrove and palmetto honey from Florida,
although I thought it fine indeed. This matter of selection
is very important. If you happen to run short of honey,
and must buy, procure an article as near like your own as
possible. I have found that patrons grow suspicious when
they get different honey. I find honey from white clover,
dry-weather honey-vine, and fall flowers, to give the best
satisfaction for bottling, in my locality.

Williamson Co., Tex.
Briefly stated, there are three essentials for success in bottling honey:
1. Best quality of well-ripened honey.
2. Neat attractive packages, useful when empty.
3. Aggressive selling methods.

You might have the very finest honey, but if it is not put up attractively, it will not sell. You may, however, get up a neat attractive, gayly labeled package, but no one will buy a second time. Again, you may have a fine article of heavy body and fine flavor, put up in the right kind of package; but if you are not aggressive, why will it sell? Aggressive selling tactics, of course: be aggressive; talk honey everywhere you go. I built up an enormous trade in the fall of 1894 with a well-ripened crop of honey from dry-weather vine and fall flowers. I controlled that time of year, to a large extent, by the dray trade in Evansville, and probably half of the grocery trade. I bought 5 barrels of Root's No. 25 1-pound jars, and one gross each of the 8-oz. and 8-oz. square flint Muth jars, and from this stock of 2-pound Muth jars, all at one time. I had every kind of package to please the most fastidious. I sold both the 1-pound square and round jars at $2.00 per dozen, to retail at 20 cents. The 5 barrels of Root's No. 25 bar were gone in a jiffy, while I have nearly all the 5 and 8 oz. jars yet. These I use at fairs to give away as samples. I often sold a dozen of the round jars to housewives who wanted a set for jelly, etc., but never sold more than one big jar or so of the square jars at one time to any lady. They are considered worthless when empty, although my wife likes them for small pickles and catsup. I use the No. 50 label, costing 1 cent per 1000, for both round and square 1-pound jars. This label is showy, and will not soil easily in fly-time. I find the 2-pound square jar an easy seller to parties who mix their own cough medicine ever so mildly.

I have now dwelt at length on the merits of various packages, as I think it a very important item to help sell our honey. I forgot to say my worst-selling package was the tin lard-bucket, Mr. R. C. Aikin notwithstanding. They might be all right to sell to old customers, but the main objection is that people can not see the contents unless it is opened. To get new customers to buy your honey, invest 5 cents in a "glass show-case." As honey is poured into these, you construct the grocer to place conspicuously, and you will have the pleasure of selling both "show-case" and honey at the same time.

HOW TO LIQUEFY; HOW TO WASH THE BOTTLES.

We will now proceed to the process of bottling. Have your honey liquefied, if candied, holding the same at 150 degrees for two or three hours. By using a gasoline stove you can regulate to a degree, almost. Be sure not to overheat, as this is troublesome in 180 or 185 degrees; but I prefer not to risk losing the aroma and injuring the delicate flavor. If you are compelled to buy honey, always buy in 60-pound tin cans, as they are more convenient to handle. While you are liquefying your honey, wash your bottles, using clear, soft water with sal-soda, and shoot to remove dirt and particles of glass if new. Then rinse in clear water, and place bottom upward in racks to drain. This will make flint jars clear and sparkling. I did use a ten-gallon filling-can, bought of Mr. Muth, but now prefer to use my extractor (with cross-arm and basket removed), raised to a convenient height. I prefer to bottle honey hot, as it runs quicker, retains its aroma, and will stay liquefied much longer.

Have the rack containing empty jars at your left. Place the pan under the honey-gun to catch any drippings. You will soon learn how to cut off the flow just right the first time. Pass the jar to an assistant at the right, who presses the cork (cost 75 cents per gross) in the mouth, then dips the jar into melted wax and paraffine, half of each. A second assistant puts on the tinfoil (costs 75 cents per gross) in place; winds a capping-strip around the jar with the tinfoil, and then holds the jar in the left hand, running the head up and down on the strap until the cap is nicely smoothed down. A pasteboard, about 12x20, covered with dextrine (costs ten cents per pound), is covered with another pasteboard, and the operation is repeated. While the jar down flat, deftly catches the label by the corner, removes it from the board, attaches it to the center of the jar, smoothing it out with a soft cloth; then she places the jar in the case at the right, holding a dozen each.

After a little practice, three persons can easily fill, cork, wax, tinfoil, label, and pack 800 pounds a day, and not spill a drop of honey, by this method. The corks used for honey-jars are seconds, and ought to be covered with wax to effect an air-tight sealing while the honey is hot.

HOW TO SELL THE BOTTLED GOODS.

Now, then, we are ready to sell. Tug on a bit; for if you will notice you will see that all successful sales are well dressed and well groomed. Take a sample jar of each kind, and go to your grocer. If he is busy, see if he has any honey in sight. Don't attempt to sell to him while he is busy. If he is not, tell him you have a fine article of honey, fine flavor, and good body; that the crop of honey is very short this year, and you will not have very much to sell. If you tell him you have five tons he will expect to get it for nothing. Hold your jar to the light; turn it upside down to see how thick it is; talk honey, talk business, and stick right to him. Have one price for everybody. It will pay you to allow a good margin of profit, and he will then try to make more sales than if he made a very small percent of profit. But be sure to have your honey placed where every one can see it on entering the store, as people hardly ever ask for honey unless they see it. Remember, in conclusion, that he who tooteth not his own horn, the same shall not be totaled.

LIQUEFYING-APPARATUS—SEE FIG. 1.

In presenting a photo of my liquefyng-apparatus I have tried to make it conform as nearly as possible to the requirements of the average bee-keeper. Although I usually liquefy on a gasoline range, the cut shows 500 pounds of candied honey liquefying, without interfering with the preparation of meals. Two 60-pound cans are placed in two common wash-boilers, then filled with water, and heated gradually. After all the honey in the can is liquefied it is drawn off into an extractor-can (with the baskets and crank removed), by means of a rubber hose, the can being covered to prevent foreign substances lodging therein. I had a Muth ten-gallon filling-can, but I like the extractor better, as it has a much larger honey-gate, which is very essential in rapid filling. If the honey is cold, the flow can not be cut off a third as fast; therefore with honey at about 140 to 150 degrees Fahr., and a large honey-gate, we attain the maximum of rapidity in filling. Besides, I found, at least in my experience, that, in filling with cold honey, a large number of air-bubbles formed, thus preventing our getting the desired amount in the bottles. It would also run over the sides when heated to the right degree. Of course, no one would attempt to seal until the
bubbles had risen to the surface, which they will do in a few minutes with hot honey. If the honey is then sealed, and either dipped or corks sunk, and any kind of good sealing wax applied, and hermetically sealed, the honey contracts when it gets cold, thus causing the much-talked-of vacuum, especially if a tinfoil cap is properly applied, making it absolutely air-tight.

I found, only the other day [February], 2-pound Muth jars which had been waxed, that candided, while others on the same shelf, sold to the grocer the same day (Oct. 5, 1900), were nice and clear on account of the tinfoil cap. I find that if, after sealing, the jars are left in a warm room, thus preventing the too sudden cooling of the wax on the corks, we shall have no cracks. If one-half paraffine is added to the wax it will not crack nearly as easily, besides being much cheaper.

**WASHING THE BOTTLES WITH SHOT.**

In regard to the washing of bottles, I had a good laugh over the little boy punching the little pieces of glass out of the bottles, especially new ones. I used to do the same thing. But how much nicer, and far more easy, and quicker, to take about 3 or 4 oz. of No. 6 shot, and the bottle half full of warm soft water! Few shakes, turn the bottle, then pass to helper, who rinses in clean cold water, and we have a clear sparkling jar which is then set upside down in a large tray to drain.

If using jars like the No. 25 and the No. 100, where it is impossible to get the top with wax, I now pour into each a large tablespoonful of beeswax and paraffine, right on top of the heated honey, which, when cooled, effects the air-tight sealing. This is an additional inducement to my patrons, who, I know, see a nice piece of wax to slick up their iron's for laundry work; while, if put on the cork, it prevents the cork from breaking to pieces while being drawn out the first time.

If I am compelled to reliquify any bottles of honey (whew! here's always got left jars by the combs melting, the honey drooping many bees and causing them to be robbed. I have heard of no other loss in the country, and some of the best bee-men have told me it was for the want of water.

I would say in conclusion to those readers who have no honey to bottle, better order a few cans of extracted, and a barrel of the No. 100 or No. 25 jars, and canvass your nearest town. You will be surprised how easy it is to sell a barrel put up in this neat, useful, and attractive package. It pays to work up a trade in a bad season, for, if you sell no honey in a season, you can make notes you expect to sell three or four tons when you have not previously worked up a foundation for the disposal of your coming crop?—Gleanings in Bee Culture.

**Do Bees Use Water to Cool the Hive?**

BY J. A. GERELD.

JULY 6 was the hot day in Uvalde County, Texas—106 degrees in the shade—and I had a heavy loss of bees on that day by the combs melting, the honey drooping many bees and causing them to be robbed. I have heard of no other loss in the country, and some of the best bee-men have told me it was for the want of water.

I would like to state the particulars of the case in the American Bee Journal, and have the opinion of others on the subject.

I had been running about 200 colonies in one yard until last winter, when I concluded they would do better divided into two apilaries, so, finding a suitable location about 2 miles from the old yard, I cleared the brush off of a piece of ground 150x200 feet. The brush is thick all around, and six or eight feet high. I drilled a well and found water. Then I moved 100 colonies and placed them in two rows, seven feet apart, running north and south along the east side of the clearing, up close to the brush, leaving a space near the middle of the rows for a honey-house. I built the house so that I can pass through it with the wheelbarrow, and all the time be in between the rows of hives and at the back end of them, as one row fronts east and one west.

The hives are of the lock-corner 10-frame style, some having flat and some gable covers; 70 colonies are on the north of the honey-house and 30 on the south, and 60 of the 70 melted, and I lost 30 of them, while only eight fell of the 30, and I lost four of them, making a loss of 40 colonies, except that I hived the largest swarm I ever saw.

Most of the summer breeze here is from the southeast, so the brush and honey-house kept it from the ones north of the house.

I watered the bees in the yard by letting the water drip from a barrel into a flat trough. The barrel would take about two days to leak dry. I left the apilary July 2, to spend the “4th” in town; I know the bees would be out of water before I returned, but thought it would make no difference, as they had nothing else to do but carry water from the old apiary, which is about 1½ miles on a line from the new one.

I returned July 8, to see a sight I had never dreamed of seeing; the trouble was easily seen. I walked into the honey-house, lit the smoker and put on my veil, and then took a good look before venturing out. The air was so full of bees I could hardly see across the yard. I expected they would drive me off the place, but I stepped out and walked boldly along between the rows. Looking over in front I could see where the little lakes of honey had been the day before. I began to count the wet spots in front, but when I counted ten in succession I concluded all was lost. I looked all about, not knowing what to do. Well, what could I do? To my surprise, the bees offered no objections to my presence, in fact, they did not seem to know I was there. There was a great honey-flow on, and they did not care what I did with them. But what could I do but let them alone?

I looked into four or five hives where the most bees were going in and out; they were so nearly cleaned out that I let them finish the job. Near by I saw about an ordinary wash-tub full of bees settled on a bush near the ground. I thought to hve them, but I went at it just as in swarming-time, only I prepared three boxes instead of one. I put nine combs each in two of them, and an empty one on top for air, and room. They hived nicely. I shaded them well, and left them until the next day, when I gave them about ten pounds of honey in the top box. They seem to be contented now (July 27). That was all I did in that yard for 10 days, when I started in to do my part of the cleaning up.

I was surprised to find honey in some of the robbed

---

**FIG. 3.—LABELING AND TINFOILING WITH A CAPPING STRAP (TINFOILING SHOWN AT LEFT).**
ones, and no bees about them. I could look into the hives with the air in without smoke or veil, leave the top off, and other bees would not go about them. What was the matter? Were they tired, ashamed of themselves, or disgusted with the size of the job? Even now (30 days after) they would see the bees rob in a healthy yard. I think because the weather is so dry and hot. There hasn’t been a blossom of any kind for nearly two months.

The hives in the old apiary are the same as in the new one—arranged in the same way, two rows running north and south, and in front of the house. In the north end of the rows, with a clean, open ground south and east of them; but no comb melted that I know of.

Now will G. M. Doolittle, Dr. C. C. Miller, Prof. Cook or any others, tell me if the result would have been different had the bees in the new yard been supplied with water July 10th. It was the first time that any hives were taken from the old apiary; they knew where it was. I think the surroundings had more to do with it than the water.

Uvalde Co., Tex., July 27.

The In-breeding of Bees.

BY GEO. SHIBER.

NOTICING the editorial on page 355 on the subject of in-breeding, and also having read in the other bee journals what has been printed on the same subject, prompts me to add a word on the subject.

I have wondered in the years past, since I have been interested in bees, that it has never received consideration by bee-keeping writers, I suppose, has not, for I have never read anything of it until lately.

For instance, a leading queen-breeders advertised, a year or so ago, that his drones were not akin to his queen-mothers; that new, selected stock was added from time to time to furnish drones. You see, he was constantly selecting choice queen-mothers, and selecting choice drone-mothers, but not akin. A breeder can make some progress in this way, but it seems to me it’s mighty uncertain. Breeding for the breed, and to breed the same breed, coming in contact (though of the same breed) produce a stock that tends to stamp out the desirable quality—the bloods do not harmonize where coming in contact.

I have a rule to follow. The bees, queens whose bees are long-tongue, (admitting for argument’s sake that long tongues increase the honey crop); choose one for drone-mother, the other for queen-mother. Now, when the queens and drones meet, there will be some that will be as good as their parents, but I should think not a few. Further, if the standpoint of other stock breeders, it would be making progress backward. I would give twice as much for queens reared from a long-tongue mother, and have said queens mated to her sons. Further, if the stock were reared by good bee-keepers, their parents, some would be better, sure—no doubt about that.

Perhaps my bee-keeping friends will think I am speculating too much. Not at all.

Let me call your attention to another kind of stock that I have bred for years as a sort of hobby. I refer to homing pigeons. The great aim with these ”couriers of the air” is to breed for speed and long distance. A bird that can fly 500 miles a day is a prize. Do they in-breed? Well, yes! Father and son, brother and sister, grandfather and granddaughter, and so on. Are they weak and scrawny from such in-breeding? Pick up a bird of mine from Maryland, which flies 500 miles a day, start him from home, Md., a distance of over 250 miles, air line to the home loft here; released at 9 a.m., he was back in the loft (home) at 4 p.m. Some days, when he is picked up he feels hard—“hard as nails,” as the fanciers say. How was he bred? Why, from a brother and sister. Mind you, this is a hard fly, as he had to come over the Allegheny mountains, diagonally across the State of Pennsylvania. Most of the leading pigeon fliers in-breed; of course this can not be carried over too far, or rather we breed, it is a fine breed.

In-breeding, you see, tends to harmonize and intensify the two bloods. It is an old saying, if you in-breed stock it will soon decline and weaken. It is no doubt true; but the breeder unmercifully suffers his stock. Say one season breed drones and queens together from the same mother; the next season use the same mother for queens. For drones use one of her daughters; she mated to good stock in a different yard. Then her daughter mated to a drone from the first mother of the previous year. Then you have a small fraction of new blood added, that will tend to give your stock added vigor, and will not affect the desirable qualities of the strain you are building.

I am aware of the fact that this mating of queens is hard to control, but the only thing that can be done is to make the effort towards that end, until mating of queens in confinement is an assured fact. But not much headway will be gained by the “direct cross” spoken of by some breeders. Why, if they were not for in-breeding we never would have had White Leghorn, Plymouth Rock, Wyandotte hens, or other breeds of “made” stock, so well known by everybody. Take the Buff Leghorn—a new breed which was produced by in-breeding, and selection and in-breeding. There are hundreds of other illustrations.

I think this matter would best be left to queen-breeders. I have—and I suppose others have—a dozen or more different strains of Italian blood, in my apiary, but I expect to make more of an effort to rear drones from the same mother I rear queens from.

Cattaragus Co., N. Y.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, 111.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Keeping Chickens from Bees—Italians.

1. I have some bees about four rods from the chicken-house. If I clip the queens’ wings, would the chickens eat them, when they swarm? They walk around the hive a good deal. I would like to know.

2. If I can’t do this, what other method would you advise, to keep swarms from going away?

3. My bees have five yellow bands on them, but to stand far away and look at them they look pretty black. What kind do you think they are?

MINNESOTA.

ANSWERS.—1. It is not likely that there would be any trouble.

2. If you should find that the queens were endangered by the chickens, it would be an easy thing to fence the chickens out from the bees, or rather to fence in the bees from the chickens. A fence around the bees, of poultry netting 18 inches high, over which you could easily step, would fence the chickens out. You cannot fence chickens in with such fences, they will just fly under, or crawl. There is always a little flowery beds, and not a chicken would cross it.

3. However dark they may look, the five yellow bands indicate Italian blood.

Two Ways of Putting on Supers.

There are two methods of manipulating supers during a honey flow in common use, as follows:

First, by raising the supers when partially filled with comb honey, and putting the empty super underneath and directly upon the brood-chamber.

Second, by placing the empty supers on top of the partial supersed super or supersed, with additional sections needed.

Which of the above methods do you use? and why?

“OUT WEST.”

ANSWER.—Both. When a strong flow is on and there is every reason to expect it will continue as long as the first is half filled. If the bees seem crowded for room it may be given the first super is half filled. It is put under the first super, because that will obligate the bees to occupy it promptly, for they can not enter the upper without at least passing through the empty one. If the room seems still to be needed, a third super may be given before either of the first two are finished, and I have had as high as five or six on at a time, and not one of them finished, the last one put on always being the lowest. But it is a risky business to have so many unfinished sections on at a time, for if the flow suddenly stops,
there you are, with the cold chills running down your back at the thought of a big lot of honey on the hives and none of it in marketable condition. If, however, the flow will be accommodating enough to continue till all are finished, there may be decided gains in having on so many sections, for the bees will have more room to work, and will do the better for it. But never get on so many at a time that all will not be crowded with bees. On the other hand, there is a loss of two or three supers because the bees are enough to crowd two or three supers and only one is on.

Toward the close of the harvest, or at any time when it is doubtful about much more being done, it is often difficult to decide whether or not a supers should be given or not. At such times it is better to put the empty supers on top, for the bees will not crowd up into it unless they really need it.

**A Glucose Question.**

Among other ideas I have had this one: that one reason why bee-keepers oppose the use of glucose is that it is unwholesome, if not injurious, as an article of food.

Dr. Howard Miller, editor of The Inglenskoy, says in the June 15th issue of his magazine, in answer to the question, "Is glucose unhealthy?" asked by one of his readers:

"No, I think it is. It is not as sweet as the sugar it usually takes the place of."

Now, as the editor of The Inglenskoy is pre-eminent a scholar, and you are in addition a practical bee-keeper, and have reason to be thoroughly acquainted with all the properties of glucose, I would like very much to know what you consider it. MISSOURI.

**Answer.—**Chimically pure glucose is one thing, and the commercial article quite another. However correct the scholarly editor may be in thinking that chimically pure glucose is a wholesome article of diet, if he should get a swast of some supers of commercial article, he would be likely, after vainly trying to get the taste out of his mouth, to decide that it was neither fit for man nor bee.

**An Amateur's Bunch of Questions.**

1. When the honey-flow is plentiful, why do some apiarists place two, and often super between the brood-chamber and a filled super?

2. I have my colonies on treestils, made of 2x3 stuff nailed together in stretcher form, with legs nailed so the hives are about 12 inches from the ground, placing three colonies in a group. What objections is there to this plan? Why?

3. I use a common white table-cloth with smooth or glazed surface on top of sections as a sort of cover or blanket. Do you think this has been used before? What objections can be offered to such use? Why?

4. Does the queen ever leave the hive except at swarming-time?

5. When (at what age) does the virgin queen leave the hive, and how long from the time she mates does she produce eggs?

6. Why do we find more drones in some colonies than in others, although apparently about equal in numbers?

7. Is it possible that a colony will carry over one or more drones during winter?

8. If two colonies with brood-chambers well filled with honey, and supers containing sections with starters, were given 50 pounds of extracted honey, how much would be stored in the sections?

9. How can honey be made more liquid, or thinner, or gravity lessened?

10. What is honey-dew? INDIANA.

**Answers.—**To give room for the bees to store more honey, I think this is possible, perhaps you mean to ask why they put the empty super under the one partly filled instead of putting it over. Because the bees will begin work in it sooner if the empty super is under instead of over; and because the bees in a filled super may be wrapped a little whiter when raised up. Perhaps, however, you mean to ask why the empty super is put on at all before the other is finished and taken off. Because after the sections are all filled the bees take some time to finish up the sealing at the outer parts, and it would be a waste of time to wait till the first super can be taken off.

2. In the height of the honey-flow the bees often fail to the ground in front of the hive as they come from the fields heavily laden, and they must rest quite a little time before they can rise and fly to the entrance. With the hive on a stand near the ground they can crawl in at once without waiting to fly in.

3. I formerly used enamelled cloth over the sections, and the bees not only prop on it. In the angle where the oil-cloth rested on the sections, but crowded it under the oil-cloth and on the sections. I find the sections less daubed since there is nothing over them but the board cover with a beespace between. There are no other-isms.

4. No, not after she begins laying.

5. She makes her bridal trip when about five to eight days old, and begins laying about three days later.

6. In a colony hives there is little or no drone-cob, so of course few or no drones will be reared, while in other hives a large amount of drone-cob gives opportunity for many drones. A colony with a young queen is not likely to have as many drones as one with an old queen.

7. I don't know. Some say they can get 3, if it in sections, others say not more than 4.

8. Add water to it.

9. The secret of plant or scale lice, and also, according to some authorities, an extra-nectarine secretion of plants without the presence of plant or scale lice.

**Superseding Queens by Rule.**

Procrustes kept a nice lodging-house—leastwise he had an iron bed with chopping-off arrangement and power stretchers attached. Every bodger had to be made to fit the bed, no matter what cost of blood, bone, and grens. Distant cousins of Procrustes are those brethren who supersede every queen at the same exact and early date of her life. She may be good for a month yet, or may be good for three years yet—all he same. Chop goes the Procrustean bed, who knows but what the long legs and winged bees in the country have their line terminated by that chop? Mr. Doolittle's way of giving a protected cell, and letting the bees decide whether they want the young queen or the old one, seems to be much the wiser way. Bees show more practical sagacity in such matters than to most of us seems possible. Page 467.

**PEAR-BLIGHT AND THE BEES.**

It is evidently quite a "peck of bushels" our cause is getting into California about the pear-blight. If the fruit-men not only have assurance that the saint might have stolen the horse, but that testimony that the horse won't let dinners ride him under no circumstances, why then the case begins to look a little dark for the saint. Ernest Root is evidently sound, that there must be more evidence than one scientist as to the impossibility of blight traveling on the wind. The fact that extensive pear orchards which have never bloomed yet are as badly infected as any is a tower of strength to us which we should make the most of. I'll venture the guess that the smallest size of bark-house-eating is nothing of the kind. The infected crack them off from the roots, and leaving some wherever they go in search of little insects. Prof. Cook's opinion, expressed on page 516, is important. He feels sure that there will be plenty of means where arsenic is used after the removal of the bee—and without calling on the wind, either. Leastwise let us not "get off the earth" with any needless haste. Possibly a little silent inertia will do us good—let the other fellow do nine-tenths of the talking, and most of the acting. Perchance most of this is merely a cloud, and it is the tendency of clouds to roll by. Page 468.

**Queen Suppersions and Linden Blood.**

Three-quarters of all supersessions within three weeks of the close of the linden. I wonder how widely that is true in other yards than Mr. Doolittle's. Perhaps there where is no linden the last strong flow of the season would be its equivalent. In my yard I kind of think that more than the remaining one-quarter occur in swarming-time just before the linden. I may be quite wrong—only go by my guess as to how many prime swarms have virgin queens. I suppose the general principle is that when bees are rearing little brood,
The Home Circle.

Conducted by Prof. A. J. Cook, Claremont, Calif.

OUR SOCIAL LIFE.

The Good Book is well named—The Bible—which means "the book." It is the book. The other name—the Gospel—means "good news." And it is good news, indeed. It always advises us rightly and so, of course, wisely. How good to have a friend who can tell you by word of advice, whether the bees are in a body actually do stay put, or whether a large fraction of them return to the old stand. Not unwise to hold the thing as an experiment until many brethren have continued success in making all the bees stay.

The dear, old Bible may be just such a treasured friend to every one. It, like its author, is too wise to err, too good to be unknown. This dear old volume says that he that neglects those of his own household is worse than an infidel. It is suggested that a good friend in the蜜蜂 colony is an old know. Whether or not a social function, if such already exists, will then it will never cease in our love to keep it all to itself. It will so touch life with the spirit of sweet helpfulness that all in the home will reach out to bless and help those of other households.

It was my good fortune to be in Columbus, Ohio, when our beloved and martyred president, James A. Garfield, was elected to the United States Senate. I heard his speech as he responded to the congratulations of his great, good fortune. He said, in short, that it had given him pleasure, when he had so fortunate as to act in a way to meet the approval of his countrymen the country over. It brought a deeper gratification to know that his policies and the interests of his own State and Ohio. He was you more pleased at the applause of those of his own district and were stirred more among the guests of those of his own home—his very neighbors. A still keener relish greeted the approval of the dear ones of his own world—his own home life—when he wholly pleased James A. Garfield. I suppose it is the best satisfaction, when our own consciences say without let or hindrance, "Well done."
To Our Shippers:

We were obliged to notify you a few weeks ago that one Joseph M. McCaul had leased our old quarters at Nos. 120-122 West Broadway, New York City, and had there started up business under the name "Hildreth, McCaul Co.," and had distributed a multitude of circulars so worded as to create the impression that his business was a successor to or a branch of the business of Hildreth & Segelken.

For the protection of our shippers and ourselves, we at once instructed our attorney to commence action to enjoin the said McCaul from using the name HILDRETH in any manner whatsoever in connection with his business. On the 10th day of July, 1901, Hon. David McAdam, Justice of the Supreme Court of the State of New York, after a full argument upon the merits, issued a peremptory injunction, of which the following is an extract:

"And it appearing that the plaintiffs have for a long time been and now are carrying on business under the style of 'Hildreth & Segelken,' and that the defendant has recently opened a business at 120-122 West Broadway, in the Borough of Manhattan, City of New York, and is carrying on the same under the style of 'Hildreth, McCaul Co.,' and that such act is in violation of the plaintiffs' rights, and that the commission or continuance thereof, during the pendency of this action will produce irreparable injury to the plaintiffs; it is

ORDERED that the defendant (Joseph M. McCaul) and each of his agents, servants and employees and all other persons acting under his authority and direction be, and he and they are here-by restrained and enjoined from showing, displaying or otherwise using during the pendency of this action in or upon any papers, devices, sign or signs, or otherwise, in the business conducted by the defendant at No. 120-122 West Broadway, in the Borough of Manhattan, City of New York, or elsewhere the name of "Hildreth" separately or conjunctively with any other name, designation or description."

Outside of our desire in our own interests to protect the name which we have built by years of satisfactory dealings with our customers, we hastened to procure this injunction as soon as possible, to prevent our shippers from being misled into sending their goods to one who would make an attempt to gain their trade by such a trick and device.

With thanks for the many expressions of good-will we have received from our shippers concerning this attempt to trade under our name, we are,

Sincerely yours,

HILDRETH & SEGELEKESKEN,
265-267 Greenwich Street, NEW YORK, N. Y.
Bee-Keeping in British Columbia.

It may interest some of the readers of the American Bee Journal to know I have initiated the successful keeping of bees in this section of the country. I know of no other bee-keeper in this whole district—certainly there are no bee-keepers nearer than 40 miles, that is, at Nelson, and I do not know of any there.

I was told that bees would not do here. A Mr. Powers brought some here a few years ago, and they could not find food, and he assured me I would fail. But I am a man "wonderfully wedded to my own opinions," and my present success is not going to make me have less faith in my own ideas.

I bought a colony of hybrid-Halians in Vancouver last spring, and they have given me three swarms, the first of which is doing remarkably well. They have two supers over a 10-frame Langstroth hive filled with honey already. That means between 60 and 70 pounds of honey for me, and it is 25 cents a section here. The original colony is not doing so well. They will not take to the supers, and appear lazy. Yesterday I tried to stir them to activity by taking a frame of honey from the brood-chamber and replacing it with an empty one.

The other two colonies are doing pretty well, and have their winter supply, but nothing so far for me.

I think that when Mr. Powers first brought bees here there may have been no proper food for bees, but since then the town site has been cleared off, and the white clover is occupying the ground.

While writing this letter I have had a visitor from Nelson, who tells me he has bees there.

The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only $1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey.

This is the famous White Clover Honey gathered in the great Alfalfa regions of the Central West. This honey is extremely rare, and nearly everybody has solved the problem of a successful and pure honey at all can't get enough of the Alfalfa extracted.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 8 cents per pound: four or more cans, 7½ cents per pound. Basswood Honey, ½ cent more per pound than Alfalfa price. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are boxed. This is all ABSOLUTELY PURE HONEY

Read Dr. Miller's Testimony on Alfalfa honey:

I've just sampled the honey you sent, and it's prime. Thank you. I feel that I'm something of a heretic, to sell several thousand pounds of honey of my own production and then buy honey of you for my own use. But however loyal one ought to be to the honey of his own region, there's no denying the fact that for any kind of hot drinks, where one prefers the more wholesome honey to sugar, the very excellent quality of alfalfa honey I have received from you is better suited than the honey of any other marked flavor, according to my taste.

C. C. MILLER.

Order the Above Honey and then Sell it.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money and get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

Farm Wagon Economy.

The economy of this proposition is not all found in the very substantial price of the wagon itself, but in the great amount of labor it will save, and its great durability. The Electric Wagon Co., who make this Electric Handy Wagon and the now famous Electric Wheels, having a certain degree of experience with bees, have over 400 fine Queens, and can fill orders on the same day I receive them. We have five sales a day. This advertisement will not appear again. Remit by post-office money order.

DANIEL WURTH,
Cost Creek, Anderson Co., Tennessee.

[Mr. Wurth is perfectly reliable.—Editor.]

and he is the only bee-keeper in that locality. He beats me, for he has had five swarms from one colony, making six in all, and they are doing well.

I have only to add that he and I are both beginners, and I value highly the hints I get from the American Bee Journal.

British Columbia, July 24.

H. BEER.

The Honey Market In California.

The honey season is ended for this year in this locality. Our honey is in packages, and the most difficult problem for the bee-keeper is upon us—disposing of our honey at a price that will give us honest remuneration for the labor expended and capital invested.

I have heard some say the market is deplorable; I do not consider it so. A demoralized market is one where the product is thrown on the market and sold for what it will bring, and where there are more sellers than buyers.

I am pleased to note that such is not the case in Southern California at present. There is very little honey moving, not because there are no buyers, but because the buyers are not offering what the producers think they are entitled to.

While there is no organization or general understanding amongst bee-keepers, yet there seems to be a general feeling that we ought to have, and will get, 5 cents a pound for this year's crop of extracted honey, and they are almost all living up to their feelings, and holding their honey; and I think if they hold on for 60 days longer they will realize their expectations.

Every little lot that is sold at the price the buyers are offering, the report of that sale is hawked all over the country, and made the most of to scare holders.

J. W. GROUSE.

An Experience and a Question.

I am not one of those lucky bee-keepers who get large yields of honey, yet I get fair yields. I keep a record of every colony, and the date of swarming, etc. My hives are all numbered. If they have prolific queens it is so marked on the book, and those that are extra honey-gatherers are also marked. I started in the spring with nine colonies, and now I have 26, and have taken off 200 pounds of comb honey. I will give the record of one colony, and then ask a question for Dr. Miller to answer:

May 20 I bought a colony of bees in a two-story hive for $2.00. When I got them home I examined them, and found the upper story full of brood. June 10 they cast a swarm; it was very large, and when they had filled it a 10-frame hive apparently full. The hive of this old or parent colony is No. 21. The new swarm was hived in No. 15. In nine days after the first swarm No. 21 cast a second swarm, which was hived in No. 11. About five days after this, when I was absent from home, my son-in-law saw a swarm of bees in flight, but could not discover what hive they came out of. They clustered, and he hived them; it was a very small bunch. There was a space of about six inches between hive No. 15 and No. 11. A day or two after this little swarm was cast, I saw bees going on the alighting-board from No. 11 to 15, and on looking into No. 11 I found some comb, but no bees. On the 18th-24 days after the

The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helpt on the way to success with bees.

The book we mail for $1.25, or club it with the American Bee Journal for one year—both for $1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with $3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

swarm was blived in No. 15—they cast a large swarm, and also had 28 sections nearly full, which they soon finished, and I took it off and gave them 28 empty sections, which they now have nearly filled. The old colony, after casting two swarms, filled the upper story with honey, and I extracted 25 pounds from them. I now have 9 colonies of bees and 64 pounds of honey, and more to take off, from my $2.00. Now here is my question for Dr. Miller: If it takes 21 days from the laying of the egg to mature a bee, and a few days to make comb for a queen to lay in, how do you account for the large amount of bees in No. 15, so that they cast a large swarm in 25 days after being left alone, nearly filling 28 sections; and yet, after casting a swarm they continued to work in the boxes without any apparent loss of bees? The second swarm in No. 11 was almost as large as a prime swarm. Did a part of them swarm out, making the little swarm I have mentioned? If so, what became of the balance? Would they be reduced into No. 15?

S. B. SMITH, Millilacs Co., Minn., Aug. 5.

An Amateur Transfer of Bees.

Having purchased a colony of bees in a box-hive the fall of 188S, and failing to secure any surplus in honey or swarms in 1889 and 1890, I decided to transfer this colony, win or lose. I read much on transferring, and sought to put into practice, at least.

About May 1 (apple blooming) I made preparations. A box eight inches deep and the same size as the bottom of the box-hive was made. An 8-frame dovetailed hive was gotten ready in this style: Four frames filled with comb were taken from four other hives (one from each hive), the outer frame being taken. No attention was given as to sections of frames. They contained in part some honey, empty cells, and perhaps eggs or cocoons.

BARNES' FOOT POWER MACHINERY

Read what J. L. Parent, of Charlotte, N. Y., says: "We cast the one of your Combined Machines, last winter, 50 satchel hives with 75,000 cap, 100 honey racks, 550 brood-frames, 2,000 honey boxes, and a great deal of other work. This winter we have doubled the amount of bees, etc., to make, and we expect to do it with this Saw. It will do all you say it will." Catalog and price-list free.

Catnip Seed Free!

We have a small quantity of Catnip Seed which we wish to offer our readers. Some consider Catnip one of the greatest of honey-yielders. We will mail to one of our regular subscribers one ounce of the seed for sending us one new subscriber to the American Bee Journal for a year with $1.00; or will mail to any one an ounce of the seed and the American Bee Journal one year—both for $1.30; or will mail an ounce of the seed alone for 35 cents. As catnip rock this seed is very small, better order soon.

GEORGE W. YORK & CO., 144 & 146 Erie St., CHICAGO, ILL.
brood. These four frames were placed in the center of the new hive, and two others with starters were placed on top of this brood-nest. With a blanket, smoker, cold chisel, and hatchet, we went to destroy and to build. The blanket was spread, and the old hive was placed on it, the new hive occupying about the same place as the old, while the old hive was placed about three feet and at right angles to the new hive. After smoke came the battle. I now turned the old hive bottom end up, and placed the box aforesaid on top, after removing the bottom-board. Then more smoke and hammering on the box to get the bees to move upward into it.

After ten minutes of such coaxing I lifted the box to see the catch. A surprise—about a good, big handful only. These were dumped out on a blanket in front of the new hive. Part started into the new hive while part went in the air. I sighed, and wondered how long it would take to get this colony moved into their new home-to-be at this rate.

I unred myself, as it were, and proceeded on my own "hook." The old hive was returned bottom side down, less the bottom-board, and cold chisel, hatchet, and man soon removed two sides and laid bare the comb and bees. I cut out those old combs, rusty and crusty. The combs, when out, one by one, were given a jar at the front of the new hive, and clinging bees were soon off. The third comb removed had the queen—she went in like a lady.

When all combs were removed I found I had a plenty—I think enough to fill 20 Hoff- man frames. It was old, perhaps containing comb that had been built 20 years, as the hive had been made of yellow poplar that now was so weather beaten and checked as to be thrown in the plow.

While queen and workers were surveying the new quarters, I arranged a supper with the fence separators, leaving out the sections. I now took up the comb pile and cut out all sealed worker-brood into strips of no particular length, but four inches wide, and put it in place of the sections. I put this in the brood-chamber, spread over the top a woolen blanket, put on the cover, and let them go at that. In a half hour from the time of beginning all was complete, and house-cleaning was in full progress.

The honey in the old comb was unfit for table use, so it was placed in three or four shallow pans about the yard, and the five combs that soon had the honey home. About two pounds of beeswax was rendered from all the combs after they were cleaned by the bees.

Twenty-one days later I examined the new home, and found most of the sealed brood hatched. I removed the old strips and put on a super filled with sections containing starters. There was no trouble, except that few on each of this colony 24 full sections of well-capped white honey, and gave another super. July 15 I took this super with the same results as before, making in all 45 pounds for this colony, besides a full house below, and lots of bees.

The rainy season closes about the middle of July. We have had the best honey-year since 1898—an abundance of white clover till the drouth began. Our prime swarm, cast June 3, has done as much as this transferred colony. I feel that I have been successful in this transfer, and would like to know if such a way would always be successful, say in a poor honey-year.

T. F. WEAV.
Fountain Co., Ind., Aug. 3.

A Pretty State of Things.
Mr. Editor will remember my new hive, that I was at so much pains to make. Twenty frames and painted a gentle clover green! Well, what do you think? About two weeks ago I gazed into its inwardsness and beheld what could be not less than 50 pounds of luscious honey in those combs.

One morning, this week, I noticed that quite a lot of bees seemed aimlessly flying before the entrance, neither bringing in stores nor flying to the fields for supplies. I thought appearances strange, and forthwith inspected that colony again. I raised some of the most attractive frames, and, lo! they were remarkably light, just heavy enough to account for the wax they contained. I tried another with the same results. Now, why is this thusly? In handling all the frames I found but few with a little brood, and not three pounds of honey to that colony. Ha! ha! I have the secret. Robbers! But how can that occur with a pretty strong colony and a small—three-inch—opening to guard !

But presently I saw the cause of the whole trouble. I thought I had made the hive-cover perfectly tight, but the thing had warped, and one corner failed to connect, leaving a space quite large enough to admit several bees at once, and then my conclusions were reversed and rapidly.

I transferred that colony into a 10-frame hive at once, before the little honey that was left could entirely disappear, closed up half the entrance, and saw to it that no more-

How to Get this Valuable Knife.—We send it postpaid for $2.50, or give it as a Premium to the one sending us 500 NEW Subscribers to the Bee Journal (with $2.50). We will club the Novelty Knife and the Bee Journal for one year, both for $2.50.

HONEY AN BEE-SWAX 
MARKET QUOTATIONS.

CHICAGO, Aug. 22.—White comb brings 15c per pound for the choice grades, with other prices at grade No. 1 selling at 14c, light amber and dark 10c, and dull 6c. East demand at 95c for white, and 85c for amber. Roots for yellow is 30c for choice yellow. R. A. BURNETT & Co.

CINCINNATI, Aug. 10.—The honey market is rather dull on account of the warm weather. Extracted sells out quite as rapidly as before, and prices are stiff. Better grades alfalfa water-white from 55c for 50 pounds. Fancy white clover honey sells from 15c. C. H. W. WEBER.

BOSTON, Aug. 19.—Our market to-day is about the same as yesterday. The demand for honey is still very weak, but prices hold firm. B. F. MOUNT & Co.

ALBANY, N. Y., Aug. 20.—We quote: Fancy white comb honey, 10c, 15c, 20c, 25c, 30c, 35c, 40c, 45c, 50c, 55c, 60c, 65c, 70c, 75c, 80c, 85c, 90c, 95c, 100c. R. E. SPENCER & Co.

OMAHA, Aug. 8.—New comb honey is arriving by express in small quantities from Iowa and Colorado, and selling at $3.50 per case in a retail trade. California, Colorado, and Utah have offered carlots at 45c/44c per pound, f.o.b. California shipping-points, but we have not heard of any sales having been made. The production of extracted honey seems to be quite large this year in Colorado, Utah, and California. PECKY BROS.

NEW YORK, Aug. 7.—There is some demand for new crop of comb honey and receipts are quite numerous for this time of the year. Prices have been principally from the South, but we have now beginning to receive shipments from New York State and near-by. We quote: Fancy white, 15c, No. 1 white, $1.00; No. 2 yellow, 45c. No new buckwheat is on the market as yet, and we do not expect any before next month. Extracted is decided to be good this year. Plenty of offerings, with only a limited demand, and quotations are rather nominal. We are receiving many lots of grade, according to quality, and Sothorn in barrels at 55c per gallon, 75c per gallon, dull and declining; for the present we quote 75c. 78c.

BILDRETH & SEEGREN.

DES MOINES, Aug. 7.—There is very little demand for any class of honey, although receipts of lots of near-by produced comb honey are on the market and selling in a retail way at $3.50 to $3.75 per case. We do not look for any large trade in this line before Sept. 1. Our market does not consume a great deal of the extracted honey. PECKY BROS. & CHANEY.

DETROIT, Aug. 12.—Fancy white comb honey, 14c/15c, No. 1, 13c/14c; no dark to quote. Extracted, white, 60c/65c. H. H. HUNT & Son. 79c.

BUFFALO, Aug. 10.—Quite a good demand for fancy honey, 16c/17c; No. 2, 15c/16c; No. 3, 14c/15c; old neglected. Advise moderate shipments only of new as yet. BATTERSON & Co.

SAN FRANCISCO, Aug. 14.—White comb, 11c, 12c, 15c; amber, 14c, 10c; 12c, 8c. Extracted, white, 55c—1 light amber, 4c/5c; and 6c/7c. BASKIN & CO.

Market continues quiet, with apiculturists, as a rule, unwilling to unload at prices generally named by wholesalers, except when the market is fairly represent as nearly as possible the values ruling at this date for several months. This market, being young, could not probably be effected at full figures, while, on the other hand, higher prices than quoted are being realized in the selling of some small orders.

KANSAS CITY, Aug. 6.—Some very fine Mis- souri honey is on the market, selling at 160c per pound for fancy white comb. Colo- rado and Utah white honey is dull and selling at 100c. Eastern states, both extracted and comb honey in cartons for first half of August, shipment at 8c per pound for No. 1, and 8c per pound for No. 2, f.o.b. shipping-point. The market for ex- tracted honey is as yet rather unsettled, asking prices ranging from 45c to 60c, and 75c for shipping-point. Buyers, however, seem to be in no hurry to make contracts. PECKY BROS.

THE
Bee-Keeper's Guide
Or, Manual of the Apiary,
BY PROF. A. J. COOK.
460 Pages—18th (1898) Edition—18th Thou-
sand—$1.25 postpaid.

A description of the book here is quite unne-
cessary—it is simply the most complete scientific
and practical bee-book published today. Fully
illustrated, and all written in the most fasci-
ating style. The author is also too well-known to
the whole bee-world to require any introduction.
No bee-keeper is fully equipped, or his library
complete, without THE BEE-KEEPER'S GUIDE.

This 18th and latest edition of Prof. Cook's
magnificent book of 460 pages, in neat and sub-
stantial cloth binding, we propose to GIVE
AWAY to our present subscribers, for the work of get-
ing NEW subscribers for the AMERICAN BEE
JOURNAL.

Given for TWO New Subscribers.

The following offer is made to PRESENT sub-
scribers only, and no premium is also given to
the two New subscribers—simply the BEE JOUR-
NAL for one year:

Send us TWO NEW SUBSCRIBERS to the BEE JOURNAL with $2.00, and we will mail you a copy
of Prof. Cook's book FREE as a premium, Prof. Cook's book alone sent for $1.25, or we club
it with the BEE JOURNAL for a year—both for only
$1.75. But surely anybody can get only TWO
NEW SUBSCRIBERS to the BEE JOURNAL for a year,
and thus get the book as a premium. Let every
body try for it. Will YOU have one?

ANOTHER
ENDORSEMENT
FOR
Root's Red Clover Queens

ALEXANDRIA, IND., Aug. 1, 1901.

THE A. I. ROOT CO., Medina, Ohio.

Dear Friends:—The tested clover queen came in good condition
and has filled seven frames with brood two weeks from the
day she arrived, which is better than the combined efforts of three
"yellow" queens purchased two years ago. I believe she is going
to be the counterpart of the queen purchased of you in 1896, in
which case money could not buy her.

Yours Fraternally, EVAN E. EDWARDS.

PRICES OF RED CLOVER QUEENS:

Gleanings in Bee-Culture one year and Untested Queen . . . . . . $2.00
" " " TESTED QUEEN . . . . . . 4.00
" " " SELECT TESTED QUEEN . 6.00.

If you want something you can not do better than to order one of these queens. All orders are filled promptly. No extra postage on these to foreign countries.

THE A. I. ROOT CO., Medina, Ohio.

APIARY OF GEO. A. ORMERT, OF DUBUQUE CO., IOWA.—(See page 580.)
The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

HOWARD M. MELBEE,
HONEYVILLE, O.

(THE CUT IS THE FULL SIZE OF THE KNIFE.)

Your Name on the Knife—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a lifetime, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise, to try to destroy the name and address, would destroy the knife. It is traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your Pocket-Knife will serve as an identifier; in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting momento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for $2.50, or give it as a Premium to the one sending us 25 New Subscribers to the Bee Journal (with $5.00). We club the Novelty Knife and the Bee Journal for one year, both for $5.00.

Free!
Glucose Not a Wholesome Sweet.—Dr. J. H. Kellogg, of the Good Health Publishing Company, and widely known as an authority on health foods, answers the question, "Is glucose a wholesome sweet?" in this way:

No. The glucose of commerce is manufactured by fermenting other starchy substances by boiling them with sulphuric acid. This form of sugar is quite unlike the sugar formed by the digestive processes. There is no doubt that the large use of glucose, or grape-sugar, in the form of candy, syrups, adulterated honey, and various other meretricious products which have been put upon the market, is responsible for a large number of cases of disease—a disease which is rapidly increasing.

We are often asked concerning the advisability of feeding glucose to bees for winter stores, or to keep them going during a drought. Our answer is, invariably, Don't. A certain bee-keeper who numbers his colonies by the hundreds, experimented in this matter last fall, by trying to feed something like a ton of glucose to his bees. He won't do so any more. We have been trying to get him to write out the results of the experiment for publication, but so far has failed to get him at it. We imagine that he is trying to forget his mistake as soon as possible.

In our opinion, bee-keepers can't get and stay away too far from the whole glucose business.

Big Money in Bees.—In the American Bee-Keeper, F. G. Herman does his full share toward inducing a venture into bee-keeping. He began with one colony and now has 60. He says:

It has been my experience and that of bee-keepers generally that there are fewer risks and larger profits in comparison to the amount of capital invested in bee-keeping than in any other business. Of course, emergencies do arise, but if they are met by ordinary foresight and common sense, they are not likely to result disastrously.

Now, that's encouraging. One prefers a safe business, even if the profits are less; and there are fewer risks in bee-keeping than in any other business. But it is cheering to know that in bee-keeping we are not confined to small profits, for there are larger profits upon the capital invested than in any other business.

If J. Pierpont Morgan had only had the foresight to invest his money in bees, he might to-day have been a rich man!

Without any desire whatever to harbor any doubts as to bee-keeping being the business of fewest risks and largest profits, one still has a secret longing for definite figures. There is comfort in looking them over and making estimates for the future. Fortunately Mr. Herman has given us just what we want. He says:

It is a conservative estimate of the bee-keepers generally, however, that each colony should bring in at least five dollars a year; and as each colony also throws off a swarm annually, it is easy to see how a little capital invested in bees will grow and multiply, besides yielding a very fair percent of profit.

Let us figure upon this basis, and see what Mr. Herman's income should be five years from now. As the number of colonies doubles each year, his present 60 colonies will in five years increase to 1,920, and as each of these "should bring in at least five dollars a year, his income will be $9,600, and in 10 years from now it will be $807,200. Note this that this is not the wild vision of a dreamer, but the estimate of bee-keepers generally. Note, too, that it is a conservative estimate. Each colony should bring at least five dollars. That's in the poorest years. There are good years when the income is ten, twenty, fifty times as much as in one of the poorest years. Let us continue to be conservative, and say the income will be only ten times as much. That will make the income in ten years from now a round three millions, with $72,000 left for loose change.

The only wonder is, that with all this there is such careful concealment of the names of all the millionaire bee-keepers.

Wild Statements About Bees are often made in the general press, and sometimes are copied unchallenged in bee-journals. The following paragraph occurs in the Pacific Bee Journal:

It is interesting to note in a northern California paper, in an article on fruit-growing, "having with a six-horse team a million or more bees "to fertilize them in his orchards to aid in fertilizing the fruit-bearing trees."

If each colony contains 50,000 bees, a billion of bees would make 20,000 colonies! Estimating the weight of each colony at 50 pounds, the whole weight would be 500 tons. Unless the six-horse team would make more than one trip a day, it would take the biggest part of the year to do the handling.

Extracting-supers.—"Loyaltoine," of whom the Australian Bee-Keepers' Review says he is a practical apiculturist, all of whose writings are well worth reading, differs in some of his views from many if not most of the bee-keepers on this side the globe. He advises a paint the use of shallow frames in extracting-supers, saying, "Full-depth frames pay best, as they hold more honey and require less handling." He also objects to barring the queen out of extracting-supers, because if the queen is allowed full range the bees will work better and not be so likely to swarm.

The editor of the same journal doubts very much that it requires less brains to work for extracted than for comb honey.

Hive-Covers.—A good cover is a very important part of a hive. At the present time the most popular cover is probably the plain board cover. Editor Hutchinson thinks there is nothing better for the North, and finds it hard to believe it is not the best anywhere. To this the editor of the Rocky Mountain Bee Journal replies:

Editor Hutchinson says in the July Review, that for hive-covers, "in the northern part of the United States, there is nothing better than a plain board of white pine, thoroughly cleated and painted; and it is hard to believe that this cover is not the best cover in any climate." That sort of a cover may be all right in the rain-belt, but if Mr. H. will come out here we will show him hundreds of such covers so full of checks that they afford little more protection than a sieve. We have experimented quite largely with covers for this climate, and have concluded that a plain, flat cover made of rough boards and covered with "Neopsonet Red Roofing," is about as good as can be devised. This fabric, when painted white, is a very poor conductor of heat; and if a new hive is started in spring, will remain water-proof indefinitely. Another merit it possesses is cheapness, costing only about 30 cents per 10-frame cover.

However well satisfied Editor Hutchinson may be with the plain board cover, it is not alone in the trying climate of Colorado that murmurs are beginning to arise against it. The plain board cover has its advantages. It is not expensive. No quilts or sheets are needed with it, and it is light to handle. When new, it makes a close fit, leaving nothing to be desired. But it will not always stay new. With time it will curl up at the edges, allowing cracks large enough for cold to enter, and sometimes large enough for robbers to get in. Still worse, it will twist so that it will not lie flat. Making the cover of several pieces (although it takes it out of the list of plain covers), and beveling the edges, will help against the warping that makes the edges curl up, but it will not prevent twisting. The bee-keeper who has thrown his bungling telescoping cover with its quilt is greatly pleased with the simpler plain cover, but he can not resist a yearning for the greater warmth of the discarded cover in cool weather, and when the sections melt down in his supers because the hot sun shines upon the plain board covers, he remembers that he
September 27, 1901.

never had any trouble of that kind in the olden time.

Some have expressed a desire for, or have already used, a cover approaching the plain house cover in lightness and convenience without its objections. It is a cover made of two surfaces with an all-space between. The upper surface is 3, inch stuff with the grain running lengthwise, and a lower surface of the same stuff with the grain running crosswise, have between them an air-space made by strips of 3, inch stuff between the margins. In other words, a shallow box closed top and bottom with an all-space between the box being 's, inch stuff. Of course it must be covered by tin or some cheaper material. The grain of the two surfaces running in opposite directions makes all warping and twisting impossible. The dead-air space is a good non-conductor, making the cover warm in cold weather, and cool in hot weather. Each cover may possibly be the coming cover to be what Editor Hutchinson believes the plain cover already is, "the best cover in any climate."

Deep-Tubed Honey Plants.—Until lately it is probable that most bee-keepers have thought of the red clover as the only honey-plant with tubes too deep for the reach of ordinary bee-tongues. Red clover is far from being the only one. Editor Root says this in Gleanings in Bee-Culture:

In addition to the great honey-plants, red clover, buffalo clover, and sorrel, in Texas, that have long corolla-tubes, I can now add to the list the mountain sages of California, especially the white sage. This last has quite deep corolla-tubes; and I was told, while on the coast, that unless these corolla-tubes are very full the bees do not get Much honey from this source. This is exactly the case with red clover. So it appears that long-tongued bees, if good in the North, will be in Texas that have these sages throughout Central and Southern California, as well as throughout all those states that grow red clover; and I have been surprised to find so much of it in the West. It appears, then, that if long-tongued bees are an advantage on red clover, it will be equal advantage in the case of all the other honey-plants I have named.

Everything was in as neat condition as possible. The apiary is at the rear of the dwelling house, in a beautiful flower-garden, except that around the hives there was not a flower, weed, or blade of grass. All was clear, and each hive easy of access.

Mrs. York accompanied us on this little trip. We spent a lot of time with Mr. Clarke and his parents, with whom he lives. They are about 70 years of age. Mr. Chas. Clarke is the only "child" at home. Of course he is quite an old "child" himself. He has never taken unto himself that which would make him to be the "besser half." We suppose his good mother could hardly spare him, as he is as handy about the house as most daughters would be.

Mr. John W. Clarke, his father, has a justice court in that part of the city where he lives. He has been "handing out" justice for nearly 30 years, and, we believe, has never had one of his decisions reversed. When he "decided" that "Mr. Clarke" was not in the bee-business, it was a wise piece of "justice," as he has been clearly proven by the good crops of honey the bees have gathered for him.

More on the First 1000.—Still they come. We mean members of the National Bee-Keeper's Association. During the past week we have received the following names with $1.00 each:

B. H. Beecham, A. L. Jenks,
Richard Chinn, W. A. Frank,
W. M. A. Taylor, O. P. Hendrix,
F. Z. Drexler.

DR. C. C. Miller, of McHenry Co., Ill., wrote us Aug. 27, as follows:

"After the terrible drought which nearly or quite stopped the rearing of brood in July, it seems a great blessing to have a steady and fairly good fall flow which will leave the colonies with plenty of young bees for winter. I have also taken advantage of it to make some new colonies."

Mr. C. H. Lake, residing near Baltimore, Md., wrote us Aug. 27:

"Bees did poorly here this season, except in one pasture where I had raised my crop of honey for three seasons past."

Mr. Geo. A. Ohmert and Flaley, of Dubuque Co., Iowa, are shown in our front-page illustration this week. When sending the photograph, Mr. Ohmert enclosed the following:

Friend York:—I started in the spring of 1901 with 18 fairly strong colonies, and 10 very weak ones. They built up through April and May, but for the rest of the month I lost white clover cause, which was very abundant, and the bees began to swar. There would be from three to five swarms of the same time, all mixed together. We would have a great time dividing them, but we finally got them settled down.

We harvested about 900 pounds of white clover honey. The basswood flow lasted only about four days, and then our great drouth was on, and the honey-flow stopped.

We had 400 well-filled sections, leaving all the partly filled ones on, and the most of it was carried down during the drouth.

We have had three colonies, with plenty of honey, providing we get any kind of a fall flow, which I think we will, as the drouth was broken to-day (July 28) with a very heavy rain.

I was expecting to go to Buffalo this fall at the bees' expense, but we lost our raspberries and blackberries, so the bee-money must have to go to making up that loss. We have a picture of a part of our apiary. We could not get it all in. The little boy up towards the house is my main assistant. Mrs. Wimert is sitting on a chair under a tree. Our youngest is standing by me. We have one more little girl in the picture, and the rest are neighbors' children.

In front you will see my home-made extractor. It works all right, and is away better than the small extractors I own. The cost, outside of the work, was $8.25. I can extract partly filled sections very rapidly.

Geo. A. Ohmert.

Mr. F. Danzenbaker wrote us Aug. 29, that the severe illness of his wife makes it impossible for him to attend the Buffalo convention. We trust she may soon recover. It will doubtless be quite a trial to Mr. D. to be deprived of being at the convention, for he enjoys such gatherings.

Mr. Tros. Dougery, of Bureau Co., Ill., called at our office last week. He has been keeping bees, off and on, for 40 years. He now has 25 colonies, and reports a good season. Mr. D. says he can get one or two cents per pound more for honey in the tall 4x3 sections than for honey in the square sections, in his local market.

Hon. Eugene Secor is on the program of the 21st annual session of the Farmers' National Congress, to be held at Sioux Falls, S. Dak., Oct. 1 to 10, 1901. His subject is: "Some Problems Confronting the American Farmer." Surely, he has an extensive text, and one that permits of considerable latitude in its discussion.

The Apiary of Louis C. Koehler (see page 555) is situated in Manitowoc Co., Wis., and contains 185 colonies of bees, all in 10-frame Langstroth hives, except a few which have been for experimental purposes. This apiary was started 20 years ago with five colonies of bees, and it has proved to be a success, although there have been set-backs and poor seasons. His father calls it the "big circus," and their farm he calls the "side-show."

The apiary is run entirely for extracted honey, which is all disposed of in the home market, being sold at cost to the consumer. The white clover and the basswood honey are sold at 10 cents per pound, and the goldenrod at 9 cents. In the neighboring cities he has disposed of about three-fourths of a pound per capita on an average; he thinks this a pretty high average, and would like to hear of anyone who has done better. Mr. Koehler has a honey-house 10x28 feet floor-space, and 12 feet high. The lower floor is divided into two rooms; one is the extracting-room, 10x16 feet, and the other is the honey-storage-room, 12x16 feet. The second floor is used as a store-room for empty boxes, frames, etc., and as a paint-shop. He uses extractors on his father's own invention.

Mr. F. Wilcox, of Juneau Co., Wis., dropped in to see us Sept. 2, when on his way East to attend the Buffalo convention, and visit that part of the country. He reports the fall honey crop a failure in his region, but the yield from clover was good, especially aliske clover. There being several days of cool weather just at basswood bloom, the yield from that source was not very good.

Weekly Budget.

Mr. Charles Clarke is a bee-keeper. He is a bee-keeper of not many years' experience, but he is good bee-keeper. He knows how to produce honey. He knows how to handle brood, too.

We made our second visit to Mr. Clarke's apiary Thursday afternoon, Aug. 22. He lives about 12 miles south of Chicago, in a splendid sweet clover district. He began last spring with about 30 colonies, has increased to nearly 60 colonies, besides taking off, something like 4000 pounds of as fine comb honey as we ever saw, and will likely have 10000 more pounds.

Mr. Clarke has just completed a new honey-house, in which he had the honey all tiered up on shelves made of planks on edge and 2x2 inch stuff on top of them. It was a splendid arrangement for the very best curing possible before being put into cases for market.
Contributed Articles.

Transferring Worker-Comb for Drone-Comb.

BY C. P. DADANT.

In reply to a question on this subject, I would say that it is indispensable for the novice to learn how to transfer combs properly, for many reasons. First, he may have bees in old boxes, swarms hived in haste, in any kind of a receptacle—a dry goods box, a cracker box, a keg, or perhaps even a hollow tree, though the latter are getting scarce when compared to 35 years ago.

Then, there is the exchanging of drone-comb for worker-comb, as mentioned in the query. It is also sometimes necessary to straighten combs, or even to take them out entirely, if not built true in the center of the frames; for a movable-frame hive deserves its name only when each comb hangs true on a separate frame. Before the invention of comb foundation, it was much more difficult to secure straight combs, and apiarists had recourse to all sorts of devices to compel the bees to follow the straight line. These devices were more or less successful, and for that reason the handling of the frames in the management of the apiary was more difficult than today.

It must be borne in mind that drone-comb may be removed with the best results when the combs are dry, and so the time for this work is early in the spring or during a dearth of honey.

When examining the frames, set aside all that have more drone-comb than worker-comb, and cut out every-other thing. This will give you a number of pieces of good worker-comb to use. The frames that have been thus emptied can be supplied with either a strip or a full sheet of foundation, and placed in a hive in which a swarm is to be hived.

It does not matter how small a piece of worker-comb you may have, do not destroy it, unless it is absolutely too old and dirty or crooked. Small pieces may be used as well as large ones. I remember that my father, when I was yet a boy, used to transfer into our hives the combs of small boxes in which we had received imported queens from Italy. At that time the exporters put up the queens for shipment in small boxes with two frames of comb, each about 3 x 4 1/2 inches. My father would make a very decent frame of comb with some 16 of those pieces arranged symmetrically in the frame, four in the length and four in the height of the frame. With a little labor from the bees, we had a very good comb with no drone-cells, except an occasional one at the seams, and it is certain that those combs could still be found in our hives, showing plainly the suture or seam made by the bees. I may say that at one time we imported as many as 300 queens annually from Italy.

To hold the combs in place, we use a light wire, say No. 16, of about the height of the frame, and with both ends bent at right angles, so the wire may be driven into the wood at the top and bottom. It is well to punch a small hole previously, with an awl, for it helps in driving the wire into the wood. A number of these are put on one side of the frame, and the frame is laid on the table with the wires on the underside, then the piece of comb is fitted, and more wires nailed on top of it.

To fit a piece of worker-comb into a gap from which a drone-comb had been removed, lay your spare piece of worker-comb on the table, then put the frame down upon it with the empty space of the comb, you can thus mark the exact size and shape of the piece to be cut. This is marked with a sharp knife. If the cut is made exact and the combs are rather old, the fit will be so good that no support will be needed, and the bees will have them fastened together before there is any danger of the patch coming to pieces.

In putting in small pieces shorter wires may be used. (See engraving.)

There is no need of leaving the wires on after the combs have been repaired by the bees. If you leave them, it will spoil a row of cells all the way up and down along each wire. Usually a week is amply sufficient to have the combs patched and in good order, unless the colony is weak and the weather is not favorable.

If transferring is to be tried during a honey-flow, it is necessary to extract the honey out of the combs first. Under no circumstances would a good apiarist transfer combs during a hot spell of weather, especially if there is a good honey, unless the combs to be handled were old and tough.

Never destroy good worker-combs, unless they are so exceedingly dirty that it is evident that the queen would not, or could not, lay eggs in them. That is usually the case with the lower edge of the combs of a very old hive. But if the combs are clean, age makes no difference; we have combs over 40 years old that I would not exchange for the same area of foundation.

Some writers will tell you that bees can build combs so fast, and so cheaply, that a swarm hived on empty frames will succeed as well as one hived on combs already built; but you must class them with the farmers who tell you that land without manure can be kept as productive as land that is well manured. Such talk makes a diversion, it causes discussions, and breaks the monotony by causing the heads to warm up; but in the long run, all the fine-spin theories give way to plain facts. Hancock Co., Ill.

Hiving Two Swarms in One Hive.

BY C. DAVENPORT.

LAST year I wrote an article for the American Bee Journal, in which I stated the fact, and endeavored to explain why a good deal more surplus when two swarms could be obtained here if two swarms were hived together in one hive than could be if each were given a separate hive. In commenting on this in his inimitable way, Mr. Hasty compared it to Hamlet with Hamlet left out, and from what he further said I infer that he has had, or thinks there would be, trouble on account of the queens being balled.

But in the hundreds of natural swarms I have hived in this way I do not remember a single instance when any trouble on account of one or the other was ever taken to prevent it; that is, when both swarms issued at or about the same time. It would be of interest to me, if Mr. Hasty would say whether he ever had any trouble of this kind, or only thought there might be.

Of course, with artificial swarms, or when two natural swarms that issue on different days are hived in one hive, precautions have to be taken to prevent the bees from fighting, but this is not done with any special regard to prevent the queens being balled.

What leads me to say more on this subject is that soon after what I wrote last year was published, a friend of mine, who keeps bees in a small way, came to my place and wanted to know much more in regard to the matter that I had explained, and was much pleased to find out that natural swarms that issued a few days apart could be put together so they would work as well as they would when they both swarmed the same day; when this occurred he had trouble in getting both swarms to work properly together in one hive, in which case he knew from his own
experience that nearly as much again white honey could be secured. The swarms are our friends.

It is a simple and easy matter to unite successfully swarms that come out within three or four days of each other. All that is necessary is to have the swarm that issues last in a separate hive, and leave it in this till evening. Then, if there is any honey in it, or the bee-keepers are soldiers, there is a chance that it is desired to unite it with the bees of this swarm, that issued first. Now, smoked enough so they will thorougly fill themselves with honey; or the plan will work if there is no honey in the hive for them to fill up on. If they are smoked again, some of the soldiers are induced to go with them.

The swarms are now all shaken, in any way most handy, down on the ground in front of their hive. Then the bees of the last swarm are dumped on top of them and all allowed to crawl into the hive together. The whole operation need not take more than a half hour, and the bees are then left to work for themselves. The bees of the last swarm need no smoke if they are united the same day they swarm, but the plan will also work just as well as if the second swarm is left until the swarm comes in which they would need to be well smoked, and, of course, the hive that contained one swarm would, the first day, have to be set close beside the other, or the bees from the swarm moved would return to the location and place where their hive was first set. If there is a laying queen with each swarm, and no hive have I no particular preference as to which survives, no attention is paid to them. Of course, one is always killed, and this is probably inevitable done the first morning. When a queen is separated by other means, settled by royalty itself, I am not able to say, but my opinion is that the bees are not guilty, for I have often noticed these queen that would have found dead in front of the hive this month. There are not many in this way, but quite a few, and the queen's bodies was not gnawed or marred up, which, so far as I have observed, is usually the case when a queen is balled and worried to death by the bees. However this may be, I never knew one queen to fall to survive, though when one queen was larger than the others, and the young hives were the virgin queen in the last of the virgin queen is the swarms. The importance, in my opinion, is that there were nearly three full swarms in it. Of course it was carelessness, and might have been prevented.

The hiving of two swarms together is very profitable with ordinary bee-keepers. Others do not meet with the same success; we can not obtain the same results with the same plan. For instance, in the American Bee Journal for May 24, 1900, is an extract from the Canadian Bee Journal in which Mr. L. M. is quoted as saying that the largest and most successful bee-keepers—so quotes are:

"We hived every swarm on half comb and half foundation, full sheets of foundation (four sheets to the pound), placing the old colonies alongside the new swarm; six or seven days after we shook the old comb, and regathered them in front of the new comb, making it very strong, and took the brood away and hived a swarm on it. There were no eggs and little or no nectar long. Every swarm of bees that started for Comb, except a few that were started for itself, went to work; we carried that out throughout the season. We started with 290 colonies of bees and we finished with 212, and we took 25,000 pound honey.

Previous to what I have quoted he said that this was comb honey. I was much impressed with this plan, and the results obtained from it, and last season I tried it in quite a large way, but the whole thing was practically a failure. The honey was too soft, and the combs were not readily worked, in other ways, and it would not seem to be to much interest of many if others who tried the plan last season would report results. I do not mean that the plan may not be all right—

I only wish to insinuate in a mild way that an expert did not enough to make the method a success. I have, with me, swarms would in some cases refuse to stay on those combs containing, as they did, and must when this plan is practiced; a great deal should be done. I would often, instead of a guard or clipped queen, they did not work with anything like the vim and energy that a swarm hived on starters would, and the results in section work with swarms, either natural or artificial ones, if, as is the case with me, sections filled with white honey is the object sought, regardless of increase or store in the brood-chamber, is to have a large force, in one hive with small starters in the brood-chamber, and use full sheets in the second section. If, with a good one, it will occupy most of the comb below as fast as it is built, so the honey must be in store in the sections; and, what is of more importance, the bees under this system work with great energy from the start to the end of the fall.

There are some disadvantages about this plan, such as pollin in sections some seasons, and all seasons a good deal of drone-comb below. Southern Minnesota.

Bee-Keeping on the Island of Sicily.

BY F. GREINER.

The peasants of Sicily, in particular those living along the Southern coast of the island, have followed bee-keeping as a business for a great many years. The movable comb and the divisable brood-chamber have been in use among them for centuries. Indeed, it would be difficult to frame any description of the countries' origin, or originators of their hives and methods were.

The bee-knowledge these people possess has been transmitted to them by the Greeks and Romans, and, according to some recent ideas on this subject, from a single, ancient honey tree. The idea is that the bees, with the help of the natural climate, can make sufficient pollen in Sicily, and that in the island grows a tree, the resin and gums of which are used by the bees for a part of their materials. In this tree, the long idea hive has its origin.

The peculiarity of the hive is, that the frames form the hive. Nothing more simple could be thought of in the shape of a frame hive. Of course the frames must all be of exact size; they are fastened one to the other by small wooden pins. As many as 42 such frames are thus united, and all the interstices and joints are filled and covered with a mixture of clay and fresh droppings in order to exclude water. Only two small entrances at one end are provided for this 5-foot tunnel.

The method of managing these hives is as unique as are the hives themselves. It is a well known fact that the brood-nest in a hive is generally located near its entrance, there being no building done far from it. If honey is wanted, a part of the frames at the front of the entrance are separated, and empty ones are substituted; if increase of bees is desired, a part of the frames at the front are separated, and thus the division is made.

The dead-air spaces in the frame material, as well as the covering above mentioned, seem to be sufficient protection to prevent bees eating down as fast as in hot a climate as Sicily.

By O. C. N. Y.

P. S.—The above information was gained from an article written by V. Rauschenfels, in Imkerzeitschriften, by F. G.

Rearing Queens—Help for Those Who Fail.

BY G. M. DOITLEET.

A CORRESPONDENT writes as follows: "I have attempted, the past summer, to rear queens as given in your book, but the bees lowest your directions. Where does the fault lie, me or the bees?"

It seems a little strange that about one in 100 who try the plan of rearing queens as given in my book make a partial or entire failure of it. Of the other 99 who try, ninety report a perfect success, while the other nine are puzzled and perplexed over not being able to do better than to secure from three to five perfect queens out of every lot.
good queens at any time of the year these conditions should be brought about as nearly as possible.

Of late years in the trial of comb and fall rearing, I slip a sheet of perforated zinc down into the hive so as to confine the queen to one side of the same, when queens are reared in the other side, or the side not having the queen, the same as in upper stories. This can be done when there are not enough bees to fill properly two stories so as to rear queens to the best advantage.

Onondaga Co., N. Y.

Questions and Answers.

[CONDUCTED BY]

DR. C. C. MILLER, Marengo, III.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail—E. R. R.)

Transferring Bees from Box-Hives.

1. I have several colonies of bees in box-hives that I wish to transfer to movable-frame hives. They have each considerable honey in the brood-chamber, and I suppose brood also. Would it be as well, or better, to do it now (Aug. 3) or wait till September? If it is done September it is to be done in the same way as doing successes do: if not another make the same success in Ohio, providing he did exactly the same thing.

As 60 out of 100 make a success with the plan, it would look as if those who make a partial or entire failure in the matter, failed, in some respect, to work in all the ministrations of the matter, in the same way the successful ones do.

As I mistrust that more fail in the matter of transferring the larva than anywhere else, I am constrained to give the fullest possible directions in this matter.

To those who have not succeeded as they desire, I would say, make a colony queenless and then wait three days till queen-cells are formed having plenty of royal jelly in them, and, after having removed the larvae occupying these cells from the royal jelly, transfer larvae from your select breeding queen to the royal jelly, left just as you removed the original larva from it, making the cells worked upon by some other worker. You will find about half all the trip above every cell thus gathered, when you will return the combs to the bees. If this is a success you may know that there is no trouble on your part in the transferring process; but if it fails you may make up your mind that you killed the larvae in some way in manipulating them, for with me every one is accepted under such circumstances.

If you succeed here, try the same way again, only set the frame having larvae transferred to the cell built by the bees, in the upper story of a tiered-up colony; and, if I am not greatly mistaken, you will succeed here also, unless your trial is made in early spring or late in the fall. If you succeed in this trial, and artifices upon the successful ones do, when you may know that there is some mistake in your manipulation of the royal jelly, or else the wax used in forming the cell-forming is offensive to the bees, or not fashionable. Should you find one of these reasons, or any from these is the cause of failure, instead of using royal jelly, transfer the larvae to the cell-forming by the Willey Atchley plan of removing cocoons—larae and all to the cell-cups. If you now succeed you may know that the trouble was in manipulating the jelly. If you do not, then the cups are at fault.

If you have made no success with any of your trials till you transferred the larvae by means of the cocoons, then you probably have failed at the artifices upon the successful ones do, in such a way that you killed the same, and here is where you are to look for the trouble. If you know that you failed in handling the larvae, allow a few suggestions:

Make the point of the quill used in transferring very thin and three-thirty-second broad, rounding the extreme point. Have this done, give the jelly is coming in from soaking it in water for some time and then pressing it, while soft, on the thumb-nail till it will fit the bottom of worker-cells nicely, when it should be laid away for 24 hours.

Now, before trying to transfer the first larva, dip the point in royal jelly till it is thoroughly moistened with the same, when you will note that, as you pass it under the larva, said larva is floated up on this royal jelly adhering to point, and then you will not have quill sticking to the quill at all, so can not be injured if you use any care in setting it down in the royal jelly in the cell-cups. If you are bothered about seeing, shave the piece of comb containing the larvae, or throw the larva or nest, or base of the cells, when no one should have any difficulty in seeing perfectly who can read the print of these pages.

But perhaps you tried the plan of queen-rearing too early in the spring, or during cool weather in September or October. Or perhaps you did not feed the colony when house fields, or did not, have unseamed brood in the upper story; any or all of which would tend toward a failure.

If the weather is cool and no honey coming in from the fields, the bees should be fed till they are all alive and active, the same as they are when honey is coming in from the fields and at swarming-time; for, if we would rear...
enough of the upper part to make a sung fit in the frame. If, however, there is drone-comb at the lower part and none above, of course you will discard the lower part.

3. There is as much danger of robbing at three rods apart as three feet.

5. You will need great care, especially if done late in the season. If the hives stand close together the danger will be less.

6. Your idea is all right, only moving at night will not be any different from moving in daytime. You can’t fool the bees by that trick. But you may shut up at night the hive to be moved, keeping it shut up for 24 hours (look out you don’t mistreat them). Then open it the next day about once at once, or any time within the 24 hours, and pound on the hive so as to stir them up thoroughly before opening.

7. It is never too late to build comb if it is needed, and the reason your bees build none is without doubt because they need none. Even if you take a comb right out of the middle of the brood-nest, the capacity will be allowed to remain if they have so much room elsewhere that they are not desirous of more.

8. No, in rare cases where there is special reason for it, they may build comb in winter.

9. Almost any time at your own convenience. If you use wire, it will move them themselves, although it will be a help to them if you find it convenient to remove it. If you use fine wire, it will do no harm if you leave it for weeks, so you can remove it any time you happen to have an opportunity. Either wire or string may be removed just as soon as the bees have fastened the combs in the frames just a little. In the working season, this will be in a day or two. It is a good plan to look at the work in a day or two for sometimes the combs will not be located centrally in the frame and you can easily crowd it into place before they are too firmly fastened in.

10. Yes, and no. The part of the comb that is used for brood-rearing will be about the same when turned upside down, but the deep cells in the upper part of the frame that are used for storing honey will be found to be slanted so much that the downward slant will be objectionable when reversed. It will also give the bees some trouble to cut down these deep cells to the proper depth for brood-rearing, and if it will well to try to make the combs right side up, but if it makes such inconvenience to do so as put them in any way that comes handy.

11. As already mentioned, if you shut up the bees for 24 hours it will greatly help to make them stay in the new place. If you wish to make them quiet a day or two before moving, they will stay better in the new place. When the change is made, make the old spot look as unlike home as possible by taking away the stand, and perhaps making other changes. One way may be nearly the reverse of this. Leave on the old stand a hive with a frame of comb for any returning bees to cluster on, and in the evening return them to the new place. You will not need to repeat this many evenings.

"The Hum of the Bees" in the Apple-Tree Bloom is the name of the finest bee-keeper’s song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "Hummer," furnishing a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at $1.00.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions. From which ways we offer valuable premiums in sending every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last.

THE AFTERTHUGHT

The "Old Reliable" seen through New and Unreliable Glasses.

By E. E. HASTY, Sta. B Rural, Toledo, O.

TRYING TO CORRECT POPULAR TERMINOLOGY.

No, Prof. Cook, it’s entirely a waste of energy to try to make the general public quit saying "worms" and "bugs" for larvae and beetles. To give up the effort is the only sensible thing that can be done—excepting of course in distinctly scientific papers. The people have worn in many such cases with special interest, being on the side 100 to 1. The people love short, smoothly-sounding words and "larva" is "out of court" to begin with, by its un-English look and sound. Worse than all, many folks take a revengeful delight in using words that they know scientists "frath the month" about, to pay them up for the jaw-crackers they have made us, and which we all have to mouth because there is no alternative word. Deep and penalent reform will have to begin with the Solons themselves before the people will seriously think of reforming. Page 470.

MOVING BEES TO BUCKWHEAT FIELDS.

F. Greiner has a decided "method" in getting bees to the buckwheat fields. Or, rather, I should say he is trying to think it. It would run off the track at the same point, and be less satisfactory than the old "just move 'em" method; but his assurance that he finds it an improvement, and can recommend it to others, should make a good word. He encloses cans of empty comb, reuniting later or not reuniting later (according to circumstances, and according to one’s desires in regard to increase.) Page 484.

HIGH VALUE OF QUEENS DEPENDS ON THE OWNER.

As to the $200 queen racket, I guess I won’t say much—just stand by and laugh. O yes, there’s one thing I will say. The real cash value of an extra queen depends most of all on who has her. Page 484.

THE BLACK BEE AND CAREFUL BREEDING.

Black bee never coddled, and fused with, and "bred" as the Italian bee has been. You’re right about that, Mr. Thaddeus Smith. If somebody would breed out their miserável habit of running down and dropping in little bunches from the comb, the black bee would be an admirable and desirable variety. Spect the real gains of bee-breeding are mostly in the future (if it’s to be), and may be the black bee will get an even chance yet. Page 486.

BEES TOO LONG QUEENLESS.

So the circumstances may be such that bees left too long queenless before giving a cell got so excited and lunatic on the subject that they will all take their young queens and go when said queens do emerge. We will do well to make a note of it. I doubt somewhat whether they waited for wedding-night, as Dr. Miller suggests, as they may be quite wrong; and anyway that is not important. Page 488.

MULBERRY HONEY.

Fruit honey has a dreadful reputation for killing bees in winter; nevertheless a fruit 87 percent sugars, and affecting the human palate as a pure sweet, may deserve further trial. Would have to go it pretty strong in raising mulberries else the birds would eat them. Further, I tell them by try them in Southern California, where there is no wintering problem except to ward off starvation. Destroy the brush surrounding the bee-ranch and cover the hillside with mulberry bushes. Then when a famine year comes tell the bees to go harvest for themselves. Page 493.

SOME "HOT" POETRY REVIEWED.

If it were a youth publishing a poem for the first time I’d have mercy, but (having a little of the David and Goliath spirit) I’m going to go for Eugene Secor as he stands on page 514.

"And flowers to yield the dainty drop
When heat and drought have caused to dry up."

That is not doggerel; it’s prose. The writer should have taken timely warning from the fate of Stenog, whose sin was smaller than this one. Usually false rhyme and lame metre and reckless changes of form go in company with emptiness
of thought and substance; but it is not so in this case. The thoughts are not all above criticism, but there is a good supply of them, some of them gather up poetry. The trouble seems to be that he was too mortally lazy (probably on account of some hot July days) to correct the metre of a few lines.

"Is praying in animal language for rain?"
is a nice amphibrachic line—but, as there isn't another one in the poem, it rather jars us when as rocking back and forth in iambics we unexpectedly come upon it. The time has entirely gone by when one could afford to be "slightly" in the techy of his published poetry.—We thought one else would "straighten out" this matter, so we let the "poem" appear just as it was written. Hot weather is often responsible for over-heated brains—and some other things. —Boston).  

COLONY AND PRIME SWARM "REPEATERS."

On page 493, C. H. Harlan contributes an extreme case of the repeating of both prime swarm and old colony. One year in the long ago (not very far from 35 years) we had the same sort of swarming here. It was a warm and showery summer; and the crop that year was not very large. I have no records going back so far as that, and so can not tell whether his bees made better time than ours or not.

* * *  

The Home Circle.  

Conducted by Prof. A. J. Cook, Claremont, Calif.

THE BIBLE.

To our friends—all the American Bee Journal home circles I count as my friends—we enjoy to talk of those we love, of what we love. A man of old who had visions of truth said, "Out of the abundance of the heart the mouth speaketh." What more fills our hearts than our real, true friends. We must talk of them. What will make the genuine American patriot light up with gladness and enthusiasm? The mere mention of such names as Washington and Lincoln. They were—ever will be—glorious friends of us all. How our eyes brighten, and how our faces kindle at thought or mention of them. How our tongues are loosened as we speak of the nobility and grandeur of their lives. They were friends whose blessings acts touch each and every one of us with blessings that ever grow with the ages. We ought, we must, we will, always sound forth their praises with most hearty accents and with fullest accord. It is good for us and the world that we are all ever ready to voice their incomparable virtues.

And so our friends in all the walks and relations of life must be in our words, as they are in our hearts. We must voice the praises of our country, our State, our neighborhood, the dear ones of the home circle. Why will the coming reunion of bee-keepers at Buffalo be such a glad occasion? Why will all be so enlivened, and why will all who that stay at home lose so much? Only because we love our work, and we love to talk of its needs, its successes, its projects. To talk of these to those who are so fondly enlisted as we are, gives new impetus to our life and work.

I love my new home in Southern California. If we may judge from its rich gifts, it loves me. Ought I then to tire in singing its well-merited praises?—my visit to the home circles last week. I referred to a friend who, like its Author, is "too wise to err; too good to be unkind." Who next to its Author is our very best friend. Who with its Author is ever coveting for us the best gifts, and ever urging us to such life and action as will as surely bring such gifts, as will the breathing of pure air bring life and vigor to our bodies? I hardly need say that I refer to "The book of books"—the blessed Bible—for there is no other such friend.

Few of the blessings of my childhood and early youth rank at all in my esteem with the fact that daily I heard my dear old father read from God's Word. To-day the very accents and the oft-repeated comments on various passages are among my most treasured memories. Had my very busy father neglected this opportunity, how much of richest value and blessing would have been omitted from my life. Thus early I learned to love the grand old volume. In all my college life it was my daily companion, and ever urged me to my best work. Later, as I came to California, it came with me as my dearest friend; and as I went to teach, away up in the mountains, in a rude mining town, where there was no church and no profession of Christianity, its aid stayed by me.

As I started a Sunday-school, and gathered the dear, eager children together, it was from choice my first and best, and most excellent, assistant. There were great temptations in these days. But there were two precious friends ever close, to sound in my ear the ringing word, "Don't!" Need I say that these were the mother-love and the blessed Word? I am glad that later my own home repeated the good habit of my father's home; that my children, like his, daily heard the blessed word of truth. I rejoice that my own children, who now have their own homes, and their own special temptations, continue the habit. This, of course, takes them to the Sunday-school, and makes them its earnest supporter.

Oh, it is a good and a blessed thing for all our children to receive into their hearts and lives the blessed truths of this most blessed of books. I wish I might be so happy as to say the magic word that would open its pages, and speak its saving messages in every home circle of our land! What a power this would become, to check untruth, to stay dishonesty, to snatch away the victims of idleness and the horrid saloons; to weed out the foulest blot of all on our history's pages—the sin of impurity and the blasting social evil.

How certain is it that the authors of this grand book spoke as they were moved by the Spirit of God, else we would not have had the oft-repeated invitations to what all experience proves to be the highest virtues—would not have seen urged over and over, to a life that all experience shows will bring happiness; would not have been warned, almost on every page, against those evils and sins which surely imperil the soul. How black is untruth and dishonesty; how thick the Bible warnings to thrust them wholly from our lives and thoughts. How blasting and full of menace is intemperance and lust, and how over and over the dear old Book points the warning finger, and says, Touch not.

Oh! I would not only read it, but with the children I would learn so we could often repeat the Ten Commandments, the many grand passages from Isaiah, such Psalms as the 1st, 5th, 19th, 23rd, 24th, 121st, etc. Such portions of the New Testament as the Beatitudes, yea, most of the Sermon on the Mount, the 12th Chapter of Romans, and 13th of 1st Corinthians. "For if these be in us and abound, they would make us that we could not be barren or unfruitful."

That grand chapter from Paul's great heart—the 13th of 1st Corinthians—is almost enough in itself to guide us in all life's perplexities. Learned aright, and we can not go astray. I like to repeat it often together about the morning table. It is easy, by use of such transcendent passages as these, to show our dear children the glories of this the very Word of God, that they will hunger to know more of its divine truth, which, if well and rightly learned, will make us all "wise unto salvation."
Bees that Have a Record

(See page 459 American Bee Journal.)

Have longest tongues, handsome, gentle, great haters for honey, all tested queens, and sold at rate of $8 per dozen. By return mail.

HENRY ALLEY, Wenham, Mass.

Please mention Bee Journal when writing.

Queens! Queens!

From honey-gathering stock. Tested, $1.00 untested, 75 cents. "Shady Knoll Apiary." JAMES W. B. SHERMAN, 25 A.M.

SAC BARBOSO, New York.

Bee Wax

We will pay 25c. cash, per lb. for pure, bright yellow beeswax, and 25c. cash, per lb. for pure, dark beeswax delivered here.

CHAMBERLAIN MEDICINE CO., Des Moines, Iowa.

Please mention the Bee Journal.

Bee’s Did Better This Year.

Our bees have done better this year than for two or three years past, after all the dry, hot weather. We commenced the spring with 11 colonies, and increased to 17. We have taken off over 500 pounds of comb honey, and have about 150 pounds on the hives yet to be taken, which is pretty good for our locality. We can sell our honey at a pretty good price—comb honey at 30 cents per pound, and extra at 25 cents; and custumers furnish their pails.

RICHARD CHINN.

DIXON CO., NEBR., AUG. 26.

Working on Buckwheat.

Bees are working on buckwheat and queen-of-the-meadow present. I have taken off nearly 40 pounds of honey per colony, so far. C. F. CARR, M. D. AND H. HOUSE.

Omeida Co., N. Y., Aug. 21.

Horsemint.

I send a flower that grows here on the sand hills. The bushes are just covered with bees from morning till night. It gives considerable honey, although a light amber.

HENRY ROGERS.

Coke Co., Ill., Aug. 19.

Cook Co., Ill., Aug. 19.

(The plant in question is the horsemint—Monarda punctata—and belongs to the large and important mint family, the members of which are usually aromatic and honey-producing. A goodly number of these plants bloom from July to November in sandy fields and dry banks, and furnish a rich supply of nectar for the bees during the drouth season. C. L. WATSON.)

Continued Drought.

No rain yet. We never experienced such a drought. Bees may gather in a month or two. E. T. FLAHOAN.

ST. CLAIR CO., Ill., Aug. 30.

Season in North Carolina—Dollar Queens.

This has been the wettest and driest season I ever saw. Up till July 1 it rained nearly all of the time. Then there was a drouth for nearly five weeks, so we have had a short honey season. The linden blossom commenced to open about July 4, and was very rich in nectar for about 15 or 20 days, then the buckwheat commenced to yield nectar, and was never better, until the rain cut it off, two weeks ago. It has rained nearly every day since. Some bees are in very good condition. I never saw better prospects for a full crop of honey, the fields and woodlands being covered with honey-yielding weeds. I have taken only about 100 pounds of fine honey up to date, mostly extracted. I will take more in September, if the weather is favorable.

I want to say a few words in regard to "dollar queens." In my opinion nothing else has done as much harm to the bee business as the sale of the dollar queen. The beekeepers are reared for the trade, not for business. A queen ought not only to be tested for purity, but for business in age and weight, and the queen sent with the bee hives. The queen-gatherers, before she is offered to the public for business. If each queen had a good guaranty for egg-laying, her bees would be for sale. They are needed in the east and west for honey-making, and the extra hardness for wintering. It would improve the bee business more than any other one thing. I say it in my opinion. Let us hear from some of our big beekeepers.

Langstroth on
The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Ghas. Dadant & Son.

guns in this respect. Don’t understand me to mean that there are no good queens—there is about one good one in 50, according to my experience. I have bought more than that number, and only one was of any value worth mentioning. Bees in a state of nature don’t have their queen bees but one season, for they fall by the wayside the first winter, as the limit-survive.

I have seen the bee-business for 25 years, and have learned some things, but there is much to learn yet. A. J. McRaito.

Watauga Co., N. C.

Too Dry for Honey-Production.

I think the American Bee Journal is splendid, and I don’t think I could do without it. We have but little honey in north Texas this year, as it has been too dry. I have 20 colonies, and will have to feed some of them.

Dallas Co., Tex., Aug. 28.

Mulberry Pulp for Bees.

Yes, as Dr. Miller says, page 550, “I would probably take a good deal to make old bee-keepers believe that bees could store good honey from the pulp of any fruit.”

Then, again, some of them would be sufficiently industrious and investigating, when, lo! they may learn that pulp from white mulberries, containing, as they do, 7% percent sugar, would reveal mysteries in honey-gathering that would astonish them!

We live in an age check full of surprises, and old bee-keepers may as well wake up to the fact before their children urge it upon their attention.

And as the experiment of planting a hundred cuttings of wild mulberry would be hardly a dollar, would not such a beloved seer in bee-lore—our esteemed Dr. Miller—do a worthy act to employ his benign influence in encouraging his readers at least to attempt a venture that at its worst would leave bee-keepers in possession of delightful shade-trees, serviceable timber, and delicious fruit?

I know that the best impulses of his good heart strongly tend in this direction, but years of observation have compelled sober discretion, even to timidity and distrust, I fear.

But let courage and hope reawake, faith also, lead on to untried but reasonable measures, trusting, thereby, to develop resources hitherto unknown. If this spirit possessing these qualities we owe most beneficent discoveries.

Dr. Piero.

Against Zine Honey-Boards.

It is not very often that I give my views on the methods of manipulating bees, but as each bee-man plods along the dusty road to fortune, if he sees, or thinks he sees, something in the shape of a mote in his brother’s eye, he forthwith proceeds to pluck it out, or at least feels he ought to do so.

I do not use honey-boxes. The queen has the liberty of the hive. I do not use them because they are in the way of the workers.

The field bee comes in heavily loaded, tired

Caught Seed Free!

We have a small quantity of Catnip Seed which we wish to offer our readers. Some consider catnip one of the greatest of honey-yielders. We will mail to one of our regular subscribers one ounce of the seed for sending us one New Subscriber to the American Bee Journal for a year with $1.00; or will mail to one of our regular subscribers one ounce of the seed and the American Bee Journal one year—both for $1.30; or will mail an ounce of the seed alone for 35 cents.

Address, John Y. Calahan, General Agent, 111 Adams St., Chicago.

Where the Nectar Comes From.

Prof. B. Shmelk says in Home and Flowers:
The nectar-glands are extremely variable in form, size, color, etc. In phlox it is the inner most surface of the slighly swelling at the very base of the tube of the corolla, in the columbine it is the surface of the innermost base of the spur on each of the five petals; in the larkspur, violet and Passiflora it is a part of the inner surface of the spur; in the barberry there are two orange-colored glands at the base of each of the inner petals, etc. In some cases the nectar is produced in such quantities that it can readily be tasted. Nectar-glands, however, are not always conspicuous, indeed as a rule they are more or less concealed, and other means must be employed first to secure the attention of the insect. This is most commonly done by special odors and by color. Very often both color and odor attract insects, as in roses, lilac, etc., but the buckthorn, mignonette and other inconspicuous flowers secure recognition chiefly by their color.

Bee Keeping as a Sole Business.

One of the questions likely to occur to every young bee-keeper who has made a substantial success with a few colonies of bees may be worded in some such terms as the following: “Can I make a good living at bee-keeping alone?” Or “If this account comes very frequently the question as to what may be depended upon as the average yield or profit from a single colony of bees, or the question, How many colonies of bees shall I need so that I may depend upon them alone for a living?”—questions which no man living can answer definitely.

C. Davenport gives the matter some discussion in the American Bee Journal, and settles the question as to whether one can make a living at bee-keeping alone by saying he has done it. But he says his is a good locality, and that he has no wife or family to support and adds, “While I would not advise a young man to take up bee-keeping as a life work, in my opinion there is no question but that a

DESKS FOR GENTLEMEN AND LADIES!

These DESKS are made of quarter-sawn oak, first-class finish, well put together, and will please every purchaser. They are an ornament to any home, as well as being a useful necessity. Would make a FINE GIFT for father, mother or sister.

The Combination Desk and Book Case

is just the thing for a farmer or business man of any kind. to keep his private papers in, and for his books, etc. The drawers have locks, and there are a number of pigeon-holes inside each of the desks shown herewith.

Size, 40 in. high, 25 in. wide, 15½ in. deep.
Price, $2.85.

The above firm is entirely reliable.—EDITOR.
The "Barler Ideal" Oil-Heater....

Saves Its Cost Every Year! NO ODOR! NO SMOKE! NO ASHES! Costs only a cent an hour to run it.

The editor of the American Bee Journal is using the "Barler Ideal" Oil-Heater, and it is all right in every way. We liked it so well that we wanted our readers to have it too, so we have recently arranged with its manufacturers to fill our orders. The picture shown herewith is the one we recommend for general use. It is a perfect gem of a stove for heating dining-rooms, bed-rooms, and bath-rooms. It hinges back in a substantial way, and is thereby well made tight round. The uarm removes for heating water. The brass font, or well, has a ball, and holds nearly one gallon of kerosene oil. It is just as safe as an ordinary lamp. You wouldn't be without it for twice its cost, after once having one of these stoves. Most oil-stoves emit an offensive odor, but this one doesn't. Its height is 29 1/2 feet, and weighs 20 pounds, or 30 pounds crated ready for shipment, either by freight or express.

Price, f.o.b. Chicago, $6.50; or, combined with a year's subscription to the American Bee Journal—both only $6.50. FULL DIRECTIONS GO WITH EACH STOVE.

If you want something that is really serviceable, reliable, and thoroughly comfortable, you should get this "Barler Ideal" Oil-Stove, as it can be easily carried by any woman from one room to another, and thus have all the best you want right where you want it.

Address, GEORGE W. YORk & CO., Chicago, Ill.

A HANDY TOOL-HOLDER!

Sent by Express, for $1.50; or with the Bee Journal one year—both for $2.00.

Every Manufacturer, Miller, Carpenter, Cabinet Maker, Machinist, Wheelwright and Quarryman, Farmer, or any one using a grinding-stone, should have one of these Tool- Holders. One boy can do the work of two persons, and grind much faster, easier and with perfect accuracy. Will hold any kind of tool, from the smallest chisel to a draw shave or ax. Extra attachment for sharpening any style blades included in the above price. The work is done without wetting the hands or soiling the clothes, as the water flows from the operator. It can be attached to any size stone for hand or steam power. Is always ready for use, as nothing to get out of order, and is absolutely worth 300 times its cost.

No farm is well-equipped unless it has a Tool-Holder. Pays for itself in a short time.

How to Use the Holder.

DIRECTIONS.—The Tool is fastened securely in the Holder by a set-screw and can be ground to any desired bevel by inserting the arm of the Holder into a higher or lower notch of the standard. While turning the crank round to the right hand, the left hand on an end of the tool will move toward or away from the stone, or examined while grinding, as readily and in the same way as if held in the hands.

For grinding Round-Edge Tools, the holes in the stand are used instead of the notchs.

A Foster Stylographic Pen....

This pen consists of a hard rubber holder, tapering to a round point, and writes as smoothly and cleanly as a steel pen. The point and needle of the pen are made of platinum, alloyed with gold, and the nib will retain its great durability which are not affected by the action of any kind of ink.

They hold sufficient ink to write 10,000 words, and do not leak or blot.

As they make a line of uniform width at all times they are unrequired for ruling purposes.

Pens are furnished in neat paper boxes. Each pen is accompanied with full directions, filler and cleaner.

Best MANUFACTURING Pen on the MARKET.

19,000 Postmasters use this kind of a pen. The Editor of the American Bee Journal uses the "Foster", You should have one also.

Rocky Mountain Bee-Plant Seed! (Cleanse intestines...) FREE as a PREMIUM.

The A B C of Bee-Culture says it: "This is beefed, or the plant it grows in the garden, and says nothing of the honey it produces. It grows from the same seed as clover, and clusters large, clusters of bright pink flowers. It grows naturally on the Rocky Mountains, and in Colorado, and it is also valuable for honey." We have a few pounds of this Chinone seed, and offer to mail a 1-pound package as a PREMIUM for sending as ONENEW subscriber to the American Bee Journal, with $1.00 or $5 pound by mail for 40 cents.

Please mention Bee Journal when writing advertisers.

FREE as a Premium

A Foster Stylographic Pen....
alent of five frames of brood and bees. Four or five days later put on an upper story on each alternative hive of the class of colonies from which you removed a queen, alternating the frames of brood and bees, both in the lower and upper story, and there will be no fighting. If your hives are standing close in pairs, nearly all your swarms will remain until you put them. At this time I would introduce a young laying queen to each of these double colonies. Let them thus remain until most of the brood is hatched. When the time for swarms arrives contract the brood-chamber to five frames, and use the frames of brood and weak colonies in filling up such spaces. Such colonies will do well in working up the season.

But to return to the second weaker colonies from which we drew our batch of brood. This class of colonies has each a second-class queen, a little patch of brood, and some field-bees. What shall we do with them? Let them alone until the time you expect your best colonies to swarm. At this time I would draw frames of brood from each colony likely to swarm, contract the brood-chamber to five frames, and use the frames of brood and weak colonies in filling up such spaces. Such colonies will do well in working up the season.

SWEET CLOVER
And Several Other Clover Seeds.

GEORGE W. YORK & CO., 144 & 146 Erie Street, CHICAGO, ILL.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Aug. 22.—White comb brings 15¢ per pound for the choice grades, with other lines of comb fetching 10¢. Clover honey at 15¢; dark, 10¢. Extracted, fair dinner honey at 15¢; dark, 10¢. Extracted, fancy dinner honey at 20¢—good, 26¢; choice, 30¢. Beehives steady at 30¢ for choice yellow. R. A. BURNETT & CO.

CINCINNATI, Aug. 10.—The honey market is running dull on account of many hives having been torn and removed. Extracted sells only to manufacturers from September grades, 60¢ per pound; dark, 65¢; white, 60¢; white clover honey from 80¢ to 85¢. Fancy white clover hives from 90¢ to 1.00.

R. C. WEBER.

BOSTON, Aug. 19.—Our market to-day is about 1600¢ for fancy; A No. 1, 150¢; A No. 1, 140¢. Honeys, light, 75¢; dark, 80¢.

Several lots of new Vermont honey in carlots have thus far been received, meeting a ready sale at 15¢, although of comparatively fair quality. The trade generally seems disposed to hold off, if at all, for larger receipts. R. J. Foster.

OMAHA, Aug. 8.—New comb honey is arriving by express in small quantities from Iowa and Colorado, and selling at 25¢ per case in a retail way. California extractors and dealers are offering carlots at 45¢ per pound, f.o.b. Cal.-Iowa, and are quoting 50¢ per pound. Further shipments of any sales having been made thus far. The demand for and price of clover comb are steady in this market, large this year in Colorado, Utah and California.

PICKY BROS.

NEW YORK, Aug. 7.—There is some demand for new crop of comb honey, and prices are quite numerous for this time of the year. They are generally 55¢, 60¢ and 65¢ per pound, f.o.b. New York, and prices are now beginning to receive shipments from New York State and other states. Fancy: honey, white, 15¢; No. 1 white, 130–140¢; amber, 110–120¢. No new buckwheat is on the market as yet, and sales do not expect any before next month. Prices are steady.

EXTRACTED is decidedly dull. Plenty offerings, with a limited demand. Although the prices are rather nominal. We are selling at 75¢ per pound. We quote fancy, white, at 15¢, dark, 10¢. We quote California, 90¢ per pound. We are selling fancy at 85¢ per pound. Beehives dull declining; for the present we quote 25¢.

PICKER BROS.

DES MOINES, Aug. 7.—There is very little doing here in new crop of honey. Some small lots are now being produced comb honey on the market, and selling in a retail way at $3.50 per pound. We do not look for much trade in this region for the future. We quote: comb honey, 80¢, 90¢ and 100¢ as a rule.

BUFFALO, Aug. 10.—Quite a good demand for fancy honey, 160¢, and lower grades, 120¢; old neglected. Advise moderate shipments only of fancy, as $1.00 as a rule. We advise manufacturers to hold on to their stock as long as possible.

SAN FRANCISCO, Aug. 14.—White comb, 115–125 cents; amber, 88–90 cents; dark, 60–70c. Extracted, white, 55–60¢; light amber, 45–50¢; amber, 60–70¢; dark, 55–60¢. Market continues quiet, with apiculturists, as a rule, unwilling to admit at prices generally named by wholesale operators. Quotations represent as nearly as possible the prices in the market at this date for round lots, although free sales could not probably be effected at full figures, while the other hives as a rule are not quoted but are being realized in the filling of some small orders.

KANSAS CITY, Aug. 6.—Some very fine Missouri honey is now on the market, selling at 100c per pound for white flower comb honey, and Utah shippers are offering new comb honey in carlots for first half of August, shipment to take place in carlots on No. 2, f.o.b. shipping-point. The market for extracted honey is yet rather unsettled, as prices ranging from 94–95¢, f.o.b. shipping-point, seem to be rather a matter to make contracts. PICKER BROS.

—By—
PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thou-
sand—$1.25 postpaid.

A description of the book here is quite unneces-
-sary—it is simply the most complete scientific
and practical bee-book published to-day. Fully
illustrated, and all written in the most fascinat-
ing style. The author is also too well-known to
the whole bee-world to require any introduction.
No bee-keeper is fully equipped, or his library
complete, without THE BEE-KEEPERS' GUIDE.

This 16th and latest edition of Prof. Cook's
magnificent book of 460 pages, in neat and sub-
stantial cloth binding, we propose to give away
to our present subscribers, for the work of get-
ing NEW subscribers for the American Bee
Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT sub-
scribers only, and no premium is also given to
the TWO new subscribers—simply the Bee Jour-
nal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee
Journal (with $0.50), and we will mail you a copy
of Prof. Cook's book FREE as a premium.
Prof. Cook's book alone sent for $1.25, or we club
it with the Bee Journal for a year—both for only
$1.75. But nobody anybody can get only TWO
new subscribers to the Bee Journal for a year,
and thus get the book as a premium. Let every
body try for it. Will YOU have one?

GEORGE W. YORK & CO.,
144 & 146 Erie Street,
CHICAGO, I11.

24th Year Dadant's Foundation. Year

We guarantee
satisfaction. (*) (*)
What more can anybody do? BEAUTY, 
PURITY, FIRMNESS, No SAGGING, No
1.055.
PATENT WEED PROCESS SHEETING.

Why does it sell
so well? (*) (*)
Because it has always given better satis-
faction than any other.
Because it has not been any complaints, but thousands of compli-
ments.

Send name for our Catalog, Samples of Foundation and Veil Material. We sell the best Veils, cotton or silk.

BEE-KEEPERS' SUPPLIES OF ALL KINDS.

Very fine pure-bred BARRED PLYMOUTH ROCK Chickens and Eggs
for sale at very low prices.

Langstroth on the Honey-Bee—Revised,
The classic in Bee-Culture—Price, $1.25, by mail.

Beeswax wanted at all times.

CHAS. DADANT & SON, Hamilton, Hancock Co., III.

Please mention Bee Journal when writing.

ANOTHER ENDORSEMENT
FOR Root's Red Clover Queens

ALEXANDRIA, IND., Aug. 1, 1901.

THE A. I. ROOT CO., Medina, Ohio.

Dear Friends:—The tested clover queen came in good condi-
tion and has filled seven frames with brood two weeks from
the day she arrived, which is better than the combined efforts of three
"yellow" queens purchased two years ago. I believe she is going
to be the counterpart of the queen purchased of you in 1896, in
which case money could not buy her.

Yours Fraternally,
EVAN E. EDWARDS.

PRICES OF RED CLOVER QUEENS:

Gleanings in Bee-Culture one year and Untested Queen ....$2.00
" " " " " " Tested Queen ...... 4.00
" " " " " " Select Tested Queen. 6.00

If you want something good you can not do better than to order one of these queens. All orders are filled promptly. No extra postage on these to foreign countries.

THE A. I. ROOT CO., Medina, Ohio.

GEORGE W. YORK & CO. 144 & 146 Erie Street,
CHICAGO, I11.

are headquarters for ROOT'S BEE-KEEPERS' SUPPLIES IN CHICAGO.
Send to them for their free Catalog.
25 cents Cash paid for Beeswax.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

This is a good time to send in your Beeswax. We are paying 25 cents a pound—CASH—for best yellow, upon its receipt, or 27 cents in trade. Impure wax not taken at any price.

Address as follows, very plainly,

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

H. M. MELBEE, HONEYVILLE, O.

This is the full size of the knife.

Your Name on the knife. —When ordering, be sure to say just what name and address you wish put on the knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-stone, and we warrant every blade. The moulds are made of German silver, and will never rust or corrode. The rivets are hand-forged German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel; and the finish of the handle as described above. It will last a lifetime, with proper wear.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return; otherwise it cannot destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your Pocket-Knife will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to get this Valuable Knife. — We send it postpaid for $1.25, or give it as a Premium to the one sending us three New Subscribers to the Bee Journal (with $1.90). We will club the Novelty Knife and the Bee Journal for one year, both for $1.90.

GEORGE W. YORK & CO.
St. Chicago, Ill.

#* Please allow about two weeks for your order to be filled.
Discouragings and Encouragements in Queen-Rearing.—Never before was so much said and taught about improvement of stock, and as a consequence about queen-rearing. In probably the great majority of cases little or nothing is done to control in any way the actions of the bees in the rearing of queens, beyond the occasional introduction of a queen from elsewhere, with the hope of improvement.

Even those who are willing to do all in their power to make improvement are hand-rapped as in no other line of breeding, by the lack of control of the sire in mating. The man who attempts to breed a good horse or cow can do just as much toward controlling the sire as the dam, while the bee-keeper may take all the pains possible to select the dam and then have her meet a mate of the poorest sort from some colony two miles away. To be sure, he may succeed to a degree by having his young queens fly out to mate at a time of day when drones in general are not flying, or he may go to the expense of having a Davit cage, but even then the control is only partial, for instead of a single drone being selected, a hundred or more will be on the scene of action.

But with all the discouragements there is much to encourage, and a man with the smallest allowance of ability and experience could do something, if not to improve his stock, at least to keep it from becoming worse. For, left entirely to itself, the greatest amount of increase coming from colonies most given to swarming and least given to storing, the chances are more in favor of deterioration than improvement. By purchasing a single queen for Italian blood, the owner of black bees may, inside of two months, have all his workers changed at least to half-bloods. No such rapid change can be made in any other kind of stock, so, in spite of discouragements, in this one respect the bee-keeper has the advantage over breeders of other stock.

While the discouraging fact is emphasized constantly that inferior drones within two miles or more may make trouble, the converse of this should not be forgotten. If for the inferior drones of a neighbor lower one's chances for improvement, it is also true that one's own superior drones will steadily be raising the grade of the neighbor's bees, so that as the years go by the damage from outside drones will be less and less.

Locality or Kind of Bees?—Those who write for beginners in bee-culture need not expect that their writings will be scouted only by those without experience. Witness some of the following questions:

Some of the teachings of J. D. Gehring, when considered in the light of my own experience, are somewhat puzzling. An instance occurs on page 356. The first item given in the line of winter preparation is to look in the hives about the middle of October to ascertain the fact that the colony has a queen. Rap sharply a few times on the outside of the hive, to make sure that there are no bees within to fill themselves, then take off cover, give a little smoke, and then proceed with the search for the queen. Now in my experience I should expect a rather long search after treating the bees in that way. In the first place, there is no question about the first thing I should do after rapping sharply a few times on the outside of the hive would be to take to my heels if I didn't want a lot of cross bees about my ears. Perhaps, however, Mr. Gehring smokes before he runs. He doesn't say. In any case, if I should rap on the hive enough to make the bees fill themselves and then should give a little smoke, my bees would be ready to run like a flock of sheep, making the chance for finding a queen about as great as some would ask, Is there a difference in bees that makes Mr. Gehring's bees hold still when mine would be sure to run?

Also, what is the object of finding the queen, seeing that it makes no difference in the treatment? For he doesn't say a word about doing anything different with a colony if the queen should not be found.

OLD ENGLISH.

There is a good deal of difference in bees in their deportment under the same kind of treatment. An amount of smoke or jarring that would have very little effect upon some bees would make others run so that the task of finding a queen would be difficult, if not impossible. The object of ascertaining the presence of a queen is no doubt so that a queen may be furnished where needed, or the queenless colony united with another. It is doubtful, however, that the practice of beekeepers in general would agree with that of Mr. Gehring. When looking for a queen it is of first importance that the bees should be smoked or disturbed in any way as little as possible. Once the bees get to running it is better to give up the search till another time.

A single puff at the entrance, before opening the hive, and a very little smoke over the tops of the frames after the cover is removed, will be sufficient to keep the bees from flying out at the operator, and that is all that is required. Indeed, with some bees no smoke at all is necessary, and all jarring of the hive should be carefully avoided.

Probably few beekeepers make a practice of looking through the hives for queens in the fall. If there is young brood in the hive the presence of the queen is known without seeing her. If no brood is present, which is often the case, the bees may be for and very hard to find. Not finding her is by no means positive proof that there is no queen: so if no queen is found, and another queen is given, there is a fair chance that a queen is thereby wasted. On the whole, it is not likely that many would consider it advisable to make the search.

Getting Bees Off the Comb is rated by Editor Hutchinson as the most disagreeable part of producing extracted honey. He gives the practice of Mr. Miller, a Canadian, as follows:

Give the bees a good smoking, which drives down most of them, then get the super down near the entrance, when the rest of the bees will leave the super for the hive. When most or all of the bees are taken off, use the escape. Mr. Hutchinson says he uses the same plan in removing surplus comb honey.

Dr. C. C. Miller uses somewhat the same plan. He writes:

"When a super of sections is to be removed from the hive, the plan of procedure depends upon whether the robbing tendency is not. During the height of the season, and until the flow wanes, there is usually no trouble from robbers, and super or sections may often be left exposed for an hour or more without any danger. Still, there is always a possible danger, and a close watch must be kept if after the cover is replaced the super is set endwise upon it, well forward, with one edge of the super projecting over a little. After a time the bees will start a line of march from this projecting part down to the entrance of the hive, and not many bees will be left. It is possible that there would be an advantage in setting the super close down against the entrance, but when it is on the top of the hive it is easy to keep watch of it from any part of the apiary, as so to see the first attempt at robbing, whereas a land-office business might be going on unseen if a super stood on the ground.

"After the bees are mostly out of the super, they are stacked up in a pile until the pile contains perhaps a dozen, a robber-cloth escape being used to cover the pile from the time it is started. This escape is simply a robber-cloth having in its center a very
large core escape of wire-cloth. It ought hardly to be called a core escape, for instead of being a cone it is a pyramid, each side of the pyramid being an equilateral triangle, and each side of the triangle measuring 10 or 11 inches. This allows the light on top to pass through, but the remaining bees make their way out with no danger of robbers entering. If robbers are troublesome, then the supers are taken immediately from the hive (a little more smoke being used than usual), and put directly on the pile under the escape. The robbers may be in thick clusters at the base of the escape, but they do not seem to know enough to enter at the top. And yet, after second thought, we felt it was an opportunity for us to enlighten him in a kindly manner, which we felt sure he would appreciate, for even editor's have much to learn, especially young ones.

Now, after having said that much, we will go further, and say that we wish the Rocky Mountain Bee Journal all kinds of success in the very difficult field in which it has chosen to enter.

But we would also like to suggest, that sometimes it is better to write privately to a supposedly offending brother, and see if with his help a rather ridiculous side-show of one's self can not be avoided.

Rather Serious Accusations against the editor of the American Bee Journal are contained in the following paragraph from the Rocky Mountain Bee Journal:

Under the head of "Contributed Articles" the American Bee Journal recently published Mr. W. L. Porter's paper on "Co-operation," which appeared originally in the June issue of the Rocky Mountain Bee Journal.

As Porter's article was not credited to the R. M. B. J., and appeared as original correspondence to the same, we may say that this is the republication of articles from the R. M. B. J., but we do insist most strenuously that proper credit be given to the editor. Porter has never mentioned the existence of the R. M. B. J., and it would seem that to carry his policy of unfriendliness toward Western bee-journals to the extreme limit.

Editor York deems it legitimate to take from their columns and mention in his paper without giving credit. Whatever may be the motive, this is a species of piracy rounded coincidently by all reputable journalists, and we are sorry to see it indulged by a member of the apiarian press. All we ask is, treat us fairly, Mr. York, or hands off, please.

We haven't read anything in a long time that has amused us so much as the above. And yet we do feel a bit sorry for our new brother editor. He didn't notice that right at the head of the article in question we had this credit:

"Read at the Longmont meeting of the Colorado State Bee-keepers' Association, April 30, 1901, by W. L. Porter."

You see, we did not publish it "as original correspondence in the A. B. J.," as he charges. No other credit than what we gave was needed. Of course, our good brother editor didn't know that anything read at a convention is public property—even the report of discussions is also, unless the journal publishing it has paid for such report, as we have done for that of the National Bee-Keepers' Association.

So it is clearly seen that Mr. Porter's article wasn't even written originally for the Rocky Mountain Bee Journal, but for the Colorado State convention. If it had been written especially for that paper, why was it necessary to read it at head these words when appearing there also?

"A paper read at the Longmont meeting of the Colorado State Bee-keepers' Ass'n., April 30, 1901:"

Again, our worthy fellow editor says this:

"So far as we are aware, the A. B. J. has never mentioned the existence of the R. M. B. J. etc.

Of course, again he wasn't "aware," for he evidently did not know of the following notice, which we printed on page 212 of this journal for April 4, 1901:

"The Rocky Mountain Bee Journal is the name of the latest claimant to the patronage of the bee-keeping public. It purports to be published "For Colorado and the Great Inter-Mountain Region." It is to be issued monthly, is neatly printed, and presents a good general appearance."

Our first inclination, upon reading the accusations made by our fellow editor was to remove them entirely, as they deserved to be treated. And yet, after second thought, we felt it was an opportunity for us to enlighten him in a kindly manner, which we felt sure he would appreciate, for even editor's have much to learn, especially young ones.

W. Z. Hutcinson.

THE EXECUTIVE COMMITTEE OF THE NATIONAL BEE-KEEPERS' ASSOCIATION FOR 1902, ELECTED AT BUFFALO LAST WEEK, ARE AS FOLLOWS:

President—W. Z. Hutchinson, of Michigan.
Vice-President—O. L. Hershiser, of New York.
Secretary—Dr. A. R. Mason, of Ohio.

THE ROOF-APIARY OF AUGUST ASMUSSEN, of Pottawattamie Co., Iowa, helps us out our first page this month, and that's what he wrote about himself and his bees:

Editor American Bee Journal:—Ten years ago I started with one colony of bees, and, finding it both pleasant and profitable, I have kept bees ever since.

I am a harness-maker by trade, and since last spring have lived on the main street next to my shop. In order to care for the bees properly I decided to keep them on the roof, and I was forced to move them at night, as the citizens strongly objected to keeping them in town.

If it were not for the swarming habit of the bee, no one would have known the bees were there. I have prevented the escape of good swarming, to a great extent, by giving them plenty of room, and controlling them by clipping the queen's wings. The bees did well during the month of June, but on account of lack of rain during July they decreased in number increased, judging by the hive on the scales.

AUGUST ASMUSSEN.

Mr. W. D. DUNGAN, of Dupage Co., Ill., began in the spring with 10 colonies, now has 15, and will likely harvest 100 pounds of comb honey per colony, spring and fall, and will have a hive in each region. Mr. Dungan combines bee-keeping with the office of Justice of the Peace, and it seems to be a good arrangement.

We had the pleasure of visiting Mr. Duncan and his apiary, Aug. 29. He lives 17 miles southwest of Chicago, in a fairly good sweet clover district, so his honey is mainly from that source. He will have no difficulty in selling all he can take off the hives at $3.50 a frame. He is the Danzenbaker hive, but expects hereafter to use the regular Langstroth 10-frame brood-chamber with Danzenbaker super. Some other bee-keepers find such a combination all right for the production of comb honey. One great advantage is that in buying or selling bees, there is no difficulty about free-handled and willer-wender frames. As the Langstroth size is practically standard. And, then, a few Danzenbaker frame is too shallow for safe wintering of bees in a cold climate.

Mr. Duncan has a very neat apiary. But, then, if you knew the man you would expect that. He lives in a neat and pretty town. It is a pleasant town, too. He has not had a case on his court docket for months. Very likely one cause of this happy condition of affairs is "no saloon." The people in that beautiful Chicago suburb have better sense than to tolerate the presence of that pest-hole.

Mr. Duncan took us to see several other near-by apiaries, in one of which (the elder Mr. Schramm's) was a colony in a straw-skep—the first occupied skep that we had ever seen. Mr. S. said he got nothing but swarms from it, but this year he has not had even that from it, though it was a powerful colony. It is a novel and interesting sight.

About 3 p.m. Mr. D. ordered up a good horse and buggy, and took Mrs. Duncan along, to visit Mr. G. W. Stephenson's apiary, about three miles away. We found Mr. S., at home with his nearly 40 colonies of bees. He also gets a skep to house an average of 150 pounds of comb honey per colony, spring count which was 60 colonies. Mr. Stephenson only knows of one that produces a good crop of honey every year, but all the sections are always uniformly filled. Perhaps one reason why he secures such good results is because he has strong colonies in 10-frame Langstroth hives, and only 24 bee-way sections in the regular 8-frame section. The super, leaving a large open space at each side to be filled with bees. In this way the outside rows of sections are sometimes sealed over first, and all are as evenly filled as could be desired. To hold the sections in the super he has a 31-inch follower board, and, as the space at the opposite end also. Mr. Stephenson is well satisfied with this arrangement, as he well may be, for with its use he gets the results he wants.

W. Z. HUTCHINSON.
Contributed Articles.

A Bee-Keeper's Vacation Spent in Wisconsin.

BY C. P. DADANT.

T is a nice thing to take a vacation if one can find the time and opportunity, but one must feel that nothing left behind will suffer from his absence, and that the trip would not be absolutely needed for some indispensable purpose. When you can combine these requirements, it is easy to figure, on the other hand, how much health and prolongation of life you can secure by a short absence from the daily routine.

My father is subject to hay-fever—a dreaded complaint with which probably a number of my readers are acquainted. This disease, it is a sort of asthma or catarrh, caused mainly by the pollen of the ragweed. The hay-fever sufferers of the United States are not quantitatively the stubbles, together with the knot-weed, and Spanish-nedles, (which by the way, yield considerable honey), most of the growth of those weeds taking place after harvest. But in the vicinity of the Great Lakes, up in northern Wisconśnie, the small grains—wheat, oats, rye and barley—grow so slowly, and ripen so late, that there is not time for any plant like these to grow, bloom, and ripen their seed, after harvest. So Sturgeon Bay is immune, and it is that point to which I have selected for my annual anti-hay-fever. For 14 years he has regularly spent six or seven weeks there, in August and September, returning home by the end of the latter month.

If the reader will hunt up the map of Wisconsin, I will point to him the pretty spot of which I am about to speak. I do not enjoy reading of a place unless I can "place" it on the map, and I take it that others are like me in this respect.

If you have the map, start with your finger on Lake Michigan, from Chicago northward. You will soon come to the peninsula which forms Door County, Wis., and which separates the waters of Lake Michigan from those of Green Bay. About half way along this peninsula you will notice a narrow neck of land, with a little bay indenting the shore of Green Bay. This is Sturgeon Bay. At this point the neck of land is only 1 1/2 miles in width and a deep canal has been cut in the land, joining the two lakes, so that the boats that go from Chicago to Green Bay can enter Marinette, Menominee, and Escanaba, are no longer compelled to go up to the point and run down again, passing at the north end, through what is called "Death's Door," (an ugly name), but you run from Lake Michigan through the Sturgeon Bay canal into Green Bay, and vice versa, saving an extra trip of a hundred miles or so, and the peninsula has practically become an island.

The city of Sturgeon Bay, on the bay of the same name, is supplied by water Lake Michigan, the side and Green Bay on the other. The air is pure and cool, always refreshed by lake breezes coming from either side, and our Illinois, Iowa and Missouri friends must really read and get a treat of what that pure air can do to the parched, dusty plains and overheated fields, roasted by the August sun, and reach an oasis where everything is green and fresh, where mosses and ferns grow all over the forest and form a green carpet under your feet; where the water is enough, and when no one is considered high when it reaches 80 degrees in the shade.

Well, business was dull at home, the bees were idle, the small clover honey crop harvested, and our boys were willing to undertake to do all that had to be done, and take from our shoulders the home responsibilities. So wife and I accompanied "Grandpa" Dadant on his usual trip.

The city of Sturgeon Bay is not a fashionable resort. It is a plain, every-day looking little town of 3,000 inhabi-

tants, with plenty of grit and lots of "go." The folks are not spoiled by rich tourists, and are willing to accept reasonable sums for entertaining the confiding visitor whose pockets are not overflowing with dollars. Fish is plenty, and the water is clear; yes, as clear as that of Lake Genuva, Switzerland; but we miss the snow-capped peaks that form the back-ground in that beautiful spot.

I found four bee-keepers, two of whom are subscribers of the American Bee Journal, and all seemed well pleased with their bees and the crops they harvest. One of them lives right in the city, and has an apiary of 59 colonies. He is employed as a skilled mechanic in one of the large sawmills of the town, but was unoccupied just at the time, as the mill had closed for a few days. We visited him one evening and found that he follows our plan of running the bees for extracted honey, with large benefit.

"This is the only way in which I can keep bees and make it pay, and still continue at my work," said he. "I could not expect to run a large apiary and leave to my wife the care of harvesting the swarms, and following the bees in the harvest of a crop of comb honey, while, by using extracting supers, I can be away from home all day and feel sure that the swarms will be few, and that the bees are supplied with plenty of room; and it takes but a short time to harvest the crop, when the bees are through with honey-gathering. This is certainly the best method of bee-keeping for a man who is away from his home most of the time."

The honey resources seem to be very similar to ours. White clover is the main crop, but it seems to come later, as wheat does. When we were there, the crop was just over, and but little more honey was expected, and this only from fall bloom which, they say, rather irregular. Yet there is an abundance of weeds, and the climate seems mild enough to keep moisture in the ground at all times, for the woods are full of ferns, mosses, and plants that can only live in moist ground. But it seems so queer to us Illinois farmers, to see the amount of labor involved in clearing a piece of ground. After the brush has been either grubbed off or burned off, the big stumps from the ancient pines have still to be extirpated, and, after that, the stones must be carried out. These are usually made into fences, as in New England, and when one of them is too large to be removed, others are piled up on top of it, and stone heaps like this loom up in every direction. Many Swedes and Norwegians have settled here, and have very neat farms, and the women work out-of-doors about as regularly as the men.

At the point of land formed by the junction of Green Bay with Sturgeon Bay, the United States government has established a lighthouse on the edge of a fine grove, and near to the finest fishing grounds in the country. This spot is called "Idlewild," and on the shore of Green Bay almost under the light-house is a projecting ledge of rock, called, "Lover's Leap." I do not know whether or not this name is connected with any Indian adventure. There are so many "Lover's Leaps" in the country that this may not have any very authentic legend, but it is a romantic spot.

Together with a half dozen friends, we visited this spot and...
implant his good qualities in his offspring, but because of his speed.

If I were a queen-breed I would promptly send $25 for a queen whose bees had a tongue-reach of 21 100 of an inch; nor would I be afraid of any one applying a $10 "pressure" to the head of a bee from a 18 queen to make the latter a $25 queen.

Her very good, as at least three of our bee-editors are friends. I wish they were all friendly enough not to "spat" so much. Unless a better feeling is cultivated, our co-operative efforts will never amount to a "row of pins."

Farmers' organizations go to pieces because they doubt each other. Bee-keepers' organizations would do better if they did not accuse each other of misrepresentation and deceptive practice.

After having said all of this, I know of no three gentlemen that I have more confidence in than E. K. Root, G. M. Doolittle, and H. E. Hill, Massac Co., Ill.

(Continued on page 505.)

WITH the permission of the editor I wish to consider the criticisms by Wm. M. Whitney (page 405) of my article on page 311.

I stated therein that, judging from her rule of action, the honey-bee could not rule by the "beef and mutton" system. Instead, her ways were harsh and unyielding, and that she is never turned from her given course by that most beautiful qualification-love. It will be remembered that this was said in connection with a plan given for the introduction of "love-bees," as Mrs. Root says, because she had a great belief of the correctness of this deduction; for if the bees do have love for one another their love is of such form as to necessitate its being called by another name from that which makes men and women divest the cold, heartless methods — the iron methods — of a colony of bees, with the principles of true love as revealed in Christ, or with the basic principles of truly christian government, he assumed a wonderful stretch of all that he did to make extremes meet.

Mr. Whitney was pleased to call particular attention to the fact that "Christian governments provide for the unfortunate and infirm," and then says further, "but the time was when such persons were disposed of in the most contemptuous manner possible, and without the slightest regard for the good of the majority," just as the bees do now.

If it be true that the honey-bee "knows from instinct" how to manage her affairs, then why need any one expect to see her decrees mingled with mercy for the needy and the afflicted, if their requirements run counter to those interests or conditions that give the greatest freedom to perpetuate the existence of the colony?"

But, the love of country is selfishness, pure and simple, for the bee well knows that she can not exist alone in the world. This is possible for her only in swarms, and is best in large swarms; hence is her "devotion" and "patriotism" laid bare.

The real complexion of the honey-bee's nature must be admired and accepted by us, as it stands squarely at the facts, and note that all her acts of kindness are directed to that end which tends to promote the greatest individual security through the strength of the colony; also, upon the other hand, that the honey-bee invariably follows the sordid routine of utter disregard of the sufferings of the worthy though afflicted members of the colony, is it not a logical conclusion that no ties of love or bonds of sympathy exist between or among them?"

The fact that the honey-bee tenderly cares for her young simply argues nothing to the point Mr. Whitney seeks to gain. If it were love and not avarice that prompts her to do this, then in time of famine she would not keep back the hard won honey from those who were her "true friends" — that is, those who would not starve. But, if she would tear them from the cells and consume them. In more prosperous times we catch another view of the bee's "devotional" nature. The larval bee that is cared for so tenderly till it emerges from the cell is at once banished

Co-operative Effort Among Bee-Keeper. By W. T. Stephenson.

TRUSTS are the order of the day. Almost every line of industry, except farming and bee-keeping, is beingtrusted. Why not these?

Not long since some one writing on this subject gave the exact reason why farmers' organizations did not succeed, that each farmer, even on the very best of farms, are afraid to risk their commodities in the hands of a representative, even though they would get a higher price. Let us, as bee-keepers, be careful lest we join their grousing; for the result of our actions may be to make extremes meet.

So much for a preamble; now to the point.

I was greatly surprised when I read the article by Mr. G. M. Doolittle in a recent issue of the American Bee Journal. I was not so much surprised at the stand he took, as at the manner in which it was written. He says he is going to call a halt, and proceeds to accuse E. K. Root — the man who holds the highest and most responsible position among American bee-keepers — of misrepresentation, instead of in the ranks of the long-tongue advocates, as Mr. D. has done.

If Mr. Doolittle had been the fortunate possessor of that $290 queen, it is more than likely that that article would not have appeared, as it would have been to his interest to keep mum.

We are led to think that Mr. Doolittle hasn't been reading the bee-paper very yet; or he would know that he was not "first" to call a "halt." The editor of the American Bee-keeper thinks it deceptive to value an extraordinary breeding-queen at $50, $100, or $200, and to sell her daughters at $10, $15 and $25. Remember, Mr. Hill, that the fact that the queen is an alluring or an assassination, suppose you had a quantity of very deep jells filled with apples; wouldn't you be willing to pay a fancy price for boys with arms of extra length, if all of the apples they could reach were yours?

He asks if any one knows of an instance where fine stock sold for twenty times the price of the very best common stock. Not long since I read of a race-horse ("Flying Fox") selling for $40,000. It was not because he could
into outer darkness, if some physical defect unfit it for duty—a queen kind of love, indeed.

In the fourth paragraph Mr. Whitney virtually denies the correctness of his position by saying that the honey-bee is "governed by a law in Nature that means simply the survival of the fittest." Now what does the survival of the fittest mean in Nature but that the strong shall oppress the weak? This is exactly what I said was the rule of action with the honey-bee—that it's impelling power was greed and not love.

Mr. Whitney’s idea of love becomes “amusing” when he tells us to look to the bees for the “highest type of love and patriotism.”

Do Mr. Whitney favor a return to those primorval customs for the betterment of social conditions? We will be “gracious” enough to suppose that he does not.

There is at least a shadow of inconsistency in the exceptions Mr. W. has taken to those statements of mine. Referring as he says he does, that the honey-bee is governed by the law of survival, he seems to think otherwise. He has, for example, found that the queen-bee should be reared before the worker bees. Mr. Whitney seeks to ridicule my instructions for introducing a queen-bee by a method that is in perfect harmony with the law which he says governs the honey-bees. This he does not understand. He has no plan but to have a "experiment," and a "misfortune" to any who would dare to put it in practice.

Now the truth of the whole matter is, Mr. Whitney knows not where he is going, and is in serious doubt as to any credence to the practicality of introducing a queen-bee by running her in at the entrance of the hive as quickly as possible after taking her from the combs of another colony, but wishes to pursue the old-fogy method of caging the queen when introducing the stranger bees. This caging of the queen takes from her the bloom which is her greatest safe-guard in the midst of stranger bees.

The method I here advise using is so free from fussiness that I cannot see why any one should want to bother with a cage when introducing a queen-bee. All that is required to make it a success is, to take away the reigning queen and then thoroughly frighten the colony immediately and as quickly as possible. The honey-bee then will rise up, but let the colony realize for a moment that it is queenless, but get the stranger queens into its hive before she, too, realizes what is being done. Smoking the colony while pounding upon the hive to drive with some object is the most practical way of frightening the bees. This does not pervert the sense of smell so much as it diverts the attention of the bees till the queen has time to reach the combs. Then when the Misses Bees have wiped their mouths and turned about, Mrs. Bee is “at home” to them upon their own combs; and they don’t care a tinker what she smells like.

I do not advise introducing laying-queens into colonies having capped queen-cells. The queen can be introduced all right, Mr. Whitney notwithstanding; but too often the young queen is not able to hold her own and a laying queen has no chance in a fight with a virgin.

Let those who wish to try the method, use their more inferior queens first, till they become conversant with the realities. You can then introduce a stronger queen, and how much smoke and how much pounding upon the hive is necessary to insure the queen’s safety.

I believe that the readers of the American Bee Journal will not be long in learning the practical beauty of this quicker and better way of introducing a queen-bee.

Scioto Co., Ohio.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this Journal. You can aid much by sending in the names and addresses when writing us on other matters.
silkworm can not now exist without the aid of man, and if the canary bird is turned loose in its native country it perishes; for it is not adapted to the climate. It lived on a different plant here in Colorado. Then it traveled and took to potatoes, and now it is called the Colorado potato bug and no longer lives on its original food.

Mr. Pattee—I have one colony of pretty black stock. I knew the queen was changed three times by swarming. Yet the colony now is as black as it ever was. I have thought that perhaps the queens of this colony mated with their own drones.

II. Rauchfuss—I think that occurs very seldom. I once requeened a yard of 40 colonies with queens from one queen, and used that queen to furnish drones. Those drones should have been pure. But not more than one out of twenty of those queens were used, and there were not few colonies in the neighborhood, either, and they were not close by.

Pres. Aikin—To sum it up, select the best colonies, displaying vigor and other good qualities, and breed from them. This is the way Mr. Collins recommends. I have practiced the method of unqueening for years with hundreds of colonies, on whole apiaries at once, so that it made no difference about the bees mixing. The colonies retained their normal strength 21 days, and then they went down, and it only took three or four weeks for them to be materially reduced.

Mr. Gill—That may apply to whole apiaries, and yet a few individual colonies may be longer lived than others.

Mr. Harris—I offer the following resolution:

Resolved, That the Colorado State Bee-Keepers' Association recommends to its members, in buying queens, to buy only of queen-breeders who furnish pedigreed queens, mated by pedigreed drones.

Mr. Honnent—I am opposed to that resolution, not on account of the good it may do, but I know of so much as a registry for pure-bred queens. It may be a good thing for experiment purposes, but not common people into the hands of sharpers, who will advertise pedigreed queens, when there is no way to pedigree them.

Mr. Harris—You might change the phraseology and do good.

Mr. Pattee—Pedigrees of stock are brought up to higher excellence in that way.

Mr. Lyte—No one here has spoken of the National Queen-Breeders' Association. Any competent and honest queen-brededr can furnish the information. No one can be a member of the National Queen-Breeders' Association and be dishonest. I believe the resolution is in the right direction. I think we can get a pedigree of drones. I second the motion to adopt the resolution.

Rauchfuss—You can control fertilization. There are plenty of places here in Colorado where it can be controlled as surely as on an island. A man could go out a hundred miles on the prairie, and he absolutely sure that there were no colonies within reach but his own. Of course, he could not produce queens for a dollar a piece. He would have to feed.

Mr. Honnent—I am in favor of improving the breed. The question has been discussed by eminent breeders, and they agreed it was impossible to keep queens pure within a certain distance. But it won't be 30 days after you pass this resolution before you will see advertisements of pedigreed queens.

Mr. Large—We don't all practice what we preach.

Pres. Aikin—The resolution does not bind, it only recommends. The resolution was adopted.

THE RIGHTFUL SHARE IN BEE-KEEPING.

Question.—In working bees on shares, what shall the owner furnish, and what shall be the share of each—comb honey, extracted honey, and increase?

Mr. Harris—There is a great variation in the share one should have, owing to different conditions. The parties should fix that between themselves.

Mr. Foster—I have had a little experience in that line that was not altogether satisfactory. A year ago I gave 10 pound colonies each, or one colony for each person, to the owner. When the colony was above the average I gave $2.50 per pound. Last year I shared half and half all through, expenses and profits, and when I figured it up I found that I had paid the owner $20 per colony, and it was now my turn to cry over the swarms I had to buy.

Mrs. Brock—I have always leased on halves, and received half the honey and half the bees. It is a question with me how the honey should be divided. Should the lessee take his share as a plugger, or should both parties be there? The bees.

Mr. Dods—I have been leasing bees, and my custom is to stack the honey in a pile, and, if we do not sell together, give the owner the choice of what he wants for his half, say every other case. I furnish my own hive for my increase and he has my artificial swarm, and in one of mine doesn't build up, I lose it; if one of his does not, he loses it.

Mr. Collins—I have offered the first 20 books from each colony, just such as comes.

Mr. Pattee—I have had half of the honey and half of the increase, the owners furnishing their own hives. We divide the honey.

Mr. Dodds—If I think Mr. Collins' is the most desirable plan, there is another plan which I believe will do everything and own everything. There is then no choice for the owner to say that increase has been made with discrimination. The apiarist does the work and gets half the honey.

He simply puts his weight against the capital.

Mr. Pattee—I agree that we must give $11 off of 17 colonies, spring count. It took 2500 pounds of honey.

F. Rauchfuss—Now, let us hear a few bad reports.

Mr. Honnent—I started with 110 colonies, spring count, and I lost 35 colonies, which is $3500. I drove the bees to my apiary late, and I was not able to control the bees or the drones.

Mr. Brock—In my early experience I bought 40 colonies of a man who was to run them on shares. They increased to 66. Next spring I had three left and was $500 out.

Mr. Honnent—I endorse that plan of the owner furnishing everything. Then there is no clashing about swarms. The hives offset the swarms and fixtures. It is very equitable.

F. Rauchfuss—The most satisfactory way is for both parties to rent on a cash basis. Say there are 100 colonies. I pay $1 a year apiece, cash rental, and have an impartial person examine them on the first of October, to see that I return bees, supers, hives and fixtures in exactly the same shape that I left them. The lessee ought to be expected to furnish a bond or security. Of course, common law will protect the owner if damage is done. By this plan all increase goes to the lessee.

Mr. Harris—I in 1898 I put into winter quarters 85 colonies. The next spring I had 35 colonies, and got 800 pounds of surplus honey.

Mr. Collins—By my plan, if there is not much honey, you are out and there are no bees to divide. I would not follow Rauchfuss' plan for one year alone, if there is a little brood in the neighborhood, for it might appear in the apiary the next year, and I be held liable for introducing it.

F. Rauchfuss—Circumstances alter cases.

Mr. Honnent—In my locality I catch at least as many swarms from outside as come from my bees, and there would be a chance for a clash there.

Mr. Collins—I would have that covered by the agreement.

FAULTS THAT JUSTIFY REQUEENING.

Mr. Martin—A colony with a drone-laying queen should be requeened, providing it is populous. Otherwise, it should be united with another. If a queen is lost during the flow, the colony is populous, the colony should be requeened. I often requeen a colony soon after it has swarmed if I find one that has swarmed without my knowing it and cut out the cells at the same time. When I find a colony with an unproductive queen, I sometimes kill her. I also requeen colonies that show inferior traits. When a colony is far or on honey, or in some way are not good workers.

Mr. Collins—Do you not replace the old queens on account of age?

Mr. Martin—Not if they are prolific. Sometimes it is not the fault of the queen if the colony is weak. It is hard to lay down a rule. Then sometimes a colony with a laying worker does not wish to accept a queen. In such a case, I advise doubling to bring up with the natural population. This year I had two colonies whose honey was capped quite differently from that of the others. The combs were of a "washboardy" shape, and did not fill the section. In one hive I had three workers of that honey all capped, but it was all of second grade. Such colonies I would not requeen.

Mr. Kruger—Last May I found a colony with a drone-laying queen. It swarmed in June, and I gave one of the cells to the swarm and left two with the old colony. The swarm didn't, but a queen hatched in the old colony that never laid.

Mr. Sylvester—Queens are sometimes imperfect.

Mr. Harris—When I find laying workers, I move the hive some distance and put in two or three queens. Then I shake off the bees in front of the hive and introduce a queen, which is accepted.

Mr. Collins—I had a colony of laying workers that refused to accept any queen and on one of mine one of mine doesn't build up, I lose it; if one of his does not, he loses it.

Mr. Dudley—I used to move such a colony about 100 feet.
away and then shake off the bees. I think a better way is to put the hive on top of another colony which is not strong enough for the super. In a few days the bees will kill off the laying workers. You can then return the hive to its stand and introduce a queen.

II. Rauchfuss.—That plan is a good one, but one thing was omitted. A sheet of paper with a hole in it should be placed behind the two hives to stop them from fighting. Then the two hives might be left together. Some will say that makes one less colony. But if you want increase, you can raise up some brood into it from below, move it, and introduce a queen.

Mr. Dudley.—I forgot to say that I use the paper in uniting colonies to have two queen cells put out as soon as laying workers are found, that is a lost colony.

Mr. Lytle.—It is wise to supersede every queen that will not give as much profit as the average. It is not wise to supersede any queen that has given satisfactory service. I introduced with tobacco smoke. The way to do is to smoke thoroughly until every bee in the hive has been reached, then open the hive and let them run in. The theory is that the inside bees are stupefied, inquired the old queen, while the new queen is vigorous, and hence overcome her rival when they meet. In one instance I found the old queen lying outside of the entrance a few minutes after the new one was introduced.

Mr. Rauchfuss.—Is there not danger of robbing when this is done outside of the flow?

Mr. Lytle.—There is, and in three cases in which I did so after the flow, I reduced the entrance to a one-bee space.

Mr. Harris.—I tried introducing six queens with tobacco smoke, but all the bees were killed, and gave to the bees vigorous, and let the queens run in. Two or three days afterwards they were not there.

Mr. Kruger.—I use a cloth dipped in peppermint water, and laid over the frames. I have never lost one queen.

Mr. Rhodes.—Has any one tried smoking with cloths soaked in saltpeter water, and dried?

Mr. Rauchfuss.—Yes, that practice is common in Germany, and has long been known. It stupefies the bees so they drop off the cloths. There is another use of those salt-peter rags that I will call attention to, though it is not connected with the subject. They are just the right size to light a smoker with, since they do not go out after being once lighted. A small piece is sufficient to start a fire.

VALUE OF FREQUENT COMMUNICATION BETWEEN BEE-KEEPERS.

Mr. Foster.—I find that I secure my best points in beekeeping by button-holing my bee-keeping acquaintances. It also secures my own good name, especiallepecially when new flow brood is about. In this way I discovered and got rid of a bad case that otherwise would have been a menace to my bees. Free communication with reference to flow brood has such a value that it almost pays one to carry it on as missionary work.

Mr. Martin.—I moved 100 or more colonies into a new locality, where I had no time to look around. I noticed they were gathering honey very early, investigated, and found a neighbor’s colony being robbed that had foul brood. In another case I found a hive set out in which bees had died from foul brood, and bees working on it, though mine had not yet found it. I have had several such experiences, and have, therefore, made it a point to have frequent communication with my neighbors, whether it be welcome or not.

Mr. Collins.—I found a foul-broody colony once in a schoolhouse, where the bees had been for five years.

Mr. Honett.—I then gave two instances, mentioning the name of foul brood being moved into his neighborhood in former years, and added.

Mr. Honett.—This convention also proves the value of free communication, for many of us have ideas that we are not able to express until they are brought out by discussion.

Mr. Foster.—A friend of mine, who is slow to accept new ideas, came to me one day and said he had lost 40 or 50 swarms by absconding. On investigating I found that he had hired his swarms in hives with little ventilation, and set most of them in the hot sun without shade-boards. Those set in the shade above the city, in the green instruction, which communicated was probably of value to him in the future. Annual Report of the Colorado Board of Horticulture, 1899.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last.

The Afterthought.

The "Old Reliable" seen through New and Unreliable Glasses.

By E. E. HASTY, Sta. B Rural, Toledo, O.

THE GOLDEN BEES.

It’s a very singular state of things, to say the very least, which Mr. Doolittle narrates on page 501.

A leading breeder of golden bees, he has found on several occasions that they take hold of dirty refuse and break it up as well as soft water. The two are quite different fluids, chemically. Possible that brine may be the better of the two, but the probability looks strongly the other way. Perhaps the salt must be added after the soft water has done its work. Bolling brine

EXTRACTING IN HOT WEATHER.

When it gets to 110 degrees in the shade you must not extract unless combs are wired in for keeps. Arizona contributes this slice of wisdom; and we can believe it very easily. Most of us would prefer the hammock to the extractor at those figures. Page 505.

RELATION BETWEEN SWARMING AND HONEY-FLOW.

I take considerable interest in the experience of Wm. W. Case, page 507, that a heavy run of honey coming on suddenly stops swarming, without the swarming being violent, and stopped very suddenly; but my mind did not connect this with any change in the honey-flow. Perhaps if I had watched the honey-flow more minutely some relation between flow and swarming would have appeared.

A NEW BEE-SOCIETY SUGGESTED.

Mr. Bechly, we shall need a society for preventing cruelty to bees if you do not extend to the same extent of swarms that have been.

Mr. HASTY.—The "Light Brigade" were hardly more worthy of fame than those bees that hung out during the cooler portions of the torrid days, and marched "into the gates of hell," when it got its hottest, to save their brood by watering and fanning—i.e., they did it. Page 508.

HIVING SWARMS WITH WEAK COLONIES.

As to hiving in swarms with weak colonies, I am still undecided as to whether it is worth while or not. Tends towards having all colonies strong," but don’t believe I practice it very much if I was sure of an abundant supply of hives ahead. Saving the queen of the weak colony, and giving her an immediately too-large normal swarm, is a kink which will bear thinking of. If she was to blame for her colony’s being weak, the other colony would better rear their own. In the much more common cases of bad food or bad keeper, it looks good practice—provided experience does not find it originating a second series of swarms. Page 507.

SPLETS VS. WIRE FOR FOUNDATION.

Splits standing in saw-kerbs at top and bottom, oh? Little by little a method gets the additional touches it needs to make it complete. Who knows what wire for staying foundation will eventually take a back seat and let splices see the play from the front row? Page 508.

PAPER SACKS FOR KEEPING HONEY.

I doubt if Mr. Davenport’s tombstones will say anything about his adopting the paper sack to the carriage of honey. The little packages will come to grief at the hands of the hired girl, and not beget the true love of the freight handler, methinks. If everybody read and obeyed directions it might be different. Page 517.

RENDERING WAX WITH BRIMY WATER.

For rendering wax, the inside fitting sieve of Adrian Getaz, to boil the wax into, looks a good thing. And to increase five fold the rising force of wax is quite a brilliant thought. Good boy but! Even a good boy sometimes has a brick back to his head. You should have the hands of the freight handler, methinks. Will the salt be added after the soft water has done its work. Bolling brine
Honey from Mulberry Fruit (?).

If Dr. Peirce has honey that was stored from white mulberry fruit, and it is good, he has done experimental apiculture properly good. But I hope he will pardon the grain of salt slowly melting on our tongues. If we knew he fed a colony at least five pounds in 48 hours—if we knew said colony didn’t get over a pound of nectar meantime—if we knew “the man on the fenceline” found a marked difference in flavor between the honey and the honey in the next hive—I am not asking him these questions. I am only ruminating them. On the whole, I think I have more faith in that currant mulberry jam. Page 524.

Questions and Answers.

Felt Roofing for Doubled-Walled Hives.

Has any one had experience with felt roofing? If so, what satisfaction does it give? I want to build some double-walled hives and try it. Also state whether two or three ply is required.

Michigan.

Answer: I know nothing about the matter from experience, but should expect good results. Can any one tell us anything about it from actual practice?

Keeping Bees on Shares.

I have 10 colonies of bees—11 in dovetail hives. I have winter-cases for 25 colonies, foundation-fasterner, bee escapes, and some other appliances. The colonies are all strong and healthy, as were examined by J. M. Kandeler, at Rockford, Ill. When he visited my place, he having the whole care and all the sales to make.

What share should each one have? Michigan.

Answer: Your conundrum is a tough one. So much depends upon the knowledge and skill of the man who has the bees in charge that about the only thing to do is shut one’s eyes and make a guess. Taking into account what you say of your neighbor in a private note, I should guess that you should be satisfied if he turns over to you one-third the amount of his sales. But mind you, I don’t guarantee my guess; neither do I agree to replace it with a new one in this case should not give satisfaction.

Perhaps No Disease at All.

I send a small piece of brood-comb for your examination. Can you tell me what it is? It does not seem to have the symptoms of foul brood, nor pickled brood, as I think they both are, as I have neither a larve, and you see the bees are perfectly and nearly ready to hatch. I might think it a case of chilled brood, but I had a colony similarly afflicted July 16, and I would not think brood could be chilled at that time. I have two colonies mixed with it on shares to a neighbor, he having the whole care and all the sales to make.

What share should each one have? Michigan.

and hold down the one who may seem to oppose—all tend to break selfishness.

The poor man—the average laboring man—early learns self-denial. He is not pampered, and becomes thoughtful and kindly towards others. He is tried by very circumstance in the way of selfishness. The rich person in the cradle has learned the art of selfishness by unfailing life that the poor man has. Condition of life is what swerves him to the wrong and unfeeling. Hence the words of Shakespeare: "I’th’ rather red a dog and bay the moon such a man." And Christ’s "...and the kingdom of heaven is like a man which gave his servants money, and sent them into the world and said to them, ‘...’.

Are riches, then, worthy the coveting? Are we wise to bend the necks of the rich by envy? The poor man is in best house of character development. With a nation of such are we safe. We may all hope and pray that our people may be all in comfort. We may well work and legislate that few gain extravagant wealth. The laborer gains his ends by wise budget. It is the world’s wealth and blessing. He also has the dignity of position that comes from independent maintenance. The very rich, with few exceptions, either have had their wealth poured into their laps, or else have gained it through questionable methods, and with out giving value received. In either case they are not to be envied, and have not the best citizenship.

That the poor man labors under the burden of a fearful handicap, is shown in the report from one of the iron-mine towns, where the taxes of the mill property were fixed at less than the value. It was the practice of the town to grant this and to any other, and also, and willing—to their shame be it said—to secure this unfair and wickedly inexorable reduction. Can these unfair advantages reduce the war, as thick as pebbles on the beach, ever be stopped? They can and will be. I hope soon. The power to do this will only come through complete cooperation; when the laborers, through the wise management of their trust, ablest, best men, will have their voice and influence with men and capital who employ them. The laborers are so many, and so scattered, and often so ignorant, and so blind to their own best interests, that it will take long to bring this blessed consummation. Complete union with education to make it safe, and its behests right and wise, is what the country and the laborers most need. I believe it was to promote such union that this strike was ordered. If it helps even a little to bring it, it will be worth all its costs. If it was ill advised, and does not hasten the day of fullest cooperation, then it is greatly to be regretted.

I long to have the "other half" in such complete union and accord that they will act as one man. Then they can hold up their heads and can dictate equally with the employers. Then, and not till then, will the laborers cease to have a grievance. Any discontent that hastens education and fosters union is baleful, and should receive our sympathy. A strike that hastens on complete union—at least complete enough that the laborer may have which none in the settlement of all disputed questions—is to be desired, if there is no other way, even though it beases a little of business disasters and commercial interference that may touch our liberties as easily, and far and wide.

It is to be regretted that arbitration rather than strikes can not be used to hasten effective union. The men who inaugurated the strike expected that their action would hasten and strengthen more complete co-operation. But they were not in a position, then they acted wisely, even though the great public is wholly against them. If they judged wrongly, and so delay the day of fullest union and oneness, then their action is greatly to be regretted. The injuries to others, and general suffering, are most unfortunate, but our greatest reforms often mount upward on the stairway of pain and suffering.

Let us all in our homes strive to beget in our children right views and feelings regarding all these great issues.

THE ARMY CANTEEN—PROHIBITION.

I am glad our old friend, A. I. Root, sounds forth such wholesome views regarding the canteen. While I have always voted with the Republican party, and am not ready yet to sever my connection, I have great sympathy with prohibition. If I thought voting prohibition would hasten it, I should hesitate a moment. The production of liquor is the greatest issue before our people. The saloon men always light the canteen in the army, prohibitory laws, local option, every effort to stay the liquor-traffice. If the canteen were favorable to temperance, why would the saloon interests be solid against it? I hope the law against the canteen will hold its grip in our statute books.

[We would like to suggest to Prof. Cook that it is not a question whether voting prohibition will bring prohibition; it is rather how a conscientious Christian man can continue to vote with saloon-keepers, brewers, etc., and still retain a clear Christian conscience, and also see any hope of staying the saloon evil.

A bigger question just now than the saloon question is this: Are the Christian voters of this country going to do their duty—live right up to their church resolutions on the great subject of prohibition, or, are they going to continue to stand before the world as inconsistent people, talking one thing and doing another?

Personally, we are consistently and eternally against the saloon, and intend to continue to use the heaviest possible weapon for its overthrow, namely our vote. We don't have to win in this fight, but we do have to do the right, and our consistent duty.—Enthus.]

Much Interested in Her Bees.

A queen I sent for came safely to hand last Friday, but was not introduced to the hive in the afternoon. To-day I looked into the hive and found her lying nicely. She is fine looking and healthy, and much pleased with her; I feed them a little syrup every night. I think the queen had been queenless some time. I had been away from home a couple of weeks and found them queenless upon my return, I hope to do well with her another year. This seems to have been the case and I become more and more interested in them.

Calahan, General Agent, 111 Adams St., Chicago.

An Experience in Transferring.

EDITOR YORK:—I recently wrote to know if our club could supply several members of the American Bee Journal, and you kindly sent me a few. Since becoming a subscriber, I find them useful, and every bee-keeper should have one of the Emerson binders to keep from misplacing them as I did.

For instance, to show their usefulness, I wanted to unite, and at the same time transfer two weak colonies from boxes or supers to movable-frame hives, and I readily found advice by looking over some of the back numbers, and went to work. It being my first job, I began about as timidly as a young surgeon would when amputating his first limb from a human being. However, I made a complete success, which I will tell for the benefit of beginners like myself.

I first moved one of the box-hives close beside the other to be united, several days beforehand, for them to get acquainted with all the smells and sounds.

When the proper time arrived I went to work as follows:

First, I prepared a table by placing a wide board over a flour-barrel and folding a crocus sack several times over the table, and on top of it spread a paper, each corner of which I provided myself with all the necessary tools, etc.—a honey-knife, narrow chisel, and the clamps—made by tying two Narrow strips of tin-wood together at one end, and leaving the other two open to be tied after placing them around the comb.

Next, I moved both hives back about two feet and placed a movable-frame hive about half way between the location of the two hives.

I next opened one of the hives and took out a comb and fastened it in a frame of the new hive, having wired the box-frames first, and then cut the combs to fit into the frames the best I could; and then the wire on the underside holding the combs till I could fasten the clamps.

In wiring my frames I placed the wire to one side of the frame, but kept it in the center. This gives room for the comb to rest well in the frame, which I find much better than to have it along both edges.

I took pains to put the brood in the center of the hive. I first used up all the comb of one box-hive, and then brushed all the same preparatory work on the best and fullest combs. Remember, I brushed the bees off of the combs back into the old hive, making a complete transfer, and then getting down the second box-hive and brushing the bees of the combs into the new hive, and by the time I used the last comb of the second hive I had nearly all the bees in the egg-laying stage.

Mulberry Growing.

Will Dr. Peirce give answers to the following questions in the American Bee Journal?
1. How large do mulberry trees become as to height and spread?
2. How long from maluable or expressable sapling to fruiting?
3. Is the white variety better than the black? Is there a difference in hardness?
4. Is Russian mulberries right the rightness?
5. Can I find other names of white varieties, but no Russian?
6. Is it kind better adapted to dry places than others?
7. Is it liable to attacks of any pests?
8. Do they grow well on the borders?
9. The American Encyclopedia says it is closely related to the fig. Has it similarly enclosed numerous seeds? Is "fruit" being the literal receptacle? Monterey Co., Calif.

A. NORTON.

Dr. Peirce has kindly replied to Mr. Norton's questions as follows:
1. Black mulberry trees grow to 20 inches in diameter, while the white variety does not attain so large dimensions, to my knowledge. Both spread broadly.
2. They bear fruit in about five years.
3. The white variety is best at honey-producing, being much sweeter than the black. I believe both varieties to be equally hardy.
4. "Russian" is the usually accepted name for the white. It may only be derived from its capacity to withstand extreme cold without material injury.
5. I believe the various kinds are equally hardy in dry localities.
6. I know of no insect that seriously injests the mulberry. It is clean and apparently free from diseases.
7. I do not know that bees work on its minute blossoms. I would not depend upon its possibilities.
8. Yes, the mulberry is not remotely allied to the fig, in general growth, resemblance of leaves, and anecologic features. The flavor of the white mulberry is more like that of fig than the black, though this may not be apparent to all tastes.

Finally, the cheapest way (and it seems to me, the best) is to insert cuttings in places where they will root and remain. This should be done in July or early in August.

Du. Peirce.

Bees and Mathematics.

The construction of geometrical spaces is not only the mathematical operation of creating by hand and mind, a work represented by M. Nettet, who read a very interesting paper on this subject before the Paris Academy of Sciences. The Referee Scientific reports that he brought out the following facts:
1. Not only is the construction of the cells east of mathematical nature, but many operations of the insects also; for instance, the collection of the maximum amount of honey in the minimum time, and the division of the workers among the plants proportionally to the number of plants of the same species. In the hives, the number of bees engaged in ventilation is almost directly proportional to the daily increase of weight of honey, etc. Facts of this order relate to interdependence of plants, while there are others to do with cell-building and two-dimensional geometry.
2. Nettie is of the opinion, however, that this is a show of apparent intelligence on the part of the bees, that "all their movements, without exception, are of the nature of reflexes; that is, performed without conscious action, just as we close our eyes instantly when a strong light comes near them." -Translation made for the Literary Digest.

"Reviewers" from the Beekeepers' Review.

Bee-Escapes should be placed at the corner of the board instead of the center. Mr. John, of St. Louis, this week have hives around the edge of the board in their efforts to escape.

Ontario, Canada, has a good crop of honey this year. I think that 75 pounds of extracted honey per colony would be a safe estimate; although many report a yield of 100 and 125 pounds, and H. G. Hubbard's colony averaged 150 pounds from three yards.

WIRE-CLOTH supports for the combs are used by F. A. Vermillion, in Ontario, in the following manner: A wire cloth is tacked upon frames laid over the metal bottom of the extractor, and then refuse combs laid upon this cloth. The wire cloth catches and holds most of the cocciens, etc., and prevents them from running down in the bowl.

CLIFF HAZL. likes how the bees occupy the same stand year after year; as it is much easier to remember the characteristics of a nest that always stands in the same place. This is one reason why he is particular, when taking the bees off the cellar, to place each colony in it permanently.

Foul Brood can be treated in the season, after brood-rearing has ceased, by shaking the bees off upon sealed combs of honey. But little infected honey they carry with them will all be consumed in a short time—long before brood-rearing will again be
Langstroth on... The Honey-Bee Revisited by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son.

Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for $1.25, or club it with the American Bee Journal for one year—both for $1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with $3.00.

This is a splendid chance to get a grand handbook for a very little money or work.

A Foster Stylographic PEN...

This pen consists of a hard rubber holder, tapering to a round point, and writes as smoothly as a lead-pencil. The point is twisted, and when the pen, which are made of platinum, alloyed with iridium—substances of great value—comes in contact with the paper, it is affected by the action of any kind of ink. The pen is half a sufficient ink to write 10,000 words, and do not leak or blot. It makes a line of uniform width at all times they are unequalled for ruling purposes. Pens are furnished in neat paper boxes. Each pen is accompanied with full directions, filler, and cleaner.

Best Maniplating Pen on the Market.

THOS. C. STANLEY & SON, 31 AIt.

FAIRFIELD, ILL.

Please mention Bee Journal when writing.

CHICAGO, Aug. 23.—White comb brings 15c per pound for the choice grades, with other honeys not over 10c per pound. Next highest color, light amber, 12%–15c; dark, 10%–11c. Extracted, fair demand at 15c per pound, dark amber; dark grades, 5c. Bee-steady at 35c for choice yellow.

R. A. BURNETT & Co.

CINCINNATI, Aug. 16.—The honey market is very fast at present. Extracted sells only to manufacturers from 50c; better grades at white, 75c; honey, 65c; white comb honey from 85c–90c. Fancy white comb honey sells from 125c–130c.

C. E. L. W. WEBER.

BOSTON, Aug. 14.—Our market today is about 106c–107c for fancy; A No. 1, 154c–155c; No. 1, 148c–150c. Extracted, full color, 75c–80c. Several lots of new Vermont honey in carlots have thus far been received, meeting a ready sale at 12c, 15c, and 17c a pound, of course in a small way. The trade generally seems disposed to hold off, looking for larger receipts and lower prices. This is somewhat due, of course, to the fact that the demand is still light owing to the warm weather, and cooler weather is expected to give better demand and naturally make a better feeling.

ALBANY, N. Y., Aug. 20.—We quote: Fancy white comb, 116c; No. 1, 115c; No. 2, 130c; mixed, 120c. Extracted, light, 75c–77c; mixed, 55c–60c.

OMAHA, Aug. 8.—New comb honey is arrived in express by small quantities from Iowa and Colorado, and selling at 50c per case in a retail way. California extracted honey has been arriving here in carlots at 45c–49c per pound, f.o.b. California shipping-pole, but we have not heard of any sales having been made thus far. The production of extracted honey in California is so large this year in Colorado, Utah and California.

PEYCE BRO.,

NEW YORK, Septh. 9.—Comb honey is now beginning to arrive in large quantities, and with a rule, quality is fine. The demand is good, and we quote as follows: Fancy white, 140c; No. 1, 130c; No. 2, 125c; and amber, 110c. No buckwheat is being sold at the present time, as we are taking same within a week or so. Extracted is selling very slowly, with plenty of supply, at 54c–56c, acetone value to quality, from 70c to 90c, and white, at from 86c–88c per pound. Beeswax dull at 27c.

C. H. B. & S. DEEBOLE.

DES MOINES, Aug. 7.—There is very little doing here, new crop of honey is not yet in. Some small lots of near-by produced comb honey are on the market, selling for fancy, 100c–115c, and lower grades, 125c–old neglected. Advise moderate shipments only of new as yet. C. H. HENT & SON.

BUFFALO, Aug. 10.—Quite a good demand for fancy honey, 100c–115c, and lower grades, 125c–old neglected. Advise moderate shipments only of new as yet. BATTERSON & Co.

SAN FRANCISCO, Aug. 14.—White comb, 110–115c; amber, 80c–90c; dark, 66c–70c; extracted, white, 55c–60c; light amber, 45c–52c; amber, 44c–50c.

Market continues quiet, with apiculturists, as a rule, granting a range of prices of 2c, 4c and 6c, named by wholesale operators. Quotations represent as nearly as possible the values ruling at the date for round lots, small carlots could not probably be effected at full figures, while on the other hand, higher prices than quoted are being realized in the filling of some small orders.

BETHLEHEM, City, Aug. 6.—Some very fine Missouri honey is now on the market, selling at 105c–110c for fancy white comb. Colorado and Utah honey shipped here in carlots in cartons for first batch of August shipments, 75c–85c per pound, f.o.b. shipping point. For No. 2, f.o.b. shipping-point. The market for extracted honey is as yet not well filled, asking prices ranging from 45c–64c, f.o.b. shipping-point. Buyers, however, seem to be in no hurry to make contracts.

—THE—

Bee-keeper's Guide

Or, Manual of the Apiary.

By PROF. A. J. COOK.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPERS' GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting new subscribers for the American Bee Journal.

Given for TWO NEW Subscribers.

The following offer is made to present subscribers only, and no premium is also given to the new subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with $2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for $2.25, or we club it with the Bee Journal for a year—both for only $1.75. But surely anybody can get only TWO new subscribers to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will you have one?

—RED CLOVER QUEENS—

BLACK ROCK, N. Y., Sept. 3, 1901.

FRIEND ERNEST:—I will try and tell you what you want to know about that queen. I got her of you in 1899 as a premium with GLEANINGS. I never saw a small colony of bees build up as that one did. In the spring of 1900 they came out in fine shape, wintered perfect. I raised them up in May and gave them 8 frames more so the queen would not want for room. I never saw such a colony of bees as they were in June, and they were actually storing honey where other bees in my yard were starving. No! they were not robbing. I never saw such bee colonies of mine trying to rob. THEY CERTAINLY WORK ON RED CLOVER. This is no guesswork, as I have seen them. As you know, the past two seasons have been very poor, and what honey any bees did get in 1900 candied soon after cold weather set in. I packed this colony in a sheet hive and left them out, thinking that such a strong colony would winter perfect. The snow came on the middle of November, and those poor bees never a fly until the last of March or the first of April. When warm weather at last came I thought they were dead, as they did not seem to be flying much, so I did not pay any attention to them until in June. I noticed they were working a little, so I opened up the hive and found them in the upper story. I took the lower story out and left them in the one body. The queen was laying nicely, and I thought they would make a good colony to winter. Along the last of July I noticed that they needed more room. I gave them a super, 31 boxes, and in a few days they had filled. They have made 72 boxes of nice honey as you ever saw, and are drawing out some starters now, Sept. 2.

Very truly yours,

GEORGE R. HOFF.

The "Barler Ideal" OIL-HEATER....

Saves Its Cost Every Year!

NO ODOR! NO SMOKE! NO ASHES!

Costs only a cent an hour to run it.

The editor of the American Bee Journal is using the "Barler Ideal" Oil Heater, and it is all right in every way. We liked it so well that we wanted our readers to have it too, so we have recently arranged with its manufacturers to fill our orders. The picture shown herewith is the one we recommend for general use. It is a perfect gem of a stove for heating dining-rooms, etc. It hinges back in a substantial way, and is thoroly well made throughout. The urn removes for heating water. The brass fou on or well has a bell, and holds nearly one gallon of kerosene oil. It is just as safe as an ordinary lamp. You wouldn't be without it for twice its cost, after once having one of these stoves. Most oil-stoves emit an offensive odor, but this one doesn't. Its height is 2½ feet, and weighs 20 pounds, or 20 pounds crated ready for shipment, either by freight or express.

Price, f.o.b. Chicago, $6.00; or, combined with a year's subscription to the American Bee Journal—both for only $6.50. P.U.B.L.I.S.H.E.D W. YORK & CO., Chicago, Ill.

No. 1 "Barler Ideal" OIL-HEATER.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

HOWARD M. MELBEE, HONEYVILLE, O.

[This cut is the full size of the knife.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drones, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The husters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife?—In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your Pocket-Knife will serve as an identifer, and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a fair idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be believed. Hive rooms, bee-rooms, and baths-rooms.

How to Get this Valuable Knife.—We send it postpaid for $1.25, or as a Premium to the one sending us TWO NEW SUBSCRIBERS to the Bee Journal (with $1.00). We will club the Novelty Knife and the Bee Journal for one year, both for $1.50.

GEORGE W. YORK & CO.,
St., Chicago, Ill.

For 40c please allow about two weeks for your knife order to be filled.
Bees and Pear-Blight.—The fruit and bee men of California seem to be sensible enough to get along without quarreling and bickering. One of the bremen show an excellent spirit. They have agreed to move their bees away from the pear orchards during the blooming period, so as to help solve the question whether the bees are the chief criminals. The views of some of the scientific men are given in Gleanings in Bee-Culture. Prof. Waite seems inclined to pass judgment against the bees, but at the same time considers them a necessary evil, for he says he has found as the result of an extensive series of experiments "that bees are indispensable to the pollination and setting of most of our pomaceous fruits." Prof. Cook says: "I have little doubt that bees do aid in scattering the virus; but I am far from convinced that their removal will abate the trouble, or is wise and necessary."

Prof. Gillette thinks it will be a considerable time before we can draw any positive conclusions. He thinks that if the bees were the chief operators the late varieties of pears should suffer more from blight than the early ones, and he has not observed this to be the case.

"Honey Without Bees."—Dr. R. H. Strickland, of Perry Co., Tenn., sends us the following, which appeared in an advertisement taken "from a scientific (?) quasi-medical journal:"

**Honey Without Bees.**

This is an age of marvelous discoveries and inventions. Every day brings forth something new, and every year is marked by some astounding discovery which completely upset all preconceived notions in some department of knowledge or industry. Marvelous discoveries have been made in electricity and the uses of steam and the utilization of the various forces of nature, but a discovery which is really more far-reaching in its results, and perhaps capable of immediately benefiting a larger number of persons, is a process worked out by an eminent physician by years of laboratory research, whereby it is possible to make honey directly from wheat and other cereals without the aid of chemicals of any sort, and by a process essentially identical with that by which honey is manufactured by plants ready to be collected and stored by the cunning little feet of the honey-bee.

Malt honey, or molasses, looks like honey, tastes like honey, in chemical composition is essentially the same as honey, and as a food is superior to honey, since it is free from germs, poisons, fragments of flowers, dust, and other foreign matters, and may be eaten without injurious effects, even by most delicate individuals, whereas many persons can not eat honey, even in small quantities, without experiencing ill effects. Malt honey is genuine honey; not an imitation or a substitute, but the real thing, trader from the original source—the plant—but without the assistance of bees, and by a process which renders it absolutely pure and wholesome. It is the only sweet which can be eaten in liberal amounts without injurious effects. [Italics are ours.—Ed.]

We feel a just pride in the perfection of this very remarkable and useful product, after spending some years and thousands of dollars in research for the purpose.

Dr. Strickland says in his letter accompanying the foregoing, "It may not be worth noticing."

Well, it certainly wouldn't be "worth noticing" were it not for the wonderful in which the thing is described and advertised.

If its discoverer doesn't know any more about food products than he does about the way bees gather and store honey, he is truly a fine specimen of ignoramus. Think of bees collecting and storing the nectar of flow-ers. Then think of the honey bee! If that were true, they ought to store about six times as much as they do, as they have six times as much feet as tongue. If this learned (?) food inventor were right, bee-keepers would be breeding for more and longer feet than for longer tongue-reach in their bees.

Well, we secured a sample of the wonderful (?) "molasses" that is said "looks like honey, tastes like honey, and in chemical composition is essentially the same as honey," etc. If honey were like it, we would care for no more honey. It has a taste (to us) almost like sorghum molasses, is thick and cloudy, resembling in appearance a poor quality of glue or mucilage. If we were to put up for the Chicago grocery trade stuff like it, and call it honey, we would expect to kill our trade on the first round among our customers. And yet, the great inventor of "molasses" says it is "genuine honey" and "the real thing." True, he says bees had nothing to do with its manufacture—and we believe him.

Bees wouldn't degrade themselves by turning out a product like "molasses"—not from the blossoms of white clover, bassew, sweet clover, etc. The idea of man claiming he can make honey equal, or superior, to that produced by bees! (Of course we mean the best grade of extracted honey, not honey-dew.)

From the glowing advertisement of "molasses," one might be led to think it is a sort of con¬dum honey. It isn't. It is simply an imitation of extracted honey, and we consider it a fraud one at that.

We do not say that molasses has no valuable food qualities—we know nothing about that part of it. What we object to, is the claim that the stuff is the "same as honey" (bee-honey), "the real thing," etc. Also, the attempt to prejudice the public against genuine bee-honey, by claiming that it contains injurious "germs, poisons, fragments of flowers, dust, and other foreign matters," deserves to be severely condemned. No honorable man or firm would do that.

It's a pretty safe thing to shun people who claim they have "genuine honey" that was produced "without bees!"

Sugar for Bee-Feed.—For years a difference of opinion has prevailed as to the best kind of sugar to use in feeding bees. Those who are supposed to know tell us that granulated sugar made from beets is identical with that made from cane-sugar. But things that are identical from a chemical standpoint are not always the same, as witness the familiar instance of diamond and charcoal; and across the ocean it has been earnestly insisted that sugar from beets was unfit for bees, and that cane-sugar alone should be used. If it were easy to be sure of getting cane-sugar, the safe thing would be to use that alone, but one can not be sure of what granulated sugar is made, and the amount of bee-sugar is all the time on the increase. Since we are in a manner forced to use what is very likely to be bad-sugar, we may take some comfort from the experience of Editor Root, remembering that the proof of the pudding is the eating. He says in Gleanings in Bee-Culture:

Personally I do not have any uneasy feeling about the sugar question. It is not proper for us to boast; but for the last 10 or 12 years we have used beets-sugar for feeding our bees; and if any one can show a higher wintering average than we—one who has used cane-sugar—we should like to have him hold up his hand. Our wintering losses very often do not exceed 2 percent, and the very highest is 15 percent, 1 believe. This covers a period of about 20 years. I suppose a fair average would be between 3 and 4 percent. If Mr. Morrison is correct, the beets-sugar is better than cane. But my honest impression is that, with either sugar, we shall get good results. The trouble from sugar-fed colonies is more because the syrups is fed too late or too thick, and the bees do not have opportunity to ripen it. If it is fed during warm weather, when they can fly, half and half, other things being what they ought to be, I would not give two cents to have the colonies insulated.

A New Honey-Plant is announced every now and then, and at different times there has been a sounding of trumpets over some new plant that was to be kept by the bee and give wondrous yields, as for example the Simpson honey-plant, figwort, and Chapman honey-plant. Acres of ground were planted with these, and at the instigation of bee-men the Government made an appropria-
tion to distribute the seed of one of them, but at the present day little is heard of them, and it is not likely that any one considers it advisable to make a planting of either of them.

It seems pretty well settled that to make it profitable to occupy tillable land with any honey-plant, that plant must have a value aside from its honey-yielding properties. Hopeless, therefore, is the attempt to regard a plant for honey alone, there is always a possibility of the discovery of some plant of value for other purposes which has the additional value of being a honey-yielder. Even the remote possibility of such a thing makes it worth while to experiment with a large number in the hope that out of the many there may be found one that will be profitable.

In the National Stockman and Farmer, the winter or hairy vetch receives high praise as a plant for feeding and other purposes, but no mention is made of its honey-yielding qualities. In a late number of that excellent farm journal J. A. Macdonald speaks upon that point in this wise:

Some months ago I made mention of the winter hairy vetch article in the National Stockman and Farmer, but in mentioning many of its various points of value, as a pasture plant, manure producer, and value, etc., I did not observe that this vetch was a splendid honey-plant, and that clover deed better through a comparison with it, regard, for the reason that the time of bloom of clover is comparatively short beside hairy vetch, and that the red clover which the readers have noticed this new value of this vetch: if they have, they have taken very good care to keep the plant from blooming. You may have a correspondent, Mr. Lightly, and a bee-man, too, has spoken, in your columns, of the marvelous capabilities of hairy vetch, but I, at least, have failed to see any mention by him of the honey-yielding qualities of the plant which you mentioned now ask him to say if he ever noticed this point of value.

First, let me say that there is no more beautiful sight than to look upon a field of hairy vetch in full bloom, and this view presents itself for a very long time, and this is why such a remarkably fine honey-plant, superior to any other that we have seen for weeks. You see this vetch, when sown in spring, is very tardily in maturing seed, but continues to put forth and add to its quantity of bloom all through the warm weather while most of the vetches are exceedingly fond of. On a patch of this vetch sown May 10, I noticed, two weeks ago, about the first week in July, that it was not until three weeks later, or the last week in July, that it appeared in full bloom, and still at this date (August 31) it is in the midst of its brilliant bloom, though pods are maturing on the lower portion of the plants. For the last ten days the plants are literally covered with bees. A few days ago I tried to estimate the number of bees fleeting from bloom to bloom, and so far as I could read there were an average of ten bees to the square yard, that is, in the immediate vicinity of the patch, and I never have seen bees working so greedily. You say there are no more than four or five bees working to the square yard, but no matter what you have to go into this patch (which, by the way, we are cutting for partial sowing of cows and pigs), there are lots of bees and continually.

Hairy vetch is a wonderful plant indeed, so much so that you have seen of it, but it would be considered with at all. As a pasture for swine it is fine, and though I never cure any of it for feed, it is always good for this purpose, too. As a spring crop with me it is ahead of a winter crop, and produces the finest feed and best forage per acre, and lastly it comes its wonderful value as a honey-plant. I wish bee-men everywhere where it would give the bee their honey-yielding qualities; and I would greatly wish to hear from those having the hairy vetch growing to report its value in regard.

Now in the hands of others this plant may or may not be found of value. The probability is that in some localities it will deserve the kind words with which Macdonald speaks of it, but in others it will be of little value. But the possibilities in the case warrant a thorough trial on a small scale. Its long period of bloom, and its continuance in bloom after white clover is done are special points in its favor wherever it is found to be a success.

Has anyone of our readers had any experience with the plant? Has any one any further knowledge of it? If so, let us have all the light possible about it.

---

**Weekly Budget.**

President William McKinley—the most widely respected and honored president of the United States in our generation—was also a persistent demon in human form, while he was holding a reception at the Pan-American Exposition at Buffalo, Sept. 6. The terrible wound resulted in his death early Saturday morning, Sept. 14.

Of course, this is no news to the most of our readers, as the daily press has been crowded with typical and column at this awful event. It is almost too sad and terrible to write about. There should be no room for a single anarchist in this "land of the free and home of the brave." We strongly favor the suggestion that all the anarchists in this country be exiled to two high-walled islands of the sea, the men to be assigned to one island, and the women to the other. Give them sufficient to eat as long as they live. After that the "bread" would be at an end.

We have not the slightest sympathy for those who would shoot down any one placed in official position, and the sooner such tardy cowards are hanged and the better disposed of the better for all concerned.

---

**Getting Late for Queen-Orders.**—On account of the season getting late—cool weather, etc.—we wish to announce that we will be unable to accept any more queen-orders to be filled this season. We appreciate very much the queen-patronage that has been extended to us this year, and trust that it may continue next season. We also hope that all the queens received through this firm may prove entirely satisfactory, as we believe they will.

HON. J. M. HAMBURG, writing us from San Diego Co., Calif., Aug. 31, had this to say:

"Thank you, Mr. Hamburgh, for such expressions of kindly feeling and appreciation. Such go far toward resting the tired head and hand that often come so through the incessant efforts necessary to be put forth in order to send out the old American Bee Journal every week in the year. But, after all, it is a pleasant work. And one can keep on doing it, with an honest feeling that he is really doing something—spreading the gospel of knowledge, who want and need just such aid as this journal gives.

To all our increasing thousands of readers we pledge continued effort and devotion, health and strength permitting."

---

**Home and Apary of J. W. Adams.**—On page 615 will be found a picture of "Oak Grove Apary, belonging to J. W. Adams, former owner of Mountain Apary, Tex." He took his first lessons in bee-keeping from his grandfather when he was a mere boy, but never kept bees until after he was married. He moved to Texas in 1884, and seeing so many bees there the old desire to keep them was revivified, and so he bought some black ones in brick-hives; these he kept, but with sad results. Last winter he was struck by making a study of the bees, and reading all the books he could secure, he has made a success of the business. He is also a farmer and stock-raiser.

Mr. Adams secured about 100 pounds of comb honey per colony last season (1899), which he sold at $12.50 per pound. He gets 9 and 10 cents per pound for extracted honey, and has no trouble in selling all the honey he can produce, at these prices, and the middle of June he was behind 1000 pounds on his orders. He is the only practical bee-keeper in that locality, but through his efforts some have become interested in bees, and others have begun to save their stock, and adopt the standard hives. In the picture, the little girls to the left are Mr. Adams' daughters, the little one in the buggy is the baby, and the young man in the background is his eldest son, who has charge of his queen-business.

---

**Friend York.**—The reliable, old American Bee Journal, born companion to the wide-awakes in the olden time, and always welcome here in this far-away land of the Sunny Pacific Slope, I am afraid there are very few up here who fully appreciate the energy and grit of the Editor who so faithfully compiles and prepares a weekly intellectual feast for its patrons upon topics relating almost exclusively to the honey-bee. Long may the old, faithful American Bee Journal live and prosper under the guidance of our "auld lang syne" friend, George W. York, is our sincere wish.

It seems that fate has placed me at the extreme western limit of Uncle Sam's domain, where I am isolated from the haunts of my early life. Yet I can live with no regrets, and have many reasons to be thankful, chief among which is an added lease upon life. Myself and family have a much better health here than we did in the East. The daily visitations of the cold, invigorating salt-water air, is a panacea for almost every human ill, and hundreds and thousands at this season of the year lie away to the banks of the Pacific, and may be in a much better health here than we did in the East. The daily visitations of the cool, invigorating salt-water air, is a panacea for almost every human ill, and hundreds and thousands at this season of the year lie away to the banks of the Pacific, and may be in a much better health here than we did in the East. The daily visitations of the cool, invigorating salt-water air, is a panacea for almost every human ill, and hundreds and thousands at this season of the year lie away to the banks of the Pacific, and may be in a much better health here than we did in the East.

The Honey Market and Crop in California.

By Geo. W. Brodeick.

We bee-keepers of Southern California have been forced to confront conditions in the marketing of our product this year that we have never been obliged to face before, and I firmly believe that if the majority of our bee-keepers were patrons of our leading bee-suppliers, this state of affairs would exist.

Every season we are informed from outside sources (and sometimes within), that Southern California will have an enormous crop of honey, and it matters not whether the conditions are favorable or not (last year as an illustration), with the consequent result prices are established before the honey is ready for the market and the amount produced is unknown. This year has not been an exception in this respect to the past, but that which has lent additional interest and more than all else to depress the market, has been the production of wax for our own use.

The object, of course, is self-evident, for the circulation of the rumor of a large crop has a depressing influence upon the bee-keeper who is forced to sell, and when the middleman quotes a well-known bee-keeper as authority, lends a vitality, the statement; and as the former has no means at hand to know of the vast quantity of honey that has been shipped to the United States from Cuba, Hawaii, and Puerto Rico, (this information is bought by the buyer or go-between), knowing not whether it is true or false as to state of market, etc., he quietly submits and sells for the price offered.

We all know beyond question, that at the beginning of this season we had less than one-half of the bees to produce a crop with than four years ago, and yet the statement has gone forth that we produced as much, and more, than we did four years ago. I know beyond question that we have many honest buyers, and I know of bee-keepers who have been aiding these men in a legitimate way, but when men from our own ranks circulate statements with the express view of depressing the market, and thereby affording them a profit, I think it is time the California bee-keepers were warned against their practices, and it is this which prompts this article.

While I am not disposed to pose as authority in regard to this year’s crop, information from some of our leading bee-keepers, and other sources, indicates that we have produced about 150 car-loads of honey, all told. Over half of this has been marketed. Comb-honey has been produced in limited quantities, due to unfavorable conditions, and this has nearly all been competition. The remainder of our product is the hands of men who can hold it indefinitely.

Los Angeles, Cal., Sept. 7.

How Do Bees Manage to Survive the Winter?

By “An Observer.”

Bees survive the winter by packing themselves in clusters between combs of waxen cells filled with honey.

The low temperature a cluster of bees so situated can resist and still keep alive is really marvelous, and is only paralleled, in the other extreme, by the degree of heat a beach without sand, and with 70 per cent. humidity, that although some heat must be lost, the loss through the combs may be reckoned as nil. The cluster loses heat around the outer circle, at the periphery; the circumference is the radiating and cooling area. In the case of a cluster of bees, say 10 inches in diameter and ½ inch thick—about the distance between the combs—we find that the cluster would be very nearly 40 cubic inches in volume, and the radiating or cooling area would be 15½ superficial square inches; three cubic inches of bees, therefore, only expose to the cold a little over one square inch of surface. If we take a cluster 5 inches in diameter we find the volume to be 10 cubic inches, and the radiating surface or area 7½ square inches; and, if we take a cluster 4 inches in diameter, the volume would be 6½ cubic inches and the cooling area 6½ square inches. The 10-inch cluster has therefore, three times the advantage of the 4-inch cluster, and, in proportion to volume, three times more heat will be required to keep up the temperature of the smaller cluster.

The calculation of volume to cooling area may be shown thus: It would take the bees contained in four clusters of 4 inches in diameter to make one cluster 8 inches in diameter, and the cooling surface of the 8-inch cluster would be one-half of the cooling area of the total of the four separate 4-inch clusters. The heat required for the larger cluster would require only one-half the heat to keep up their living temperature that they would in the smaller clusters.

If we take a cluster one inch in diameter the volume would be half the 4-inch, say four-fourths of a cubic inch, and the cooling area the half of 3.1416, say 1½ square inches; the cooling area is, therefore, proportionately four times greater than in the 4-inch cluster, and is too large to allow of much fall in temperature with safety to the bees. So small a cluster could not exist in winter, except at the equator or near to it.

The individual bee is very sensitive to cold, but we must remember that a cubic inch exposes 6 square inches of surface to cooling air. If the cluster heats up above 54°F., it will increase as the cube, and the surface as the square. A bee in mass or volume is less than the sixty-fourth of a cubic inch, and its radiating, cooling, or heating surface is more than one-sixty-fourth of a cubic inch. If the temperature of a fourth of a cubic inch to be a cube, its surface would be three-eighths of a square inch. This cube would therefore expose a radiating surface proportionately twenty-four times greater than the cubic inch of a bee.

A well-formed 10-inch cluster, must be afforded over sixty times more protection from cold than it would possess outside the cluster.

The space between the combs is important. We will consider the distance between the combs in reference to the cooling area, and at the same time the supply of food, as these are closely related. The 10-inch cluster, between combs ¼ inch apart, is surrounded by 80 cubic inches of honey—supposing the cells in each cluster to weigh 0½ of a pound there are 4 pounds of honey within reach of the cluster for the bees to feed upon. We will now suppose the combs to be one inch instead of ¼ inch apart; the bees clustering close would occupy only 5½ inches on each side, the corresponding 10-inch cluster would require 60 cubic inches of cooling area, which is too large to remain with 80 cubic inches of honey within reach of the cluster for the bees to feed upon. The space between the combs must at all costs be maintained, and the food must be supplied in such quantities as to remain with the bees during the cold.

When the depth of the combs allows the bees to locate their stores above the brood-cells, they always store the store-cells so as to leave only ½ inch space between the combs. Let us suppose that the bees contain 10 pounds of the finest honey, containing 12 per cent. moisture. Taking the 4-inch cluster between combs ½ inch apart, it would have to extend itself to nearly 5½ inches to remain in the same volume at the ½ inch distance. The cooling area would now, from diminishing the distance—be 4½ square inches. The immediate reach of the bees would be increased, from 2 cubic inches to the cubic inch of bees, to 5 cubic inches to the cubic inch of bees—that is, 150 per cent.

Considering the facts above, I think it is evident that the size of the cluster and the depth of the combs are the essential requisites for wintering, and that, as a general rule, the size of the cluster and depth of combs must increase in size, they must, of course, be diminished in number, and if the construction of the hives should not
admit of the requisite sized combs for the latitude in which they are to be used, the bees will not be able to winter successfully in them.

The fecundity of the queen, so far as we know, does not vary with the latitude and can not, therefore, be brought to bear on the subject in regard to the general area of combs used.

The bees survive through the winter by preserving as well as they possibly can the heat of their clusters; and as the general interior temperature of the hive can only be raised to the loss from these clusters, it follows—paradoxically, as it may appear—that the colder the general interior of the hive the better are the bees wintering, through the preservation of heat in their clusters; and it also follows that upward ventilation, or draught, through the hive is prevented—which draught the bees dread above all things—the entrance to the hive can not be too large.

In the spring, however, when the bees extend from the cluster over their combs, warmth in the general interior of the hive is an advantage; but if great enough to cause the bees to leave the clusters too soon, it might be productive of more harm than benefit.

The controversy concerning the merits and demerits of cold and warm hives by the presentation of the above facts is at an end. The main object to be considered is their construction to admit of combs adapted to the size of bee-clusters required in various latitudes.—British Bee Journal.

No. 2.—A Bee-Keeper's Vacation in Wisconsin.

BY C. P. DADANT.

FRIEND reader, last week I left you after telling you a fish story, yet I have no doubt that you wish you had come along with me when this was caught. But this happy neighborhood has other attractions besides good fishing, for they tell me that there are both deer and bear in the woods around Sturgeon Bay. I was rather inclined to doubt the existence of the latter in a section already wooded, but I can not help the fact of having a acquaintance with the lady who accompanied us showed us the spot where she had been badly frightened by the appearance of a bear while walking along the road. "And," said she, "though I turned to run, the bear was as badly frightened as I was, for he also turned and ran in the other way."

The woods are indeed wild, in spots, more brush than timber, for all the good timber has long ago been cut, and mankind sufficiently powerful at the time our ancestors had not been despoiled by human wastefulness. The thicket is so dense that it is, in some places, almost impossible to get through, and they say that in the deer-hunting season it is not wise to travel about in those woods, not on account of the bears, but on account of the careless hunters who are apt to shoot at anything that they see moving in the thickets, before they have ascertained what sort of game it is.

These woods are in all sorts of evergreens and many deciduous trees, chief among which are the beech and birch. There are also shrubs, blackberries, and the inevitable red raspberry, which I am told exists all over the North, clear up to Alaska and the Klonidke. This is certainly a very nice thing, and the forest fires have destroyed what the raspberry is half as fragrant as the wild berries themselves, it must be delicious. But it may be with this as it is with the early fruit-bloom in Illinois, perhaps the colonists could have saved it from the ax. When the first settlers were made, the main puzzle for the white man was how to get rid of the wood, and we can still see traces of an awful waste of timber that would now be valuable. I saw a small apiary in an enclosure made of trees two to three feet in diameter. Two logs had been rolled side by side, and a third one put on the top of them, making a barrier about four feet high and four feet in diameter at the base. Of course this fence was old, probably 25 years or

more, but it was still sufficient to keep out stock, and stood as a witness of the haste with which people destroyed the forest. May we not, as a nation, be sorry later on, for not having retained at least a part of our countryside.

The pine timber is getting more expensive, and experienced lumber-men predict that within ten years most of the pine will have to be purchased in British America. Already most of the timber on the shores of the big lakes has been cut over, even on the Canadian side, and although many and many a boat-load is seen coming southward towards Chicago and the big centers, yet the quantity is less than formerly. Some saw-mills are cutting only hemlock, such timber as was considered worthless 20 years ago.

But the destruction of the forest does not seem to injure the bee-industry, for if many wild plants are thus destroyed, it is there as in our prairie States, many of the cultivated plants are honey-yielders, and the white clover especially gains a foothold wherever cattle graze. So the prospect is rather for an increase of honey-production than for a decrease. And the Golden Age, in a country "flowing with milk and honey," is certainly more in the prospective future than in the past. In all these hills that have seen the Indian disappear when the white man came.

But, dear reader, it is now time to go home, and our vacation is coming to an end. At ten o'clock, Monday morning, the whistle of the "Chicago" boat announces to us that she is at the dock, waiting for her passengers, and we are leaving for the next adventure, and embark.

"Grandpa" Dadant, who is to stay till the end of September, accompanies us to the boat. In another hour we pass through the Ship Canal, and are afloat on the blue waters of Lake Michigan. We give you here with a view of one of the many sights we encounter—a tug drawing three sailships loaded with lumber, bound for some southern port. This view may be familiar to many of our Chicago friends, but it surely interest our prairie bee-keepers, who have no occasion to visit the lakes.

On the second day of our trip we had a little storm, just enough to give our ladies an idea of seasickness, and its pleasures (?)—but this was soon over, and gave them just that much more appetite for a hearty supper in a Chicago restaurant.

When we arrive in Chicago, the romance is at an end. There is nothing left but noise and bustle, smoke and dust.

No, no, don't talk to me of Chicago! We hurry home as soon as we can, barely taking time to pay a short visit to our worthy friend, Mr. York, the kindly editor of the American Bee Journal. In a few hours, through smoke and dust, we are again at home, resuming the daily duties of life.

Hancock Co., Ill.

"The Hum of the Bees" in the Apple-Tree Bloom is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hammer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at $1.00.
Convention Proceedings.

BY LOUIS SCHOLL, SEC.

The seventh annual meeting of Central Texas Bee-Keepers Association was held at College Station, Tex., July 22 to 26, 1901. It was really a joint meeting of the Central Texas, North Texas or Texas State, and South Texas Bee-Keepers' Associations. The three were consolidated into one, viz: "The Texas Bee-Keepers' Association," with new officers elected, and new constitution and by-laws adopted.

The meeting, in general session assembled, was called to order by Pres. O. F. Hyde, of the Central Texas Association, July 24, at 8 a.m., with Pres. Stachelhausen, of the South Texas, and J. M. Hagood representing the North Texas Association, in the chair; Secretary E. J. Aten, of the South Texas, and Sec-Treas. Louis Scholl of the Central Texas, at the desk. Pres. Hyde spoke briefly on the honey-bee, after which Mr. Aten offered prayer.

The presidents next made their reports, followed by that of the secretaries, each giving an account of the standing of their respective organizations. Next, the election of officers of the Central Texas Association ensued, and resulted in electing, for the ensuing year, J. B. Salyer, president; H. H. Hyde, vice-president; and Louis Scholl re-elected Secretary-Treasurer.

The call for new members was ordered postponed, as a committee appointed by the chairman, on constitution and by-laws, was to make its report at the afternoon session. This committee consisted of Louis Scholl, H. H. Hyde, and F. L. Aten. Then the regular subjects on the program were taken up, E. J. Aten speaking on Bee-Keeping for Farmers.

He hardly knew whether to encourage farmers to keep bees or not. He mentioned some of the things he had seen at a neighbor's, who was a good farmer, trying to keep bees, and making blunders. If they would only keep a few colonies, and produce only enough honey for their own use, it would all be right. When keeping more, and during an extra-good year, they have a surplus, which they rush to a town, lump it off for any old price, and it being mostly honey of an inferior quality, besides their not being informed in regard to the price of honey and the condition of the market, never reading a bee-journal, they run down the price of honey, and are ruinous to the experienced bee-keeper, who is in it to earn his bread and butter; therefore, Mr. Aten said, it should be discouraged.

J. M. Hagood is in a strictly farming district and is a farmer. He said that the farmers ought to encourage the bee-keepers to keep bees for the good purpose of fertilizing the flowers. He has his home-market and sells most of his honey there, so the effect of the farmers' ignorance and inferior honey, containing old, dark combs with pollen and such, has ruined his market and lowered the price.

G. F. Davidson moved that we invite Prof. Mally, State entomologist at the A. and M. College, to speak before the bee-keepers at the afternoon session, in regard to assistance from the bee-keepers in going before the next special session of the legislature in August, asking for an appro-
piation sufficient to help cover the costs of establishing a department for the study of bee-keeping, and the location of an experimental apiary on the grounds. After some discussion concerning the great need and usefulness of such a project, it was decided that the work be attempted, and while accomplished, the motion was unanimously carried, and a special committee appointed, composed of H. H. Hyde, G. F. Davidson and R. C. Knowles, to invite Prof. Mally to come to Minnesota and give a course in bee-keeping. Prof. Mally, and to go to Austin (Texas) before the legislature, was appointed, viz.: G. F. Davidson, Louis Scholl, J. M. Hagood, and E. J. Atchley. The subject under discussion was then resumed. Z. S. Weaver said that bee-keeping must be followed altogether as a business. He does not encourage farmers to keep bees, but many would be here now as bee-keepers if not started on their farms. It just depends whether the farmer is the one who should follow, and course the one not the best paying is turned loose. Some keep bees as a side-issue, become enthusiastic and succeed, while others fail. If the farmers keep a few colonies of bees, for their own use, it is all right; otherwise it is not.

O. P. Hyde makes a whole business out of bee-keeping and keeping bees for the dollars and cents there is in it; he has no objections at all to farmers keeping bees, for if he had 100,000 pounds of honey at his home, not 1000 pounds of it would be sold, and his market in North Texas. Just let farmers keeping bees go on, and the matter will adjust itself some way in the future.

Mr. Atchley objected, as new ones coming in all the time the matter could not adjust itself, but must be done by the experienced bee-keepers discouraging the kind who won't succeed.

There were many who gave their opinion in regard to this matter. Some said it was not a good idea for farmers to be a bee-keeper or a farmer; they cannot be made to harmonize, as the bees need one's whole attention to make them successful, and either the farm or the bees must be neglected some time, especially in the spring. At the time the bees need attention, the farm needs it; and as nobody can be hired to attend to a business as one himself would, something will be neglected. And what is the use of only half attending to each, instead of following the one most suitable? There are many sections most excellent for bees but not for farms; others just the reverse. Then, again, there are men more fit for one than the other. This ought to govern as to which line should be followed.

The discussion ended, that if farmer bee-keepers would keep bees in the same way as a profession, their honey, using the latest methods, putting it up for market rightly, and keep informed in regard to the market price of honey, by reading the bee papers and books to keep up with the times, they would have an excellent business. A bee-keeper, as the more experienced to teach them all this. Encourage such as will succeed and will try to make a success at it. But the others that can't be taught, won't read a bee-paper, won't turn in with their inferior stuff, to lump it off at any old price, should be discouraged in any way possible. Bees really belong on the farm as well as poultry, hogs, cows, and such, and should be kept, but rightly kept.

PRODUCTION OF CHUNK COMB HONEY.

This was next taken up, on which M. M. Faust gave his method of production, and disposing thereof. He wants the strongest colonies for producing all kinds of honey, but more for bulk comb honey. He lets them get strong and gives them proper quarters, adding a super with shallow frames containing foundation starters one-half inch wide. If the bees are slow to go up, he puts on another half-depth super, putting up some frames of honey from another super if necessary. He adds the shallow frames in their stead, until well started, when numbers are readjusted. He used to produce about one-half extracted and one-half of bulk comb, but the past season he has had too much to fill up by comb-honey cans. By giving all frames containing foundation, he has had some trouble by the queens depositing eggs in the supers.

O. P. Hyde followed with a good paper on this same subject. In its different phases, this subject would naturally divide itself into these three parts, viz.:

1. How to produce bulk comb honey.
2. How much more bulk comb can be produced than one-pound sections?
3. Why should we produce bulk comb honey?

On the first part, have all your bees in 10-frame dovetailed hives of standard size; Italian bees, and robbing colonies. Then when the flow begins, he puts on one "Ideal" or 5½-inch-deep super with 5½-inch-deep frames filled with full sheets of extra-thin foundation. By using full sheets of this foundation the bees enter the super once, and it will not be detected in the honey. When the first super is about half full, another is put under it, and so he keeps on tiering-up. He gives plenty of room and sometimes as many as four or five supers on his strongest colonies.

The above size of frame is preferred, as when one is full, it will just make a complete layer in the five-gallon eight-inch-screw-top 60-pound cans, when cut in two in the middle and laid up 2½ inches thick.

The advantage of shallow frames over full-depth frames is that more capped honey can be obtained.

Secondly, he asserts that twice as much bulk-comb can be produced as one-pound sections, believing that he can prove it. The bulk open frames more quickly, work harder, and almost fill two supers as quickly as one section super. Also, the advantage of the extra amount of extracted honey that goes in at comb-honey rate.

Thirdly, the keeping of bees from the dollar-and-cent standpoint, wanting the largest return for the money, the bee-keeper must produce the kind of honey that sells the quickest and gives the best results. If his customers were wholly or mostly for section honey, he would be forced to use one-section supers; if the market is for bulk honey, if extracted, then it would be extracted. As it is the demand that keeps us in the market, we must produce the kind there is a demand for.

He was once an advocate of section honey—the kind that has a thin strip of wood around it, thinking it so nicer that he would not have anything else. He is still an advocate of comb honey, but the kind that is cut from the frames, placed in cans and that delicious, sweet extracted poured all over it. Then you have not only extracted on the inside, but on the outside of the comb also, which makes it more desirable to the taste. When he was for sections, the Northern brothers said he was a practical apiarist, but now he is for bulk-comb, and they say he has retrograded 20 years, which, however, does not matter with him, for he is not for popularity, but for the dollar.

He also gave some figures and some idea of the immense quantity of such bulk comb honey that is in demand here only a year and a half ago.

A question was asked in regard to keeping it over winter, whether it would granulate, and if it could be taken out in layers then. The answer was that this was the only drawback that bulk comb honey had, but the demand for it is greater than the supply, and the price of honey has not been so high as to discourage, hence none is kept over winter to become granulated.

Mr. Davidson seriously criticized Mr. Hyde's paper, saying that he did not want it to be understood that the production of section honey should be as-sailed in any way, and that the production of sections should not be discouraged; besides, the production of fine section honey stands above all others, and is the highest art of producing honey. He intimated that the reason why they were not producing section honey was because they did not know how; and that the day will come when more section honey will be produced than bulk comb, as it is the more wealthy people, anyway, that eat the most honey.

All three grades are good, but fine section honey can not be procured during slow flows, as it takes fast, rushing flows, and a locality with such. There is just as much in dollars and cents to be made with section honey as bulk comb, and the former should be encouraged. O. P. Hyde ended the discussion by saying that he was not as much discouraging the production of section honey; that he is willing to produce only what is in greatest demand, and gives the greatest profits. He is not pushing this, but it is his customers that impose it on him.

Before adjournment, H. H. Hyde moved to appoint a committee of three to judge the bee-keepers exhibits, and these were named: D. C. Milam, W. O. Victor, and Mrs. C. R. West.

Adjourned for dinner, until 2:30 p.m. (Continued next week.)
Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, III.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, who will answer them as far as possible. Please do not ask the Doctor to send answers by mail.—Edtr.)

Combs Melting Down—Swarming Mix-Up Transferring, Etc.

Replying to J. A. Gerald's page 567, I think he has made the right guess in concluding that the combs melted down in his hive because the dense growth surrounding them prevented the free passage of air. I never yet had combs melt down when hives stood in the full blaze of the sun, but one year I had a few cases where the hives were in dense shade all day long. A dense growth of tall corn was on one side of them, and close bushes on the other.

In reply to S. B. Smith (page 573), he has no doubt made a close guess at what transpired. Of course it can only be a guess, but I should put my full guess in this way: The young queen in No. 11 went out on her wedding-trip, accompanied by enough bees to make the small swarm that was hived; the remaining bees of No. 11 then walked over to No. 15, thus making a mass of extraordinary strength. An item that tends to confirm this opinion is the fact that bees were seen going on the alighting-board from No. 11 to No. 15, and it is likely that close observation would show the bees doing that same thing two weeks later. The bees on coming from the field would not go direct to No. 15, but would enter No. 11, and then crawl across until that generation died off; at least a certain number of the bees would go through that performance.

T. E. Weaver (page 574), would like to know whether his plan of transferring would work all right in a poor honey-year. It would likely be all right except the danger of robbing, for if he should do exactly as appears from his description at any time when honey was not freely coming in, he might have a lively time of it.

Dr. Peiró (page 574), lays a very heavy burden on that poor little crack under the cover. You say, Doctor, that after seeing that crack your "conclusions were clear and rapid." Rapid, very likely, but it is somewhat doubtful about the clearness. A reasonably strong colony will not only guard a full-sized entrance in the ordinary place, but also an entrance equally large right under the cover. For a number of years I have been on the file of Agi-Itrim. I allowed, besides the regular entrance, an opening over the frames at the back end of the hive 15 inches by 1/2 to 3/4, and there was no trouble about the bees protecting themselves. If at a time when robbers were about the opening should suddenly be made under the cover, there might be a little danger of trouble, but if the opening were made in a time of plenty, there should be no trouble; and there should be no danger either in scarcity or plenty if the crack were made by the gradual warping of a cover. C. C. MILLER.

Perhaps Larvae of the Bee-Moth—Climbing Brood.

1. On Aug. 3 I made the first "drive" in transferring a colony to a new hive, supplying them with full sheets of foundation, and after they started storing well I gave them an Italian queen. I then felt lightly by putting a small dish of granulated sugar syrup under the frames at night, and removing the empty dish in the morning. At present they have six Danz. frames nearly filled, and two more started, principally from stores they had but a few days in the hive. Now the morning there will be young bees, sometimes to the number of 30 or 40 scattered around the entrance, ranging in color from clear white through all the shades and markings of brown, up to those which will be struggling to free themselves from the dewy entrance-board. What is the cause and cure?

2. Is there danger of chilling the brood by removing it from the hive in the morning of evening of cool days at this time of year?

I can find nothing on these subjects in my books.

I. L. ILLINOIS.

ANSWERS.—1. Looks like worms, or (begging Prof. Cook's pardon) the larvae of the bee-moth. They work their galleries through the cappings, and the larva of one kind work at the bottom of the cell. When very bad, the young bees will be dragged out as you describe. The remedy is to get Italian blood. Possibly, however, a fuller knowledge of the case might suggest some other trouble.

2. No danger when it is warm enough for bees to fly, unless the brood is kept out an unreasonable length of time. Ordinarily there is no need to have a frame of brood in the hands more than a minute at a time.

* * *

The Afterthought.

The "Old Reliable" seen through New and Unreliable Glasses.

By E. E. HASTY, Sta. B Rural, Toledo, O.

NO BLOOD BUT EGGS PRESENT DURING DROUTH.

Dr. Miller's experience in the great July drought—no brood either sealed or unsealed, but eggs always present—adds a crumb to a pertinent and interesting bee-fact which we have to figure with. Page 538.

PURITY IN MARKINGS OF PARENTS.

It sounds to me as if "Texas," on page 520, was after strictly three-handles and drones. Won't get em. Doubtful if they could be called any purer than the present ones if he did. He should remember that nature often differentiates the sexes remarkably. Sometimes it even occurs that the male is a winged creature and the female a crawling worm. Wild birds are our purer; but often the male is brilliant in colors while the female is plain looking.

"BURNING ONE'S OWN SMOKE."

Prof. Cook, on page 521, passes to us some important teaching aid in very pungent words—let us burn all our own smoke. Won't make quite so much smoke if we have the job of burning it in view. And what rent have we paid for our neighbor's eyes and lungs that we should warehouse our smoke in them? Don't forget forgetting that what we try to call entertaining conversation is sometimes the worst smoke we make.

MAKING ROOMS MOUSE-PROOF.

Mr. Foote is on the right track about mouse-proof rooms. Mice first get into the spaces between walls. From that vacuum ground they can make their way to cracks and lay plans to get there—would not so often dodge through doors had they not their minds made up previously that it was a good place to go. And usually, as we know, some little defect in plaster or base-board proves capable of enlargement. And in the process, finding an entry to the side of the building, and studs set on a narrow plank, would keep them out of the wall-spaces to start with, and so mainly prevent after consequences. Page 523.

WORKING HIS "STANDS."

How does he work his stands, Dear Boss? Why, he makes them lift. And if he makes his stand lift about 100 pounds more in August than they do in May, is it not all right? Virgil is praised because he called a bee-hole twelve different names and ever since I read Virgil (if not before) I have had a leaning in that direction—toward an elastic application of terms. True, lack of precision is a bad thing; but if Virgil fully filled his word with things that were too limited—too lean and bald. May we not all be poets to the small extent of having a little versatility to our speech? Let us not groan nor scold even if one comrade does catch a nice string while another catches a nice lot of ladies and another catches a dinner, and another catches a cure for sore eyes. Page 530.

THE LEGISLATION OF THE AUSTRALIANS.

Those Australians are continually solving things the rest of the world failed to solve—or failed to try to solve. We cannot very well legislate the aparian pig to his own end of the territory trough; but we can give him a "bar-basinster" by refusing him membership—and see whether his hide is so tough that he cares nothing for a blow of the nippers. Australians, American societies seem rather too nebulous to hit anybody, even to the small extent of refusing membership. Membership is anybody that happens to come to a meeting—and so few that the proposition to bar people out would seem gro-
tesque—last rose of summer forbidding the pips to bloom. Page 537.

**WRITING** **TT** **THINGS WHILE FRESH IN MIND.**

I also incline to “Amen” the plan of writing up things while they are fresh in the mind. Writer needs the help most even if it was a case of writer versus reader, which it isn’t exactly. Reader’s ears have been dug open by his experiences, and will have wax in them ten months hence. Also, if the would-be writer forgets a thing before it gets in print there is no back number to go to for it. Page 531.

---

**The Home Circle.**

Conducted by Prof. A. J. Cook, Claremont, Calif.

**THE TABLE.**

“Ah! but wasn’t that an elegant table?” That was my daughter’s query. We had just broken doughnuts with a good friend—one of those splendid women who is ever dispensing cheer and bonhomie. We all asked, First, the ladies was so entirely immaculate and of such proportions that it just seemed made for that special table. Each marginal inch seemed impressed by gravity just as strongly as every other, for none had reached down nearer the floor than had any other, and none had seemed to aspire to be a piece of art! The plates with accompaniments, each was like a well arranged bouquet. Nothing was crowded, yet there was no wide desert area, and we all said that room was found for a single lovely spray of wild roses. These were sweet over as a piece of art! Men like Gladstone could not have moved the world had any other course been chosen.

**CARPENTERIA.**

The ride on the “Espe” shore line from Ventura to Santa Barbara is charming. I took it to-night by moonlight. On one side the tall hills—beginnings of the Sierra Madre—hug close as if to shut all danger away. On the other, the breakers crashed and spurned the narrow rock ledge with the moonlight to gild all, it seems a fairy scene. Carpenteria—pronounced Car-pen-te-ra—a is a delightful littleburg about midway on this line. The word is said to come from the Spanish Carpenter, but several other explanations for its adoption. I like this one: The red-winged flicker or yellow hammer like the golden-winged of the East, except red replaces gold on the wing-feathers, is thick here, and the Spanish Carpenter, as all cognate to it, are several explanations for its adoption. One church is surely very “holey” because of this bird’s desire of entrance.

If we can trust to appearances at Carpenteria the bird is a Baptist. The worshippers there have been compelled to tie the church steeple, to keep the birds from making their nests. The bird is also a sap-sucker in California. He taps the walnuts, as does the real, genuine sap-suckers the various orchard and forest trees here and elsewhere. He is also unlike his close relative East—a fruit lover, for under any bird that once tasted California fruits would surely change its feast habits, and become frugivorous on the spot.

Like the other flicker, if we take this bird’s eggs away daily, she will lay as many as 90.

**SICK PLANTS.**

Do our plants talk to us? If not, let us get acquainted with them, and then they will. I love the poet Bryant. Isn’t he called the Poet of Nature? The plants in our garden are covered with dark green leaves, with their grace and grateful shade. The brooks sang for him, and to him; and trees, brooks, hills, mountains, sky and air, had their stories to which his ears gave fine attention. He wrote the great “Thanatopsis.” I read it so much to my children, that they learned the poem, and today my daughter loves Bryant most of all our poets. That he had a listening ear for Nature’s finest thoughts appears from the exordium of that masterpiece:

“Tobin who in the love of Nature holds communion with her forms.
She speaks a various language.”

The little child wakes before the day, and awakens our keener anxieties by his little “I’m sick.” As Day draws her curtains, we peer down to the little trundle-bed, and see the pallor that drove away pink and rose, and the “I’m sick” is spoken just as clearly.

My wife is anxious. The great, splendid sword-fen which is the glory of our parlor, tells her it is sick. It speaks in the yellowing tint of the leaves. As in all plant sickness. First, are there any insects? Does grub or caterpillar sap the roots, or scale or aphid the leaves? My wife is too wary to make that probable. We examine very carefully and find nothing.

Next the water. Has there been too little or too much? Work has learned to gauge the water. We decide the water has been right.

Then we add nitrogen, sodium nitrate or Chili saltpetter is excellent, and, all at once, as by magic, new green appears, life brightens, and our plant fairly sings, “I’m well again!”

Plants, like children, must be generously fed.
Standard Belgian Hare Book!

BY M. I. CAPPS.

This book of 175 pages presents a clear and concise treatment of the Belgian Hare industry; its growth, origin and kind; the sanitation and construction of the rabbitary; the rabbitry; selection of breeding stock; care of the young, feeding, diseases and their cures, scoring, marketing, shipping, etc. First edition of 50,000 copies was sold in advance of publication.

Price, in handsome paper cover, 25 cents, post-paid; or with the American Bee Journal one year—both for only $1.00.

100 Colonies of Leather-Colored Italian Bees For Sale....

From stock which took first premium at the Minnesota State Fair, 1901. All in standard hives, in fine condition, and with abundance of sealed stores for winter.

W. R. ANSELL,
S.W.T.
ST. PAUL, MINN.
Please mention Bee Journal when writing.

Bees Did Well.

My bees have done very well this season, and not much swarming. From one colony I took 100 filled sections of honey. We get very little dark honey.

JOHN GERTHOFER,
Onondaga Co., N. Y., Sept. 9.

From Two Washington Girls.

We have done so well in the bee-business this summer that we thought we would write again. We are going to send a picture of our apiary this fall.

By buying queens and comb foundation we increased from 7 colonies to 21. They have filled 234 sections. We ran out of sections, and so we put on empty supers and boxes. They have them nearly full of honey now. We get 10 cents per section, and could sell all we could produce at that price, even if we had 100 colonies, and that is what we are going to have before we quit. We wish you could see some of our honey. It is white, and of the finest quality.

EDNA AND ALICE YOUNT,

The "Jouner"—Queen-Excluders.

Permit me to join Mr. Davenport in commenting Mr. Martin's "Jouner." Noting reference to it in a recent number of the American Bee Journal, I thought it worth a trial in removing bees from cases of comb honey. The first attempt was so satisfactory that I thought about that "little bit of information was worth several years' subscription to the American Bee Journal, to any bee-keeper whose time is of value." It does not need a heavy jar, but a quick, sharp one such as may be given by a little practice. If Mr. Martin's cloth jar could be placed so as to be joined with the super or case, it seems to me that there would be practically no removing of bees. I use a little smoke before removing the case from the hive: a little
to make own pat. use Splendor Cream Separators, Book "Business Dairying" & Cat. 212 free. W. Chester, Pa.

DESKS FOR GENTLEMEN AND LADIES!

These desks are made of quarter-sawn oak, first-class finish, well put together, and will please every purchaser. They are an ornament to any home, as well as being a useful necessity. Would make a FINE GIFT for father, mother or sister.

The Combination Desk and Book-Case

is just the thing for a farmer or business man of any kind, to keep his private papers in, and for his books, etc. The drawers have locks, and there are a number of pigeon-holes inside each of the desks shown herewith.

The low prices quoted are f.o.b. Chicago. Send for free catalog. Address,

The Royal Star Combination Game-Board Co.,

773 to 779 Carroll Ave., CHICAGO, ILL.

Ladies' Desk.

Size, 40 in. high, 25 in. wide, 13/4 in. deep.
Price, $2.85.

[The above firm is entirely reliable.—Editor.]

Please mention Bee Journal when writing.
more at the top when or the mower, so as to drive the bees down, then by giving the case two or three quick jars, the bees are sent down all round, and one is saved hours of labor by this simple operation. Mr. Martin, thanks! I'm free, but I have only a quarter of an hour more to be of less importance to bee-keepers, and in regard to which there seems to be a difference of opinion, which I am unable to settle. It is that of queen-excluders over the brood-frames. I have never used one, neither for cut nor extracted honey. Sometimes the queen has gone into the surplus chamber when run for extracting purposes, but very seldom to a section-excluder as often in the supers. This year, after removing a large number of cases, I have found that the queen has been kept in two but two sections of the hundred taken from the hives.

I attribute this freedom from intrusion of the queen to the use of thin top-bars, which are not sufficiently spaced, so that only a bee-space is left between any two of them. I may be mistaken, but if my impression is correct, what a saving of time, money, and trouble, putting with zinc excluders.

By the way, say to Mr. Baker (page 549) to keep tally of the sections from the colony referred to. I have some long-tongued bees, and shall strive to be at least a "close second" when the season opens.

Kankakee, Ill. WM. M. WHITNEY.

A California Report.

I started the season of 1901, in March, with 210 colonies, increased to 250 colonies, and have taken off $1,200 worth of extracted honey, besides leaving the supers full.

J. A. OWEN.

Fairly Good Season.

The season was good until the drought set in in July, when the excessive hot weather eat the linseed floor short. I secured $900 worth of extracted honey, from 61 colonies, spring count, and increased to 110, which are in good shape for winter. All of my honey is sold in the home market. E. M. DOTY.

The Bee in California.

Bee-keeping in parts of California is not only a success but a real pleasure. The mild, temperate climate does not necessitate the careful housing of the bees, nor is it necessary to find food for them during the winter season. The colony is placed in that honey spot under some tree in the fence-corner. They have shade, and also a wind-break. Here they gather the nectar with which they feed. Men eat what they have eaten, and more eaten, the race would reap a rich benefit. This is no vague theory; it is a scientific truth.

The honey taken late in spring is sometimes the very finest quality. The locust blossom has given a generous contribution, and this is one of the finest honey-producers.

The honey taken in the fall is enriched by the alfalfa blossom, and also from the blossoms of the mullen-weed. This weed does not grow east of the Rockies, and is always close to the ground, and is of a very light-blue color. The honey-gatherers seek out its tiny blossoms with the same diligence that the bee-keepers seek out the abundant honey on the pastures.

Honey retails for 10 cents a pound, or two dollars a box. These boxes contain a pound of honey, which they sell for $2.50 when full. They do not have the frames, and the honey is not in a condition, as is the case with the honey made in frames.

Among the various other sources from which the California rancher may look for an income, he should give attention to bee-culture. He knows and keenly realizes that he can not depend any longer upon wheat at the low price of recent years, and, while he is looking after other sources from which to receive an income, he may do well to remember the bee.

Extracted Honey For Sale
ALL IN 60-POUND TIN CANS.

Allalfa Honey

This is the famous White Extracted Honey gathered in the Allalfa regions of the Central West. It is a splendid honey, and everybody who cares to eat honey at all can't get enough of the Allalfa extracted.

Prices of Allalfa or Basswood Honey:
A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Allalfa, 8 cents per pound; four or more cans, 71/2 cents per pound. Basswood Honey, 31/2 cents more per pound than Allalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are boxed. This is all

ABSOLUTELY PURE HONEY
The finest of their kinds produced in this country.

Read Dr. Miller's Testimony on Alfalfa Honey:
"I've just sampled the honey you sent, and it's prime. Thank you. I feel that I'm something of a heretic, to sell several thousand pounds of honey of my own production and then buy honey of you for my own use. But however loyal one ought to be to the honey of his own region, there's no denying the fact that for use in any kind of hot drinks where one prefers the more wholesome honey to sugar, the very excellent quality of alfalfa honey I have received from you is better suited than the honey of more marked flavor, according to my taste." C. L. MILLER.
McHenry Co., Ill.

Order the Above Honey and then Sell It.
We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.
The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we sell for but 60 cents; or we will send it with the Bee Journal for one year—for both for only $1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

A Foster Stylographic Pen....

This pen consists of a hard rubber holder, tapering to a round point, and writing as smoothly as a lead-pencil. The point and needle of the pen are made of iridium—substances of great durability which are not affected by the action of any kind of ink. They hold sufficient ink to write 1000 words, and do not leak or blot. As they make a line of uniform width at all times they are unequaled for ruling purposes.

Pens are furnished in neat paper boxes. Each pen is accompanied with full directions, sealed in an envelope.

BEST MANIPULATING PEN ON THE MARKET.

19,000 Postmasters use this kind of pen. The Editor of the American Bee Journal uses the "Foster." You should have one.

How to Get a "Foster" FREE.

Send two new subscribers to the American Bee Journal for one year, with $2.00; or send $1.00 for the Pen and your own subscription to the American Bee Journal for one year; or, for 1000 words, fill the pen alone.

AMERICAN CHICAGO, or,

This is one of the standard books on bee-culture, and ought to be in the library of every beekeeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son.

Size of Queen-Rearing Nuclei.

Efforts have been made to use as small a number of bees as possible in queen-rearing nuclei from the time the young queen emerges until, but it is possible that the waste of a larger number of bees is not so great as might be supposed. Dr. Miller says in gleanings in Bee Culture:

"The greatest part of the cost of rearing a queen has been considered the time occupied in it. Stir this into the mixture thoroughly by running the extractor for several minutes longer.

In handling the naphthol-beta solution, be

Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for $1.25, or club it with the American Bee Journal for one year—both for $1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with $3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

CHICAGO, ILL.

HONEY AND BEESWAX
MARKET QUOTATIONS.

Chicago, Sept. 18.—No.1 white honey is selling at 15 cents per pound, with occasionally a little more being obtained for fancy, which is selling at 20 cents per pound. We quote dark honey of the grade 12½c; dark with the lighter amber at 12%-13c; dark honey of the grade 5c higher. We have from California buyers in moderate demand at from 5½c to 6½c for the various grades of whites; some fancy white clover honey bringing 11c; light honey selling from 5½c to 6½c; white clover honey bringing 8½c per pound. We received copyrights from Messrs. S. C. & W. BENT & CO.

Cincinnati, Aug. 10.—The honey market is rather dull on account of the warm weather. Extracted sells only to manufacturers from 6½c, better grades alfalfa water-white at 7½c; white clover from 8½c. Fancy white clover honey sells from 13½c to 14½c.

C. H. W. WERR.

Boston, Sept. 14.—Honey is coming forward in fair quantities and the demand is good, considering the warm weather we are having. Strictly fancy in cartons weak at 11c; A. 11½c, & No. 1 18½c. We have large quantities received.

BLAIR & SCOTT & LEE.

Albany, N. Y., Sept. 15.—We quote: Fancy white comb, No. 1, 15c; No. 2, 11½c; mixed, 13½c; No. 1 backward, 20c. We have large quantities of alfalfa honey. The production of honey seems to be quite large this year in Colorado, Utah and California.

PECKY BROS.

New York, Sept. 10.—Comb honey is now beginning to arrive in large quantities, and, as a rule, is in fair condition. We quote fancy white, 18½c; No. 1, 12½c; No. 2, 10c. Barren wheat is on the market as yet, but we are expecting some in a week or two. Extracted is selling slowly, with plenty of supply, at 5½c, according to quality, and Southern in barrels at from 5½c per gallon. Beeswax dull at 20c.

HILDEBRAND & SZELEKIN.

Des Moines, Aug. 7.—There is very little demand in northern markets for honey, and the lots of nearby produced comb honey are on the market and selling in a retail way at 80c to $2 per case. There are few prospects at present of any large demand in this line before Sept. 1. Our market does not consume a great deal of extracted honey.

PECKY BROS. & CHARTY.

Detroit, Aug. 12.—Fancy white comb honey, 16½c; No. 1, 13½c; no dark to quote. Extracted, white, 66c. Bee supplies small.

M. H. HUNT & SON.

Buffalo, Aug. 18.—Quite a good demand for fancy honey, 10½c, and lower grades, 12½c; old neglected. A fine moderate supply of new as yet.

BATTISON & CO.

San Francisco, Sept. 4.—White comb, 10½ 12 cents; amber, 78c; dark, 68½c. Extracted, white, 21c; amber, 40c. Beeswax, 260@2c.

Amber and white honey are of rather moderate volume, but there is as much or more on market than can be conveniently or advantageously placed. In general, black honey is in good demand, but the custom, prices would have to be shaded in favor of buyers. In a small way for especially desirable lots slightly higher figures than quoted are realized.

KANSAS CITY, Sept. 14.—Up to the present time there is a small lot of honey on the market, and these meet with ready sale. We have been quoted from 7½c for fancy honey and 10½c for black white. For next week heavier receipts are expected and quotations are issued at $1,100@$5.25 per barrel for large lots; the market would be firm at about 14@14½c; the demand being quite brisk. A firm market is anticipated. Extracted are a little more numerous, but large buyers still seem to have their ideas too low, in a small way 5@6c is quoted.

PECKY BROS.

RED CLOVER QUEENS

BLACK ROCK, N. Y., Sept. 3, 1901.

FRIEND ERNEST—I will try and tell you what you want to know about that queen. I got her of you in 1899 as a premium with GLEANINGS. I never saw a small colony of bees build up as that one did. In the spring of 1900 they came out in fine shape, wintered perfect. I raised them up in May and gave them 8 frames more so the queen would not want for room. I never saw such a colony of bees as they were in June, and they were actually storing honey when other bees in my yard were starving. No! they were not robbing. I never saw those two best colonies of mine trying to rob. THEY CERTAINLY WORK ON RED CLOVER. This is no guesswork, as I have seen them. As you know, the past two seasons have been very poor, and what honey my bees did get in 1898 candied so after cold weather set in. I packed this colony in a cliff hive and left them out, thinking that such a strong colony would winter perfect. The snow came on the middle of November, and those poor bees never a fly until the last of March or the first of April. When warm weather at last came I thought they were dead, as they did not seem to be flying much, so I did not pay any attention to them until in June. I noticed they were working a little, so I opened up the hive and found them in the upper story. I took the lower story out and left them in the one body. The queen was laying nicely, and I thought they would make a good colony to winter. Along the last of July I noticed that they needed more room. I gave them a super, 4 boxes, and in a few days they had filled it. They have made 72 boxes of as nice honey as you ever saw, and are drawing out some starters now, Sept. 2.

Very truly yours,

Geo. B. Howe.

Prices of Red Clover Queens.

MEMBERSHIP DUES. 1.00 a year.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

Note.—One reader writes: "I buy every reason to believe that it would be a very good idea for every bee-keeper to wear one (the buttons) as it will cause people to ask questions about the business, and many a conversation that started would wind up with the sale of more or less honey. At any rate, it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it. Price, by mail, 6 cents; two for 10 cents; or 6 for 50 cents. Send all orders to the office of the American Bee Journal.

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

THE AMERICAN BEE JOURNAL

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for $1.25, or club it with the American Bee Journal for one year—both for $1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with $3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

HONEYVILLE, O.

HOWARD M. MELBEE,

[TOP CUT IS THE FULL SIZE OF THE KNIFE]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plated brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a life-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having same and address of owner, the finder will return it, otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of these "Novelty," your Pocket Knife will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more touching memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a fair idea, but cannot truly convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for $1.25, or give it as a premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with $3.00). We will club the Novelty Knife and the Bee Journal for one year, both for $1.90.

GEORGE W. YORK & CO.

St. Chicago, Ill.

#4 Please allow about two weeks for your knife order to be filled.
A Bee-Keepers’ Paradise is what Editor Root calls Uvalde Co., Tex., with some other counties in that State and New Mexico. But after having raised the expectations of prospecting bee-keepers to the highest notch, he lets them drop with a dull thud by saying that Uvalde county is “alarmingly stocked.”

The Buffalo Convention Report we expect to begin publishing soon. There were no papers read except at the joint meeting of the pomologists and bee-keepers on the last evening. So, practically, the whole of the report will be discussions of questions. This should make it very interesting reading.

Hive-Covers.—Saw-kers on the underside of hive-covers have been successfully used to prevent warping, but Editor Root says that after a thorough trial of such covers they have been abandoned, because in dry climates these saw-cuts favor checking and splitting entirely too much. Even in northern Ohio they give a good deal of trouble.

Need of Laws on Bee-Diseases.—On page 631, Hon. J. M. Hambaug, bee-inspector for San Diego Co., Calif., offers some highly important suggestions that should have earnest consideration.

The careful, up-to-date bee-keeper deserves to be fully protected from his careless, slipshod neighbors whose bees are more likely to contract deadly disease, and when once contracted is harbored and permitted to contaminate surrounding healthy apiaries. Surely, there should be stringent laws in every State to compel every bee-keeper to aid in the discovery of bee-diseases and when found aid in its complete eradication. This is as much in the interest of infected apiaries as healthy ones.

Mr. Hambaugh also calls attention to the necessity of issuing a certificate from a lawfully appointed inspector, showing the healthy condition of every colony proposed to be removed from one locality to another. This certainly would be a wise provision. It would help in many instances, no doubt, to prevent carrying contagion from place to place.

Mr. J. M. Rankin, Michigan’s alert inspector, has just had an experience in the direction indicated. He examined a lot of hives, combs, etc., belonging to a bee-keeper at Evart, Mich., and finding ample evidences of foul brood, he officially ordered the bee-keeper to destroy the disease-infected combs, etc. Instead of obeying the officer of the law, he loaded the stuff on a car and shipped it to Clyde, Ill., near Chicago, where it will likely become a menace to the healthy apiaries in that locality.

Now, if Illinois had a foul brood law, and an efficient inspector, this case would be followed up, and finally be gotten rid of.

But what kind of a bee-keeper is the man that would ship bee-disease from one State into another, instead of destroying it, especially when ordered to do so by one whose duty and authority it is to clean up such disease before it is spread any further? The offending bee-keeper deserves the severest condemnation possible by his fellows, and also the complete destruction of his whole apiary if even the slightest trace of foul brood is found therein. Any man who would so wantonly convey disease from place to place, rather than obey a wholesome law, should be held up to the scorn of all good bee-keepers and citizens, and be made to feel to the fullest extent possible the result of such wilful disobedience.

We hope that there may be sufficient agitation to secure the much-needed laws in all the States for the protection of bees from contagious diseases. In view of the good work already done by the few State, county, and province inspectors of apiaries, it would seem that every State would be able to secure at least one inspector by the passage of a suitable law.

The Hive-Tool that suits best at Medina is a putty-knife, says the editor of Gleanings in Bee-Culture, while Dr. Miller says the Muench tool is away ahead of any other tool he has ever tried. Its broad semi-circular blade is easily wedged in under cover or super without marring the wood, and the other end is so constructed that a slight twist forces the frames apart with the exertion of very little strength.

Red Clover Honey.—A conversation is reported in Gleanings in Bee-Culture which is supposedly based on fact, from which it appears that a neighbor of G. M. Doolittle’s, living two miles distant, finds red clover perfectly fit for brood for the first time in 15 or 20 years, and his black bees are not to be seen on it at all, while Mr. Doolittle’s yellow bees are just swarming on it. From some colonies Mr. Doolittle took as high as 80 one-pound sections of red-clover honey, while the average yield was not far from 65 sections. The likening came, and made the total average from colonies not interfered with by queen-rearing about 145 sections, the highest average he has had except in 1877. It would be just like him to say that he now places a higher value on long tongues than he did.

A Special Enencoragement in Queen-Rearing lies close neighbor to the discouraging fact that we have little or no control of the drones. In order to stimulate to greater effort, it may be well to bring out with some minuteness wherein this encouragement lies. While it is true that drones from neighboring apiaries may meet our young queens, yet where one has a hundred colonies or more, especially if neighboring bees be few, the predominance in numbers of the drones in the home apiary makes the chance fair for some degree of safety from outside interference.

Let us suppose that we are so situated that outside interference of drones need not be taken into account. Suppose, too, that after close watch and careful record we have found one queen whose workers show marked superiority as honey-gatherers. All the better if the queen be of such age that such superiority has been shown in two or more years. The parents of this queen have had characteristics that made such a combination as to result in an offspring superior to either of the parents. Let us call the drone father of our present queen D1, the queen mother Q1, and designate their drone and queen offspring respectively as D2 and Q2. From our superior queen, Q2, will be reared the present season drones and queens that we will call D3 and Q3, and it will not be a difficult matter before the close of the season to have a Q4 queen in every colony in the apiary. Next season will then open with an apiary headed by Q3 queens, whose workers will be from fathers that vary from each other, hence the workers will be of varying value, none of them perhaps coming up to the mark of the workers of Q2, but taking the apiary as a whole there will be a noticeable improvement.

Now, as to the rearing of queens next season. If our superior queen Q2 is still living, and we are willing to take the risks of inbreeding, we may rear queens from her, or we may obtain a good queen of unrelated blood from elsewhere. In either case, the drones that meet our young queens will be the same, the sons of the Q3 queens, and may properly be called D4. Right in the character of those D4 drones lies our special encouragement. As parthenogenesis prevails among bees, these drones will not be of the same blood as the queen and worker progeny of their mother, but will be of the same blood as the Q3 queens themselves, and consequently of the same blood as the worker progeny of our superior queen Q2. Whatever superiority may have
been shown in the worker progeny of that queen, we have that same superiority in the drones with which the entire apiary is now stocked. Some claim that it is more important to have good drones than good queens, and no one denies that the drone is as important as the queen. So whatever the quality of the queens reared next year, we are in no danger of losing quality.

As already intimated, all this must be discounted by the chance of inferior drones from outside, but after making that discount there is still food for much encouragement in the thought that only superior drones are in our own yard.

The Best Fumigator.—A Stray Straw in Gleanings in Bee-Culture says:

If it is true that bisulphide of carbon will kill moth-eggs as well as larvae, why is it not a long way ahead of sulphur for those who fumigate their sections? Bisulphide can be used for fumigating for the short time of a month or within two weeks, and save the repetition of the fumigation that sulphur requires, also saving them, when there is no longer a danger, fumigation with sulphur.—[If the reports are true, the man who persists in using sulphur in place of bisulphide of carbon is far behind the times. The bisulphide is more thorough, and much less trouble to use. While it is subject to occasional fumigation, it is a danger for some time after应用, the burning of sulphur, even in an iron kettle, also has its danger.—Editor.]

But even bisulphide of carbon may have to give way to gasoline, according to J. B. Rapp, who says in the same periodical:

I have just made an important discovery, to me at least; that is, that gasoline is as effective in killing moth-worms in bee-combs as bisulphide of carbon, and it does not cost a twelfth as much. My plan is to fill a tight box or barrel with combs, then pour in a pint of gasoline; close up tight for 24 or 36 hours, and the work is done. Gasoline beats sulphur far away, and is much easier used. If used correctly, hundreds of Langstroth combs, and have no trouble with worms. As I think the gasoline kills the eggs as well as the worms.

The editor adds that he knows gasoline can be used in place of the more expensive drug to destroy ants, but it takes a larger quantity.

The Production of Beeswax.—Mr. Harry Howe thinks there may be profit in producing wax instead of honey in Cuba. He says in Gleanings in Bee-Culture that in the olden time many spicies were run entirely for wax, the honey being thrown away. At present wax brings 9 times as much as honey in Cuba, and the conditions are peculiarly favorable there for the production of wax, the honey-flow being eight months long, with hot enough nights during half that time for secreting wax without waste of heat. He says:

My plan is to cut out the combs instead of extracting the wax, but only half from each hive, extracting the other half so they will at all times have store-corn, and not longer a surplus to be had in the fields, contract the brood-nest and set out honey at one side of the frame. By July 15 they will be set aside, at a glance that both the quotations the American Bee Journal is able to be reliable for this reason—you are quoting one specially! In the trade journal, honey is but one of a great many, and for this reason will not warrant the time and energy of the American Bee Journal in a position to give.

By referring to the instance mentioned in Mr. Wm. Wilts' letter, it will be seen that it comes during the inactive period of the year; while if reference is made to the issue of Sept. 5, it will be seen that the lowest quotation is Aug. 6, and from that to Aug. 22, during which time we venture to assert that there could be no essential change in any market.

We might mention that in our business we have had occasion from time to time to write to different markets when for any reason our market happened to be short of supply, and this invariably found that we were unable to buy at a lower price than prices quoted; thus proving the correctness of the quotations, and certify to the value of the American Bee Journal to our shippers.

Wishing you continued success, we remain, Yours respectfully,

BLAINE, SCOTT & LEE.

We should be pleased to hear from the rest of those who quote the honey and beeswax market for the American Bee Journal. We want to get at the bottom of this matter, and if there is a better way to get at actual market values we desire to know it, and avail ourselves of it. What have the rest of the dealers to say?

GLEANING OF THE WEEK.—Mr. Tucker's son.—The picture on page 434 was taken from the roof of the barn. "The aged lady to the right is Mr. Tucker's mother, and next are his wife and daughter Grace. The young man on the left is his son, and the people in the background are his next-door neighbors. The little boys came in at the eleventh hour, but one can see them by looking closely.

It will be noticed that quite a few of his hives are covers, and he has not put on the lids of his hives. His two gable ends proper are made out of 4x4s, of an inch thick, for the under lid to lie in, leaving 1/4 inch to hook over the end of the hive. The center gable is an inch thick. The top lid projects one inch all the way around, and the tin is turned down over it. There are several layers of thin paper, 1/2 of an inch under the tin. The one-inch air-space and the paper make the cover all right, and it doesn't cost much more than the other kind.

Quoting the Honey Market.—Messrs. Blaie, Scott & Lee, of Boston, write us as follows in response to Mr. Cooley's letter on page 363:

American Bee Journal.—We note with interest the letter of Mr. Stoughton Cooley in the issue of Sept. 5, and as we have had the honor of quoting in the American Bee Journal for several years past, a word from us might not be amiss at this time.

Our method has been invariably to quote from actual sales. During the summer months—the period from May 1 to Sept.—the demand for honey, so far as we could judge that quotations are practically nominal, and although we received quotation cards regularly, yet during this interval, we very frequeently simply state that "the market is without change.

Now the question would seem to arise, Which is the more reliable, quotations given by the commission men from actual sales, or quotations from a trade paper? When it is known that the trade papers in the various centers must depend upon the commission men themselves for quotations, men who are largely engaged in making up the honey, melt the wax which remains; then when they have built their combs nearly down, set them out to be emptied and melted.

I think the improved condition of my bees in the beginning of the next harvest will abut pay for the extra labor; but until it has been tried, no one knows how it will work.
CONVENTION PROCEEDINGS

(Continued from page 660.)

REPORT OF THE TEXAS BEE-KEEPERS' CONVENTION.

BY LOUIS SCHOLL, SEC.

FIRST DAY—AFTERNOON SESSION.

The convention was again called to order by Pres. Sal-ley, at 2:00 p.m., and the first business was the report of the committee on constitution and by-laws. Secretary Scholl read the following, which was unanimously adopted.

CONSTITUTION.

ARTICLE I.—NAME.

This organization shall be known as "The Texas Bee-Keepers' Association."

ARTICLE II.—OBJECTS.

Its objects shall be to promote the interests of bee-keepers; the exchange of thoughts, experiments, etc., in apiculture, through the meetings of this Association; and through a closer relation of its members.

ARTICLE III.—MEMBERSHIP.

SEC. 1. Any white person who is in accord with the objects and the aims of this Association, may become a member upon the payment of $1.00 to the Secretary-Treasurer, payment to be made at or before each annual meeting of the Association; or not later than 10 days thereafter. Membership will continue as long as all dues are paid up.

SEC. 2. Any person may become an honorary member of this Association upon a two-thirds vote of the members present.

ARTICLE IV.—OFFICERS.

SEC. 1. The officers of this Association shall be a President, a Vice-President, and a Secretary who shall be ex-officio Treasurer.

SEC. 2. The officers shall all be elected annually by ballot of the members of this Association at their annual meeting.

ARTICLE V.—DUTIES OF OFFICERS.

SEC. 1. President.—It shall be the duty of the President to preside at the annual meetings of this Association, and to perform such other duties as may be devolved upon him by the Secretary-Treasurer. The President shall be ex-officio Vice-President of the "Texas Farmers' Congress."

SEC. 2. Vice-President.—In the absence of the President, the Vice-President shall perform the duties of President.

SEC. 3. Secretary.—It shall be the duty of the Secretary to keep the records of this Association; to make a report of the annual meetings; to receive membership fees; to make a report at the annual meetings; and perform such other service as the Association may direct.

SEC. 4. The President, Vice-President and Secretary shall form an Executive Committee. Their duties shall be such as usually fall to such officers.

ARTICLE VI.—FUNDS.

SEC. 1. The Secretary shall remit to the General Manager of the National Bee-Keepers' Association, within two weeks after the annual meeting, the sum of 50 cents for each paid-up member, as a membership in the National Bee-Keepers' Association for one year.

SEC. 2. The Secretary shall receive not less than $1.00 annually for his services, and shall receive another sum equal to his legitimate expenses for the benefit of this Association.

SEC. 3. The remaining funds of this Association shall be expended as the members thereof may direct.

ARTICLE VII.—MEETINGS.

This Association shall hold annual meetings at such time and place as the members may select by a two-thirds vote at some regular meeting; but if in any event it becomes impracticable to meet at the place selected, because of unforeseen events, then this Association shall hold its meeting at such time and place as the Executive Committee may select.

ARTICLE VIII.—COMMITTEES.

The President of this Association shall appoint, yearly, the following committees: Resolutions and Petitions; a Program Committee of one; and such other committees as may become necessary.

ARTICLE IX.—GENERAL.

SEC. 1. This Association shall ally itself with the Texas Farmers' Congress in every way possible, provided that such alliance is never detrimental to this Association.

SEC. 2. It shall be one of the aims of this Association to secure the passage of a law establishing an "Experimental Apiary" at College Station, together with the appointment by the Governor of an expert apiculturist, who shall be recommended to him by the Texas Bee-Keepers' Association.

ARTICLE X.—AMENDMENTS.

This Constitution may be amended by a two-thirds vote of the members present at some regular meeting.

The new association now bears the name of "Texas Bee-Keepers' Association," leaving the "North Texas" and "South Texas" associations as "local" bee-keepers' associations. Every Texas bee-keeper ought to be a member of the Texas Bee-Keepers' Association now, as with its new constitution and a new set of officers a great deal of good work can be done if the bee-keepers will only realize that which these men have asked for—the help, assistance and co-operation of the bee-keepers, and with that the Association could make strides forward as never before; only we need to work to help our neighbors, every bee-keeper ought to take pride in helping to build up a State association that will surpass all others, and this can only be done if they will give their assistance. Put your shoulders to the wheel, that is, your dollars into the treasury, paid for your annual membership, and help to keep it going. The greater the association, the more members it has, the more can be done.

Now something about what you get if you want to be a member:

By paying your annual dues of $1.00, you are not only a member of the Texas Bee-Keepers' Association, but 50 cents of this one dollar is sent with all of the other members, to the general manager of the National Bee-Keepers' Association, securing membership with that organization also. Thus one is a member of his State association, and at the same time can enjoy all the benefits of the National Association at just half the regular rate. Of course, it will be well to bear in mind that to do this, members must act according to Article III of the Constitution of this Association, in regard to membership and membership fees.

Besides all this, a reduction has been secured in the subscription prices of our bee-papers, when pay for them is given to the members of this Association along with their annual membership dues.

The Secretary was instructed to write to each member, of the change that has taken place; of the new name of the association; of its new constitution; its new business, objects and intentions; and to notify them of their annual dues of one dollar.

After this the general subjects on the program were again resumed, namely: "Manipulating Bees for a Large Yield of Extracted Honey," by O. P. Hyde, who said the main objects were, to have good, prolific young queens; large hives, not less than ten frames, then tier up as soon as room is needed, three or four stories high, and as soon as filled and well capped over take out the honey. He also touched on the minor points connected with producing large amounts of extracted honey; the above being the main objects.

W. O. Victor read an article he contributed to the Review, which, however, is too lengthy to copy, and the issue is not before me to make a summary.

FORCING QUEENS TO LAY IN CELL-CUPS.

"How Can Queens be Forced to Lay in Queen-Cell Cups?" was answered in a paper by H. H. Hyde. He does not claim to be responsible for being assigned that subject, and hopes nobody will be disappointed if he fails to give satisfactory solution of the question. He has not much experience to prove or disprove this query, but cited a case where he put cell-cups in top-stories of good colonies before grafting, to have them polished by the bees; when he distinctly remembers where in one case the queen laid an egg in such a cell, which was built out and hatched a queen. He said further that by placing cell-cups conveniently in a hive of bees that wish to supersede their queen, such queens could be forced to lay in them. Also at swarm-
ing time, queens can be forced to lay in such cell-cups conveniently placed in the hive; at other times it would not seem to be advisable, and can only be done with difficulty.

Mr. Stachelhausen thinks that it can only be done during swarming-time.

Mr. Atchley told how it could possibly be done, by placing a queen on their drone-board, and where queens are mostly found after their regular season's laying has been at its fullest, when the queens are almost worn out from the hard work of depositing worker-eggs. It is then that they are almost crazy to resort to delectable food. From this it seems that we could do this than that of laying worker-eggs. This is of course, the other cases cited, will be at about swarming-time.

**IMPORTANCE OF GOOD QUEENS.**

A paper from Willie Atchley on this subject was read, in which he said that too much could not be said about queens. Good queens, good bee-keepers, and good localities make bee-keeping a success; and either of these essential characteristics is treacherous when the other is wanting. For this purpose it is extraor-
dinary to see that all apiarists look sharp to the propitiousness of their queens, and the working qualities of their bees. Give him good queens, and a good location, and he will turn out a crop of honey.

Mr. Weaver and others gave some of their experience about good queens, a good locality, good queens, and good management, being a sure road to success. Some told about the difference in queens, some being large and fine looking, but of little use. Others have the abilities of the very smallest, sometimes called "stub" queens, have done wonders. This, however, is not a rule.

**BEARING GOOD QUEENS.**

This was by Mr. G. F. Davison, who gave his modus operandi, which were given at previous meetings of the Central Texas Bee-Keepers' Association.

He recommends the Alley plan he has so long practiced, and with which he has been successful. He lays in favor of the Doolittle plan and method, and although the best queens can be reared by the Alley plan, with the Doolittle method good queens, and more of them, can be obtained.

**MOVING BEES.**

O. P. Hyde has much and varied experience in moving bees, as he moves bees nearly all the time. He has also had some fun connected therewith, on which account he began to study how to find out the best way to move bees, and has been quite successful. To close the entrances, he uses a device (the idea of which he obtained from a bee-keeper who did not know anything about bees, only having a colony or two), which he can close up the entrances of 10 hives in one closed to the ordinary way, by tackling wire-cloth over the entrances. It is simply a piece of tin about two inches wide, with a cleat or piece of board half as wide nailed on the side, to which the wire is fastened. The lower half of the tin is perforated to give ventilation. Now with two 3½ wire nails in the cleat, just tack on the entrances, and it is done.

Next, the cover is nailed down with two more nails, one on each side, into the side-walls of the hive. Two or more story hives are held together by means of strips of lath nailed to the sides of the hive, diagonally across the sides.

In hauling, one should have a wagon-bed wide enough so two hives can be set end to end across the bed, and other time it is most wonderful in regard to the quick growth of honey-yielding and other plants after a heavy rain, the flowers appear most abundantly in a very short time. It is then that they move whole apiaries from dry situations to the fields yielding more. For all this they have wire-wagons, and some 200 regular shipping-

cases with wire-cloth, provided with slotted cleats in which the frames are hung, with all the bees put in, closed up, and the two sides of the box then riveted together. The empty hives are hauled on any other wagon separate from the bees.

Mr. Victor makes large frames by ripping hive-bodies into one piece, and much wire cloth is turned over.

This is nailed over the top of the hives after the covers have been removed. He next sticks moss into the entrances, nails cleats, one on each side of the hive, and they are ready.

H. H. Hyde recommends cleats nailed on diagonally across the entrances, and from their being done, they are recommended to develop the colonies at the right time.

Mr. and other bee-keepers' experience has taught that in their localities they can get their colonies developed to the most possible strength before the main honey-flow commences, for which purpose it is necessary to use different methods in different localities. In most localities this honey-flow is so early that we have to do all we possibly can to develop the colonies at the right time.

**IMPORTANCE OF LARGE BREEDING-SPACE.**

In a paper on this subject L. Stachelhausen said the secret of successful bee-keeping is to have the colonies at their fullest development just when the main honey-flow commences, for which purpose it is necessary to use different methods in different localities. In most localities this honey-flow is so early that we have to do all we possibly can to develop the colonies at the right time.

Mr. and other bee-keepers' experience has taught that in their localities they can get their colonies developed to the most possible strength before the main honey-flow commences. In this way, the beehives can be cut down, and the combs used for the first time in the colonies. For this reason, the bees have to be watched closely all during spring, causing a considerable amount of work, limiting the number of colonies that can keep, especially if scattered in different apiaries.

If in large brood-chambers, with a large amount of comb-surface, all this work is unnecessary, because the development of the colony is carried on, showing at once the advantage of such large brood-chambers. More colonies can be kept with the same amount of work; and even if the honey crop per colony should be smaller, which is doubtful, as by other management, the profit of the whole apiary will be larger. To get strong colonies in the spring, in such hives, it is necessary always to have enough honey in the hive, but not too much, with sufficient number of empty cells, or always enough more than the bees need at a given time.

Another advantage of large brood-chambers is that swarming is reduced to a minimum, especially so if the bees are kept in large hives during several generations. In this way the concentration of the colonies is great, so much so that in certain localities swarming can be practically prevented by the use of large hives, while in other localities the number of swarms is reduced very much, and, to prevent these few swarms, other ways can easily be executed.

Nobody disputes these advantages of large brood-chambers in early spring, but some say that they have disadvantages during the main honey-flow. It would seem to be a question worth asking. Why should the bees be prevented as long as they are advantageous, and afterwards contract the brood-nest as soon as possible? But this objection can not be overcome by this simple way.

1st. One objection is, when producing extracted honey, and having an extensive field of work, the flow of honey, the brood-nest will be contracted by the honey which the bees store around the brood. Contrary, in a moderate honey-flow, it is said, that the bees will use the large space extensively, and will store very much honey at the end of the flow leaving a strong colony of useless

Bee-Diseases in California—Laws Needed.

By HON. J. M. HAMBEUGH.

A LL is not gold that glitters, but every cloud has its silver lining. This is more especially true of our chosen pursuit of bee-keeping here in California, and among the many clouds that hang about the bee-keepers’ horizon is that of bee-diseases.

Here, in this salubrious clime, where every month in the year, and almost every day in the year, bees are on the wing in quest of pollen and nectar, opens opportunity for the spread of infectious diseases, and this, coupled with the wild waste of rocky cliffs, canyons, and wooded districts, furnishes hiding-places for bees, that can wreak and fester in diseases un molested. It is hard for the wide-awake bee-keeper to overcome these dangers beyond his reach, but there is a danger of far greater magnitude right at his very door, that he needs to recognize, and which needs a cure, in the shape of a little more insistent legislation.

Here is Mr. A., a practical bee-keeper, with all his combns throughout his entire apiary movable and accessible at any time for inspection, and in appropriate condition to battle against any disease that may arise. Mr. B., his next door neighbor, is of the slipshod, go as you please school, has combns in the brood-chamber, and the consequence is, he is locking the door against all knowledge or treatments for comb diseases, both internal and external, and is also in shape to be (as it were) hugging an adder to receive its fatal sting, and also to dispense its venom among his neighbors. When there is such a deadly foe as foul brood abroad in the land, these inaccessible hives are a veritable death-trap, and, so far as inspectors are concerned, they are simply barren from investigation, save what the exterior may reveal.

In our route through the country these troubles are so manifest, and there is such a universal cry against their persistence, that it seems to me a very easy matter to have a law placed upon our statutes, compelling every one who keeps bees to have them upon movable combns, built in movable frames, and, by so doing, minimize the chances for comb diseases, and if not drive them entirely out of the soil, also in shape to be (as it were) hugging an adder to receive its fatal sting, and also to dispense its venom among his neighbors. When there is such a deadly foe as foul brood abroad in the land, these inaccessible hives are a veritable death-trap, and, so far as inspectors are concerned, they are simply barren from investigation, save what the exterior may reveal.

We also believe that a little further protection is needed to the bee-keeper, by statute enactment, and that is, when a bee-keeper contemplates moving from one location to another, he should have a certificate from a lawfully appointed inspector, the said certificate to be an assurance that each and every colony is free from all infectious or contagious disease, otherwise let it be a final offense to remove them from their old location.

Now, Editor York, I have sounded the warning bell, and if others interested, and see which one of the sister States will be the first to start this good and much-needed reform.

Robbing in the Apiary—Honey-Packages.

By C. DAVENPORT.

I WOULD like to be allowed to say a few more words in regard to robbing. Last year I wrote an article in which I gave some of my experience in regard to bees robbing, and afterwards in some comments that were made about it, it was said, in effect, that the advice I gave on the subject was given without a hinting at those who were using the honey under such conditions as to scatter live coals among dry straw. But this is a mistake, for I did not advise any one to practice my methods; in fact, I remember that I plainly said that I did not advise any one to follow my practices. I only gave my experience in regard to the matter; but what I wish to say is that, in my opinion, it
will some time be known, and generally recognized by bee-keepers, that a colony of bees of average strength (and, I feel sure, without exception, quite weak colonies if in normal condition) are never, as the saying is, “cleaned out by the robbers,” or never molested by them enough to injure them materially in any way, no matter what has been done to induce robbing, or what the natural provocation to the same may be, excepting the usual raids by the robbers.

I have watched this matter very closely the last ten years, and, besides, from two different incidents I have witnessed, I know that a colony of average strength will, before succumbing to robbers, make such a fight as few would have imagined. Generally in these incidents may be of enough interest for me to take space to describe briefly.

It occurred in an out yard during a time of great scarcity. Some of the bees had long been starved, and the colony was being robbed; after much fighting, the robbers were defeated, though not without loss. I have never been able to get any kind of a barrel that would hold honey in a warm, dry room without leaking. Even when I coated the inside a quarter of an inch thick with wax or paraffine it would not prevent them from the allowing the honey to ooze out between the staves. My failure in this line was not because these barrels were not dry enough; I have kept both those made from hard and soft wood in a dry, warm room for two years, and then after driving the hoops as tight as could possibly be done, they would soon commence to leak after honey was put in them. I have not only tried different kinds, but a year ago last fall I had three large ones made to order, which were warranted not to leak.

We have, however, made what might be called success of sucking up evaporated honey from the same as old wheat or other grain. Last fall at one time I had about 1000 pounds sucked up. Possibly in the future extracted honey may be shipped in sacks instead of cans or barrels.

The way I came to put honey in sacks was this: The three empty barrels mentioned, which held about 500 pounds each, got to leaking soon after being filled—two of them badly. I had nothing on hand to put much of the honey into, but I had observed when using the no-drip shipping cases that if a section become broken or the wax honey ran down on the manilla paper tray in the bottom of the case, this paper seemed to hold it as well as a tin tray would; and I noticed, at the place where I board, a number of empty flour sacks which had been purchased. I found they had a large number of these flour sacks in the accumulation of years. The paper they were made of was very much heavier and tougher than that used in shipping cases, and, being glazed or smooth like the latter, it was slightly rough or porous looking. I took a couple of these sacks and thoroughly coated the insides with beeswax, and filled them with honey. They held it all right, and soon afterwards enough sacks were waxed to hold the three hundred and ninety-five pounds contained.

The honey remained in some of the sacks nearly a month, and no leakage whatever occurred, except with one sack, and this was owing to a defect in the sack.

My method of waxing the inside was to pour a large quantity of melted wax in a sack, then with one hand gather up the points of the sack, and with the other hand take hold of the bottom at one corner, so as to turn it bottom side up and around in such a way that the wax would reach and coat all parts of the inside. This had to be done quickly, or a good deal of wax would adhere to a sack. It took considerable to wax them, anyway, but the honey was taken out, the sacks were cut up and boiled in water, by this means getting all the wax back again.

My success with these large sacks led me later to try small sacks for the retail trade. A good many who come to the house for a few pounds of honey never bring anything to put it in; few of them will buy a pail or jar, and if I lend them a dish to carry it in all of them will readily agree to return it and thus never do give. I have many customers in town to whom I carry a few pounds of extracted honey, and in this case I either have to wait for them to empty the dish I carry in, or else call for it again; when, if there is any one at home, we may perhaps find it has been filled with something else. For instance, last season one lady ordered three pounds; I had nothing smaller than a gallon jar on hand, so I delivered it in that. When I called for the jar, some time afterward, it was full of butter. She said she had forgotten I had lent her a honey jar.

So far as I could determine, the results of this experiment last season lead me to believe that I can reach this class of customers with a package that will go with the honey, for it will cost only about half a cent aside from some service in preparing it, which can be done during the leisure time in winter: a package that will give satisfaction to the customer, and be practically as safe to carry or deliver the honey in as one made of tin.

Southern Minnesota.

The Season of 1901, Suggestions, Etc.

BY A. BOOKE.

As the American Bee Journal is anxious to have reports from Bee-keepers, as well as any suggestions they may be able to make as a result of experience in the management of bees, I send my report of the season, as well as one or two suggestions that may be of use to beginners.

No Harm in Reporting Large Honey Crops.

My honey crop has been a very good one, but if I tell what it is, down may go the honey market. Pshaw, all rot! About the close of the season, which has been a fairly good one for me, I received some suggestions from the papers, made some enquiries for use in the weekly report. A statement was given which appeared in the next week’s issue, that Mr. So-and-So’s honey crop would likely be 5000 pounds, from some other colony. But in the next report in the paper appeared, the demand for my honey has been so great that I could sell ten times the quantity I have, and at better prices than I have formerly realized. Since the said report was given, I have been about finishing extracting, and find the quantity to be fully 10,000 pounds, and I am pleased to find that most of the colonies have a fair supply for winter, so that very little feeding will have to be done. A considerable number of the colonies, I find, are but superseding.

Having all the bees I was able to take care of, and had room for, I discouraged swarming, and have only an increase of about 25 percent. I have not practiced queen-clipping, but, having no help this year, I was unable to do so. I so close a watch upon them as is necessary when the queen’s wings are not clipped, and as a result I lost several swarms.

Next season I will try what clipping will do to prevent this.

Building Up Weak Colonies.

I notice that several correspondents are troubled to know how to build up weak colonies in the spring, or, in fact, at any time of the year. I have practiced changing positions of the wax with the colonies for many years, with very good results. I suggest doing this on a fine day, when the bees are either gathering pollen or honey—say about noon—and if I have a colony becoming very strong, and I do not want increases when returning the bees to the colony in the way suggested, and the chances are that swarming may be averted, and your colonies all averaged up and ready for the honey harvest.

I have a very weak late swarm of nice bees, that I wanted to retain, but they were entirely too weak to build up. I changed positions with a strong colony a few days before the honey-flow ceased, with the most satisfactory results—no fighting, nor any disturbance that I could notice.

Cross Bees—the “Joucing” Method.

My bees were unusually cross this year, there being only a day or two at the close of the basswood flow that I could extract without a veil, and mostly had to use gloves in addition to being well protected. I have tried the “joucing” method of getting the bees off.
The frames, recommended by Mr. Davenport, but while it may work with nearly empty frames, or the shallow Heddon frame, I am satisfied it will not do with any large-sized, well-filled frames.

**NO USE FOR BEE-ESCAPES.**

I have also tried bee-escapes, but have given them up as practically worthless. I have no time to fool away with them.

The honey-flow exceeding my expectations, I had to defer extracting for want of tins to put it in, and so tried bee-escapes, but, being alone, I found it about as much trouble, and got about as many stings getting the bee-escapes adjusted, as I did in getting out the combs without them. My plan was to start after noon, give the bees a good smoking, take out the frames quickly, and run them into the extracting room, and stack them up three and four deep, until I had 10 or 12 in; then extract these. In the meantime the bees would get somewhat quieted down in the yard, and I would then get off a few more. Any bees that would go in on the combs would soon find their way to the windows, and go out of the escapes.

The season being unusually dry, the honey is of very fine quality, and sells readily in small quantities at 10 cents. Latterly we have had abundant rains, and the bees are breeding freely, which augurs well for good wintering.

"HIVING TWO SWARMS IN ONE HIVE."

On page 581, Mr. Davenport says he has had no trouble from hiving two swarms together when both issue at or about the same time. In July last, when I had a large swarm nicely hived, but before I could remove it, a large swarm issued, and there being a cluster of bees on the front of this hive, it came down and went in with them. I at once put on a queen-excluder and two cases of sections with mostly drawn comb, to give them room. On the 5th day after, one of the swarms came completely away, and clustered on a limb of the tree exactly where the first swarm had clustered, which led me to believe that it was the first swarm that had left the hive, as the others never clustered at all. The time between the issuing of the two swarms at first was not more than 15 minutes.

My experience thus far leads me to conclude that bees do not do everything by rule, and we may always expect them to do something we never knew them to do before.

Ontario, Canada.

**The Afterthought.**

The "Old Reliable" seen through New and Unreliable Glasses.

*By E. E. HASTY,* Sta. B Rural, Toledo, O.

**THE TWO-HIVE FEEDING PLAN.**

Yes, Mr. Fargo's two-hive feeding seems to offer fine possibilities. But first we must find out whether it will work as a regular thing, or only in exceptional cases. If the open-topped screen-yard we had up a bit ago will work that will be pre-eminently the way to feed. Apparently the two ways will combine kindly. I think that one grand trouble about prolonged feeding in the home hive is that bees declare it annexed, and decide to let it be needed. So be the danger of the same thing in the two-hive method. In the open air a salutary fact that somebody else may get it will keep all but the very lastest pegging away. Page 531.

**BLACK COMBS DISCOLORING HONEY.**

I agree heartily that black combs will discolor the inclosed honey somewhat; yet I fear that the attempts to soak them clean are entirely unpractical. The situation is this: Many layers of dried dirt, separated by many exceedingly thin layers of silk or wax. The best we can do is to keep the whole thing dry. The first soaking removes part of an outer layer, and makes the whole wet and nasty. With each successive soaking more and always more will be coming "from away back." Ram a two-quart can one-fourth full of dirty ham-salad-nachos (such as are found in a bee-keeper's trouser's pocket at the end of a hot week); fasten them down so they can not be moved about; and how long ere the bottom layer will be cleaned by turning water in and out the top? Page 581.

**HIVING TWO SWARMS TOGETHER.**

To C. Davenport, page 584, I would say that my experience with voluntarily hiving two swarms together is not large, because I usually do it when I can; but they get together in spite of me pretty often; and my troubles with balled queens when swarms are mixed are by no means imaginary. Quite willing to let his many successes have their due weight — and also quite glad to have so sound a veteran to fall back upon as Dr. Gallup, page 582:

"If you have two or more swarms come out at one time and cluster together, or if you have after or second swarms with more queens than one and you wish to separate them, shake them into the clustering box and let them stay for half or three-quarters of an hour, and the bees will ball the surplus queens, and roll down to the lower edge of the box."

I note that Dr. Gallup says, "Sometimes they ball every queen, but not usually." I think that with me balling every queen is rather the rule than the exception, if the swarm is a mixed one. Why this difference? His experience, I think, has been mostly in fat locations, where bees seldom swarm except during honey-flow. My experience has been in a lean location, where bees often swarm in time of dearth. As I see things, bees carrying little or no honey are not sure to be cross to their 'keeper, but pretty sure to be severe on stranger queens. In a mixed swarm all the queens are stranger queens to thousands of the workers, and if they balled some of them, and did not ball all of them, it would be a curious fact calling for explanation.

I listened to see that Dr. Gallup has had experience in making a colony into an impromptu swarm clustered in a box for the purpose of moving their location a short distance. Have wondered whether that would work. He finds that it does.

**HARD TO DESTROY ALL DRONE-BROOD.**

I smiled when J. D. Gehring said that he found destroying all drone-brood harder than he expected, and that unforeseen things happened. Been there. My wife is frequently heard to say, don't you be too sure you can destroy all drone-brood — not even by the excellent Doolittle plans on opposite page. Page 583.

**SHOWING MERCY TOWARD ANIMALS.**

Prof. Cook, on page 567, did not pass on from mercy toward animals to mercy toward bees; but there is room for quite a sermon on that point. This paper surely goes to many readers who want to do just right in the little things of life. I have often felt it a difficult problem to decide just when a bees' little life ought to be spared (at appreciable expense of time, which means money), and just when the prompt sacrificing of the little life is the real right thing to do. I have also wondered about the would-be rookers and stingers, how much less claim they have upon our mercy than the unseen insect men of the hive. I rather think that the insect door-keeper, doing duty promptly and well, should be a subject of admiration to a reflective and right-minded man — and that the sentence, "If stung me," ought not to be in such large vocal type as it is often put. Per contra, there gets allotted at times a considerable amount of sentimental nonsense and unwisdom, which would faint make us more careful of insect life than the Creator is himself, and which would make apiculture impossible before we got to its logical conclusions.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of $1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free — if you will mention it.
**The Home Circle.**

Conducted by Prof. A. J. Cook, Claremont, Calif.

OUR VENICE.

Time and money spent in welding all the home influences and attractions and loves and sympathies, are well spent. A year ago I was driven along the “Mountain Boulevard” which leads from Santa Barbara to charming Montecito. This drive of nine or ten miles is one of exceeding beauty, it seems to me of incomparable beauty. As we sped along looking now upon the beautiful ocean, now skirting some beetling cliff, now plunging into some bower of green that seemed to blot out all else for a moment, I heard over, “Oh, that the others of the home were here!” I said, “Before a year goes by, they shall, with me, enjoy this bit of Nature’s finest tracery.”

The year has been a brighter, happier, better one, as the memory of the charming landscape has given added charm to my life, and as the prospect of all of us of our home circle making that beautiful circuit together has been ever before me, I have been in a sort of perpetual sight seeing with the desire to see it all through the year through. But the far summit of this pleasurable experience was only reached when last Saturday we all actually enjoyed together that wonderful bit of landscape. It was a red letter day in our family.

Santa Barbara has been called the Venice of America. We have never looked upon Italian landscape, but to me it suffers from no wrong in the figure. While there is not the thrill and wondrous beauty in its entirety that we so much prize and admire in Redlands, yet here one of the finest hues of the world’s incomparable charm is before us. Many beautiful homes attract us as no other section of California can or does. I have never seen such a wealth of adornment in shrubs, trees and flowers, as this section has to offer. As I come home from each year—and I never pass them by—I feel that I have a real ownership in them. The graceful eucalyptus, the incomparable bamboo, the delicate exotic tree-ferns, and countless other vines, shrubs and trees, fill one with delight and admiration.

Montecito, the wonderful suburb, has some of the finest homes and the best adored residences to be seen anywhere. As one drives along among the hills, shaded by live-oaks, he is ever and anon coming to a place where wealth, taste and Nature have combined in the most incomparable charm before us. Many beautiful homes attract us as no other section of California can or does. I have never seen such a wealth of adornment in shrubs, trees and flowers, as this section has to offer. As I come home from each year—and I never pass them by—I feel that I have a real ownership in them. The graceful eucalyptus, the incomparable bamboo, the delicate exotic tree-ferns, and countless other vines, shrubs and trees, fill one with delight and admiration.

As I come home from each year—and I never pass them by—I feel that I have a real ownership in them. The graceful eucalyptus, the incomparable bamboo, the delicate exotic tree-ferns, and countless other vines, shrubs and trees, fill one with delight and admiration.

The ANTI-LION.

A queer insect! What strong, sharp jaws! What a fierce, daring temper! A very rat-terrier among its kind. A unique home is his. He always dwells in the loose, shining sand. Above him is only space, for he rests at the very bottom of a funnel in the friable earth. His threatening jaws are alone visible; for all else is covered by the sand. Above him the side walls of his funnel are so steep that even the quick, wary ant passes its margin at its peril. Once our eager, daring, fearless ant-lion feels the tell-tale, falling sand, and he knows that another victim has had the temerity to brave the lion in his lair. He at once throws a harsh shower of sand, which surely brings the intruder down to the very jaws of death. No sooner has he the luckless wanderer in his merciless jaws than the latter is shaken as never a rat-terrier shakes his prey, until the poor victim has daylight and life shaken from him. Thus these ant-lions are our good friends, for they take their own meals from insects that would else feed on our fruit.

Shepherd’s begonias, they are in the not distant garden of her neighbor, Mrs. Gould. The whole world is enriched by the fond efforts of these two women. We have rarer, richest beauty that else we should not have known, for they would not have been.

Again, two women have done this beneficent work. We expect new, rich, rare developments from men. We have not usually found our grand women stepping to the front in such realms. We glory all the more when such strides are taken. I wish every home in the land could enjoy Mrs. Shepherd’s begonias, and every household know more of God and pleasure because Mrs. Gould’s petaunias were daily companions. I know of one home that is so blessed, and its inmates are very grateful.

HOME FLOWERS.

I know of an orange orchard, ten acres, which recently sold for $12,000. I thought it a great price, and so asked the recent owner how he was so fortunate in his sale. He replied: “My roses and palms did it.” His entire place is skirted by great fountains of green in the magnificent Phoenix palms, and alternating with these are most lovely roses, which grow and bloom as only California roses can do. Why can not every home rejoice in such loveliness?

I know that next to wife and the dear children, nothing so weds us to home as the flowers. I heard a lecturer say, a day or two since, that it was his business a few years ago to visit all the homes of a certain region. He said he found the home yard and porch the most certain index to the refinement and courtesy that would greet him in the home. He said he fancied that even the dogs in the flower-placed homes were more kindly in their reception. I believe it. Flowers beget a kindly, genial spirit, and every dog even is quick to feel and sure to be mellowed by such spirit. Were the flowers to be taken from our house, porch and yard, we would all wish to go with them.
Questions on Breeding of Bees.

1. In selecting queen and drone mothers, what is the most important part to look to, to improve the stock?

2. Why do the most of queens produce drones not uniformly marked? And some queens will produce uniformly marked drones. Does it denote impurity with those that do not produce uniformly marked drones?

3. Do you think it best to have the queen mother and the drone mother of no kin? or does it make any difference if they are closely related?

4. Are there queens from a queen that is mislaid, but reared from a pure mother?

South Carolina.

Answers.—1. In either case the important thing for practical purposes is to have mothers whose worker progeny show good results in the harvests gathered. All the better if of pure-established blood, but in any case the workers should be good honey-gatherers.

2. I don’t know why. I hardly think that a difference in the appearance of drones is a sure proof of impurity.

3. Other things being equal, it is decidedly better that there should be no relations, but improvements and advanced strains make some of their greatest triumphs through using closely related blood, because it is easier to find the same characteristics in two animals nearly related; but while it is easier to perpetuate good qualities through close relationship, it is also easier—perhaps I ought to say, it is still easier—to perpetuate bad qualities through close relationships. On the whole, I believe it is a pretty safe thing for bee-keepers like you and me to let close brothers alone.

4. If I should be obliged to answer that question in a single word, I should say yes, and for all practical purposes that is the right answer. But if you draw the matter very fine, it will be true that when a drone is the offspring of her own blood may to a slight degree be affected by the blood of her offspring, and hence the drone offspring may be slightly affected. Dzierzon, however, always counted that the mating of the queen had no effect upon her male offspring.

Several Queen Questions.

1. I have been working a few colonies of bees for six years. I now have 30 colonies, and this season I have been more successful than ever. After all their actions. In the place, my text books and papers teach me that with the sealing of the first queen-cell the old queen will issue with a swarm; but I have had several instances this summer where it failed to be true, after watching them for several days, after the cells were sealed, for swarms. I either killed or caged the old queen and destroyed all but one cell. What was the cause of their acting so? Was it a case of intended supersede? If so, how am I to tell which is intended to swarm or supersede?

2. The queen of one of my best colonies disappeared, and they swarmed with a very small virgin queen. My wife caught her, but she got away and the swarm returned to the old hive, 3 days after. At 5 o’clock p.m. this morning I looked through the colony and found a very fine virgin queen, and several capped cells, so I closed the hive and watched for a swarm. The queen kept peeping off and on, all day, but no swarm issued, and after watching for two days I opened the hive again and found the fine queen gone, and a small one in her place, and cells all destroyed. What was the cause?

3. I had several colonies in normal condition, that sealed queen-cells without anything in them; or, at least, after waiting beyond the required time I opened them and found them empty.

I received a premium queen and tried to follow directions carefully, but after eating the pasteboard off and part of the candy, they quit and kept clustered very tightly over the cage. After waiting three days I smoked them and turned the queen loose, but they balled her immediately. If re-caged the queen with them and put in a spot where there is a brood and女王strength, put over a strong colony, with a flour-sack between, for several days. I kept her caged with her attendants for a day, then turned her loose, and after two or three days set the hive on a stand by itself, and opened the entrance; but the next time I opened the hive she was gone. Now, what became of her? She acted like a virgin.

Nebraska.

Answers.—1. "Bees do nothing invariably," and there are exceptions to all rules. It is impossible to say whether queen-cells are intended for swarming or superseding by the appearance of the cells, but you can generally make a pretty good guess from attendant circumstances. If you find only two or three cells, you are pretty safe in guessing that swarming is not intended. If the cells are advanced, or the first begun for swarming there may be only one or two. If 8, 10, or more cells are started, you may feel pretty sure that swarming is in contemplation. The time when cells are found will help you to form a guess. Early in October the bees are issuing every day or so, the presence of queen-cells points pretty strongly toward swarming; when the honey-flow is about over, they point toward supersede.

2. A little hard to say. It is just possible that the small queen you saw was one that you had previously seen; sometimes a queen just out of the cell looks quite different in size and color from what she does later. But it may be that the bees concluded not to swarm, and allowed all the queens to emerge, or to be destroyed. The piping of a queen is usually an indication of a forthcoming swarm, but not always. To be a reliable indication of a swarm, there must be the piping of the free queen and the quaking of the young queen or queens still in the cell. Young queens quaking the day before or out of a cell in the hive, and a young queen may quark before emerging without the piping of another queen.

3. Are you sure that nothing had been in the cells? It is a common thing for bees to fasten the cap on again after the young queen has emerged, and sometimes they play a practical joke on a worker that happens to be in a cell from which a virgin has emerged, by fastening the worker in the cell.

It is possible that in some way the colony had a virgin queen—one might fly into the hive without your knowledge, or a queen-cell may have escaped detection—and so there was an unconquerable hostility to the stranger, which would be in a less favorable condition for acceptance through the journey in the mail and the propolis post office. Such a queen may look very like a virgin, and then after commencing to lay become as large as she was before maling. The probability is that the bees killed and dragged her out.

Dividing Colonies in Double Hives.

I have three double colonies. Would you recommend giving the top chambers a queen, and putting it where the bottom number is? Or simply placing the bottom and new stand? Or what is your plan?

Indiana.

Answer.—In this case the supposition is that a colony in two stories is sufficiently strong to be divided. As to the best procedure, conditions must be consulted. The plan you suggest is all right if the upper story is weaker in brood and bees than the lower story, or if the stronger of the two stories, giving it the new queen, putting the stronger story with the old queen on the new stand. If the desire be to have the two colonies more nearly equal in strength a story or two early in the season, when swarming is possible, you might make the division at a time of day when most of the bees were in the hive, and put the stronger half on the new stand with the old queen, fastening the bees in the removed hive for a time, perhaps till the middle of the next forenoon, and carefully guarding against accident. Of course the new queen must be caged as a newly introduced queen. But it’s pretty late in the season to talk about dividing now.
REVERSIBLE WALL MAP
OF THE
UNITED STATES AND WORLD,
WITH SPECIAL INSET MAPS OF
China, Cuba, Porto Rico, The Philippines, Hawaii, and Alaska,
Especially prepared to meet the demand for a first-class map that will give a quick, general idea of location of events the world over, and particularly to the United States and our territorial possessions. Very useful in every Home and Office.

a salient feature of this map not appro-
ached by any similar publication.

It has been pronounced a

Photograph of the World

The 1900 Census

of the largest American Cities is given.

One side shows a grand map of our great country, with counties, railroads, towns, rivers, etc., correctly located. The other side shows an equally good map of the world. Statistics on the population, cities, capitals, rivers, mountains, products, business, etc., a veritable photo-

graph of the UNITED STATES AND WORLD.

The map printed on heavy map paper and is mounted on sticks ready to hang. Edges are bound with tape.

1901 EDITION. Every reader should consult it every day. The plates show all the new railroad lines and exten-
sions, county changes, etc. Especial attention is given to the topography of the country; all the principal rivers and lakes, mountain ranges and peaks are plainly indicated. The leading cities and towns are shown, special attention being given to those along lines of railroads. The Canadian section of the map gives the provinces of Ontario, Manitoba, and British Columbia, with nearly all of Quebec and New Brunswick, the county divisions being clearly marked. The Southern portion of the map includes the Northern States of the Republic of Mexico, and the Ban-
a Islands.

On the reverse side is the Library Map of the World. The largest and most accurate map on Mercator's Projection ever produced. The political divisions are correctly defined and beautifully outlined in colors. The ocean currents are clearly shown and named. Ocean steamship lines with distances between important ports are given. A marginal index of letters and figures enables one easily to locate every country in the world. A series of short articles in alphabetical order is printed around the border of this map in large, clear type, containing valuable information concerning agricultural, mining, and manufacturing statistics, also the value of imports and exports in dollars. The area, population, form of government, and chief executive of every country in the world is given up to date, also the names of the capitals and their population. TheInset Maps are elegantly engraved and printed in colors. They are placed in convenient positions around the United States map, and will be invaluable to every person desiring a plain understanding of our possessions. An inset map of China on the World side of map adds to its value.

Two maps worth five dollars each, on one sheet, all for only $1.50, sent by mail or prepaid express; or we will forward it free as a premium for sending us Three New Subscribers at $1.00 each; or for $2.00 we will send the Map and the American Bee Journal for one year. Address,

GEORGE W. YORK & CO.,

A Good Yield of Honey.

I have a small apiary of 37 colonies, I started with two a few years ago. Some seasons they have done fairly well, and in other producing but a very little comb honey.

This has been the best season that we have had in the last section. The two years previous to this there were very light flows of honey, and during this time many beekeepers lost most of half of their hives, most of the loss being due to broods before being noticed the hive would be literally filled with large white larvae, that would consume the honey, and even the comb. But, as I said before, this has been a fairly good season in this respect and I have taken from one colony 346 pounds of nice section honey, well filled and capped; besides 10 pounds in sections that were filled and capped at a time of 350 pounds. I would like to ask if this is not the best record that you have ever heard of from one colony; although our colonies are much smaller than the California, the honey is winter, and the seasons longer, they may beat this.

—JOHN LENNET.

[Yours is certainly a good yield of honey, but we believe Mr. Doolittle once secured 560 pounds of comb honey from one colony in one season.—Editor.]

A Hive Roof and Shade.

Bees did well here until about July 1. July and August were so dry that they consumed a great deal more than they gathered during those two months. They gathered scarcely any pollen from the corn, which is generally a good pollen producer.

I will give a description of a roof for a beehive that I am using, and like it very much. Take hard, hard balsam that has been prospected, and put it in two or three pieces, and put them over the hive. I am not suggesting that the balsam will make the bees, but just to make them move in different directions. In use one at each end croswise of the hive to the other state or on down, making the bees crack, are nailed on a stake. It is light and handy, and will turn the rain as well as the sun. I have found this a lido or top for a hive, but a roof to turn the water and sun.

—HARRY S. HARBOLT.

Clark Co., Ind., Sept. 9.

"Making" Natural Swarms.

In answer to Mr. Hasy's "Not wise to hold the thing as an experiment until many have tried, others, and some have not." I have four swarms, knew of two or three going off, got one out of the rooks, so that I closed the season with 66 colonies; 6 or 4, however, have bee hives, and did good, either in honey or brood-rearing, for causes that are now remedied, but at the time I did not know what to do in the great cases. The rest were all very large, strong colonies, 2, 3 and 4 stories full of bees from top to bottom. Mr. Doolittle says: Varroa and artificial swarming, in Gleamings in Bee Culture, and I determined to try it on some of the small colonies, before the main flow was all over, and just about the time I made my last extracting the latter part of July, I used this Swa. It will not add all you say it will." Catalog and price-list free.

Barnes' Foot Power Machinery

Read what J. P. Parent of Charlotte, N. Y., says: "Wanted with best results my Farm Combed Machines, last winter, 100 acres, 250, 100 honey boxes, 500 brood, 60 frames, 300 sacks, and a great deal of other work. This winter we double these figures, everything was to make, and we expect to do twice as well. We will do all you say it will." Catalog and price-list free.

Golden Honey-Plant.
I send a honey-plant which I desire named. There is much of it growing here on the bottom lands, and it is the greatest honey-plant we have in this part of the country. The nectar flows in it for about one month. It grows about 4 to 6 feet high. The honey from it has a yellow cast.

Our bees did no good this year in storing surplus honey.

J. L. BADER.
Coffee Co., Kau, Sept. 20.

The plant in question is the famous Golden honey-plant—Actinomeris squarrosa—and belongs to the great Composite family. It grows tall and branching in rich, loamy soil, and is a boon to the apiarist. Prof. Cook, in the "Bee-Keeper's Guide," page 301, mentions the plant as possessing a great attraction for bees. Many other composite flowers are good honey-producers, such as the bonnet, aster, goldenrod, etc.—C. L. Walton.]

Honey-Dew on the Hickory Leaves.

EDITOR YORK—I send some shellbark hickory leaves for your inspection. They were plucked at 11 o'clock a.m., covered with honey-dew ( ). For weeks the hickory leaves have been covered mornings with this stuff, sometimes so thick it would run down and fall in big drops. The bees gather it industriously. Toward noon it dries up considerably, but I have some leaves on my desk that...

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Sept. 15.—No. 1 white honey is worth $1.50 per pound, with occasional lighter prices. Little more is being offered for fawry, which does not grade No. 1. Selling at from 1.00c to 1.60c; light amber, 55c to 70c; dark amber, 85c to 1.10c; and all grades of white; some fancy white clover and balsamwood bringing 3c. Honey from Ohio, ranging from 50c to 70c; dark at 55c. Beeswax firm at 280c.

R. A. BURNETT & CO.
CINCINNATI, Aug. 10.—The honey market is rather dull as of late. Honey is selling at from 1.00c to 1.50c, and Beeswax hogsheads from 1.35c to 1.50c.

C. W. WEBER.
BOSTON, Sept. 27.—We quote our market as follows: Fancy white in carons, 16c; No. 1, 15c; No. 1, 14c. Extracted, white, 95c; light amber, 8c; dark amber, 65c.

BLAKE, SCOTT & LEE.
ALABAMA, Sept. 19.—We quote: Fancy white, 16c; No. 1, 15c; No. 2, 15c; 4 lb. backwheat or amber, 12.5c. Extracted, white, 76c; light, 65c to 75c; dark, 50c. Beeswax, 26c to 28c.

OMAHA, Aug. 8.—New honey is arriving by express in small quantities from Iowa and Colorado, and selling at $1.50 per case in a return carton. California extracted honey is being offered carlots at 45c to 55c per pound, f.o.b. California. Shipping charges are paid on small lots of any sales having been made thus far. The production of extracted honey from the clover this year is large this year in Colorado, Utah and California.

PEYCKE BROS.
NEW YORK, Sept. 10.—Comn honey is now being brought to us for receipt at our warehouse, and is selling at 35c to 45c per pound, f.o.b. New York.

PEYCKE & CHANEY.
DETROIT, Aug. 12.—Fancy white honey, 15c; No. 1, 14c; No. 2, 14c. Extracted, white, 60c; Beeswax, 26c to 28c.

M. H. HUNT & SON.
BUFFALO, Aug. 16.—Quite a good demand for fancy honey, 15c; No. 1, 14c; No. 2, 13c. Fancy white, 11c; old neglected. Adverse moderate shipments only of new as yet.

BATTISON & CO.
SAN FRANCISCO, Sept. 4.—White comn, 10c to 12c; amber, 55c to 65c; dark, 65c to 70c. Extracted, white, 50c to 60c; light amber, 45c; dark amber, 60c. Beeswax, 320c to 350c.

Arrivals and spot offerings are of rather moderate volume, but there is much more on the way, and it is expected that it will all be vigorously placed. To secure liberal wholesale custom, prompt and reasonable prices are offered in favor of bayers. In a small way for especially desirable lots slightly higher figures than are quoted are realizing.

KANSAS CITY, Sept. 14.—Up to the present time only small lots of new honey comn have been received here, the market is rather quiet and will probably remain so until our own honey is available, which will be on the market at the rates heretofore quoted. Inquiries for comn are still coming in, and the firm market is anticipated. Inquiries for ex-

Available spot amounts are of rather moderate volume, but there is much more on the way, and it is expected that it will be vigorously placed. RED CLOVER QUEENS

BLACK ROCK, N. Y., Sept. 3, 1901.

FRIEND ERNEST,—I will try and tell you what you want to know about that queen. I get her from you in 1899 as a premium with GLEANINGS. I never saw a small colony of bees build up as that one did. In the spring of 1900 they came out in fine shape, wintered perfect. I raised them up in May and gave them 3 frames more so the queen would not want for room. I never saw such a colony of bees as they were in June, and they were actually storing honey when other bees in my yard were starting. No! they were not robbing. I never saw those two best colonies of mine trying to rob. THEY CERTAINLY WORK ON RED CLOVER. This is no guesswork, as I have seen them. As you know, the past two seasons have been very poor, and what honey my bees did get in 1900 candied soon after cold weather set in. I packed this colony in a chaff hive and left them out, thinking that such a strong colony would winter perfect. The snow came on the middle of November, and those poor bees never a fly until the last of March or the first of April. When warm weather at last came I thought they were dead, as they did not seem to be flying much, so I did not pay any attention to them until in June. I noticed they were working a little, so I opened up the hive and found them in the upper story. I took the lower story out and left them in the one body. The queen was laying nicely, and I thought they would make a good colony to winter. Along the last of July I noticed that they needed more room. I gave them a super, 24 boxes, and in a few days they had it full. They have made 72 boxes of as nice honey as you ever saw, and are drawing out some starters now, Sept. 2.

Very truly yours,

Geo. B. Howe.

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for $1.25, or club it with the American Bee Journal for one year—both for $1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with $3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.,
144 & 146 Erie Street, • CHICAGO, ILL.

THE Bee-Keeper’s Guide; Or, Manual of the Apiary.
—BY PROF. A. J. COOK.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published today. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE Bee-KEEPER’S GUIDE.

This 16th and latest edition of Prof. Cook’s magnificent book of 460 pages, is neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting new subscribers for the American Bee Journal.

Given for TWO NEW Subscribers.

The following offer is made TO PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal [with $2.00], and we will mail you a copy of Prof. Cook’s book FREE as a premium. Prof. Cook’s book alone sent for $1.25, we will club it with the Bee Journal for a year—both for only $1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,
144 & 146 Erie Street, • CHICAGO, ILL.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

HOWARD M. MELBEE,
HONEYVILLE, O.

[This cut is the Full Size of the Knife.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring steel; and the flint of the handle described above. It will last a last time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the “Novelty” is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the “Novelties,” your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side? The accompanying card gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the “Novelty” must be seen to be appreciated.

How to Get this Valuable Knife.—We sent postpaid for $1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal [with $3.00]. We will club the Novelty Knife and the Bee Journal for one year, both for $1.90.

GEORGE W. YORK & CO.
St., Chicago, I11.
Bee-keeping in the West Indies is the title of a pamphlet of about 80 pages, issued in August of this year by Mr. D. Morris, Commissioner of Agriculture for the West Indies. It is written by Mr. W. K. Morrison, who was engaged for the purpose of preparing the booklet, after visiting several of the principal islands of the group. Mr. Morrison was formerly connected with the United States Department of Agriculture, and is especially fitted for such an undertaking.

In introducing the pamphlet, Mr. Morris says:

"After a careful study of the circumstances Mr. Morrison is of opinion that the outlook for bee-keeping in the West Indies is very encouraging. At present, with the single exception of Jamaica, a bee-keeping industry can hardly be said to exist. At Grenada, St. Vincent, Barbados and Antigua a few bee-keepers were met with, but in the other islands, as at St. Lucia and Dominica, with an abundant harvest of honey-bearing flowers to be found all the year round, little or no attention has been devoted to bee-keeping."

Mr. Morrison gives hints suited to bee-keeping in the tropics, illustrations of the more important implements required, a list of the principal nectar-yielding flowers of that region, and a calendar of bee-terms.

The hope is expressed that the pamphlet will "serve the objects in view, and that a bee-keeping industry of a thriving and permanent character will before long be established in these islands."

Cuba and Jamaica are foremost in bee-keeping among the islands of the West Indies.

The Honey Crop of 1901 in the United States seems to be a rather uncertain quantity, if we may judge from the reports that we hear from various parts of the land. In view of this condition of honey affairs, we requested Messrs. R. A. Burnett & Co. (whom we regard as the largest wholesale dealers in honey in Chicago), to furnish a statement for publication, giving their honest opinion concerning this very important subject. Here is their response:

CHICAGO, Sept. 27, 1901.

EDITOR OF AMERICAN BEE JOURNAL.

There seems to be unusually conflicting accounts of the honey produced and being produced, in the season of 1901. We are just in receipt of a special circular dated at Medina, Ohio, Sept. 25, entitled, "An Unmitigated Shame; More Monstrous Tales About the Prices on Honey." Inasmuch as this circular is to appear in the next issue of Gleanings in Bee-Culture, we will not quote verbatim therefrom, but in the letter that accompanies this the A. T. Root Co. says:

"We believe that when you know the facts you will be governed accordingly." Now we quite agree with this statement—we certainly believe the facts and all that we seek to know (and we judge it to be the same with other people) is, that we want to be sure we have to be correct all the same.

It is probable, from most reliable information that we get, that the Middle and Eastern States have produced more honey than for seasons past, with the exception of southern Wisconsin and northern Illinois. These localities suffered the most severely of any. The Bee-keepers are still holding about the same quantity of bees, but the amount of honey produced this year is said to be more than ever before produced in the middle west.

The State of Texas has produced more honey than California did in ordinary seasons (10,000 to 12,750 pounds). New York and the New England States have had very good yields; so has Mr. Doc. little, of New York, admits that there has been an abundant flow of honey in his locality, in the Ohio and Indiana States, while in locations not far from those favored ones the yield has been light, thus showing that atmospheric conditions have been not always the same over an entire State.

Furthermore, the producers in the less favored sections, where they have not yet been told of their failure to get a crop, thus carrying the idea to those who were more fortunate that perhaps they had all the honey there was to be had. This has tended to make holders of the favored apiarists, resulting in the honey being held off the market longer than usual, as they naturally expected higher prices even than prevailed last year, which season was the nearest to falling below a sufficient supply of any year in the past fifteen.

The Western States, especially Colorado, Nevada, and Utah, are finding that there is not the demand from the East that has existed for the past two years, and are beginning to get anxious about marketing their honey, in consequence of which the associations are making a broad canvass for a possible outlet at prices somewhat near those obtained last year.

If it is true that the newspapers of the country have been telling that there has been a great honey harvest secured this season, it will result in benefiting the producers more than anything else; for, let the public get the idea that honey is plentiful, good and cheap, and they will call for it as would they not otherwise do; for who amongst us does not feel more inclined to purchase an article when it is good and cheap, rather than when it is scarce and dear? We can see great help, if this be true, and the information is broadly circulated, that there has been an abundant harvest of honey, for people must use more of it this season than ever before if the crop of 1901 is to be marketed before the coming crop of 1902 is due.

We are of the same opinion that prevailing prices are not too high, and that honey will be used freely, unless the people begin to believe that there has not been a good crop, but that it is scarce and dear, as the terms "short crop" or "short yield" implies advanced prices to the average mind; hence they look for a substitute, which, once adopted, takes the place of the article that was scarce, until the time for another harvest.

For the foregoing to advise people what to do with their property, but give it as our opinion, which, when compared with others may enable those having honey to sell to ascertain what are the facts.

Very truly yours, R. A. BURNETT & Co.

It will be noticed that Messrs. Burnett & Co. refer to a circular appearing in Gleanings in Bee-Culture. We have thought it best to copy it, so that our readers may have the advantage of both views. It is as follows:

AN UNMITIGATED SHAME; MORE MONSTROUS TALKS ABOUT THE PRICES ON HONEY.

In our last issue it stated that there had been gross exaggeration as to the honey crop of the United States. At that time the inflation buyers claimed a maximum output of only 500 cars; but now they want to have gone 2,000 cars. As stated, there seems to be a combination which has induced some of the daily papers to circulate false statements. They are now reported to have reduced all the prices (of the best, indeed the very best, the entire crop has not exceeded 500 cars, and this year there is a prospect of a failure, if to add insult to injury, they further state that Honolulu honey is being poured into California, and that the prices last year ruled at $1, cents, are now down to less than half that, and they will probably have to go to 25 cents if to add insult to injury, they further state that Honolulu honey is being poured into California.

Such stories have a strong tendency to unsettle the market; and the animus back of it all is very apparent. The Western "bees" are trying to sell, or, at all events, to improve the crop, because prices, which have been lower than the Eastern market as well. If, for example, there were 2,000 cars in California, and as much more of Honolulu honey, it would be perfectly clear that a large portion of it would have to go East. But no one need be alarmed over the matter. The facts are, I doubt whether 2 cars could be scraped up and sent eastward from California, all told. The large baking concerns have laid in quite a stock—probably all they will require; for when the price was down they snapped up every bargain they could get hold of; but now prices with business heads on them are holding the rest of the crop back.

For the present we have our end being as if we were being men on the Pacific coast to make a careful canvass; and it is very evident that the crop is light in comparison with those of the big years. I do not believe there is an aggregation of responsible producers anywhere in California who would guarantee to
day to deliver more than 25 cars, and as nearly as we can estimate they are holding back the further purchases to the extent of 20 to 25 cars. The price realized at the lower end of the market for this is usually the very season for disposing of honey, and it may take months to correct this

The situation in the East, briefly told, is this: There is actually less comb honey produced, and what there is seems to be of an inferior grade. We have advocated in these columns repeatedly that there is enough to go around, and have mentioned the extracted honey in the East; at least, good comb honey sells all the way from 2½ to 3 times as much as extracted for a like quality. The quality of the honey on extracted has become a little unsettled, owing to aforesaid "bees" who not only love honey, but are contriving to get in as much profit thereon as even to make a market where the markets of the East were being glutted; but some of our friends went into some of these markets to buy honey in car lots. Do you believe they could get any? There was not any in sight. To state the matter fairly, there is probably a fair crop of extracted honey of Eastern production; and the prices on extracted will, therefore, rule about the same as the prices for comb honey. The price will be higher at New York than at St. Louis—about 25 cars all told; and this is likewise being held for the same reason. Texas, West Texas, and the South States, will sell it up well; but much of its product will be marketed at home, while Arizona honey, a large portion of it, will have to be sold in the East.

Returning to California, latest advices show that the season has been a flat failure in the central portions of the State. Our men can not find more than three car-loads all told. In Southern California it would be as a rule to allow for 75 cars, if the general reports we get are true, and they come from men who are not inclined to "hull" the market. I know they are very close to the truth, because I was through much of that territory myself, and perhaps two-thirds of the crop had been harvested. I shall send copies of this statement, prepared for me, to the large buyers, and believe will be reliable and honest, and will seek their advice and help.

LATER.—Since the above was written one of our correspondents, Mr. G. C. Dealy, of San Francisco, reports by telegraph that a careful canvass, that he could scarce find, all told, 250 tons (20 cars), and that he is informed from reliable sources, that the crops are much wealthier in the far south and east and very light. Moreover, he finds that some of the buyers, in the paper at Los Angeles, credit to a bee-keeper as many cars of honey as he has in tons. As to prices, the honey is being held firm at 5 cents or more. E. R. Ror.

Like Messrs. Burnett & Co., we hesitate to advocate the large buyers of our readers that have to sell, what to do about marketing it. And yet we think we are safe in saying that whenever you can get as good prices as those of last year, it would be well to accept them very promptly.

Having said that, we may also venture the opinion that the honey price is higher in price, but will likely go lower than the prices quoted now. This we believe because of the feeling that more honey is being held back by bee-keepers this season than in many a year before.

It is exceedingly unfortunate that there seems to be no reliable way in which to get at the exact amount of honey produced. Were it that a possibility, the matter of prices could be more easily be controlled.

A Phase of In-breeding Among Bees

in which there is a difference as compared with other stock deserves consideration. Where breeders of cattle practice in-breeding for the sake of in-breeding certain characteristics, they seem to prefer matting a heifer to her father rather than to her brother. There is a good reason for this. The father and mother of the heifer being of unrelated stock, the heifer is not of the same blood as either, but may be said to have half the blood of each; and likelihood is greater that the heifer which is adopted is not as close in in-breeding as when bred to her brother, which is of the same blood as herself. Now if we have a certain queen of superior blood from which we rear young queens, and then allow these young queens to mate with drones from the same brother, it might look, to a careless observer, the same as breeding the heifer to her brother. But in-breeding is must be taken into consideration, and in reality it is the same as breeding the heifer to her father. For the drone is not of the mingled blood of his mother and the drone with which she mated, but he is of the same blood as his mother. If this year we stock our apiary with drones from a certain queen, and the next year rear young queens from that same mother, allowing them to meet drones of the queens reared this year, we will have practically the close in-breeding of brother and sister that would obtain in cattlerearing, the mating of a queen and drone from the same mother will not be so close breeding.

Weekly Budget.

The Chicago Bee-keepers' Association will hold its next semi-annual meeting on Thursday, Dec. 5, instead of Thursday, Nov. 7. This is the result of a meeting of the executive committee on Oct. 3. The date a month earlier was fixed by the officers of the American Bee-keepers Association. A Stock Exhibition will be held in Chicago Nov. 30 to Dec. 7. Low railroad rates will then prevail, which should greatly assist to swell the attendance of beekeepers.

Look out for a full notice by Secretary Moore, next week. In the meantime, begin to plan your trip to Chicago. No one will be spared to make it the largest and best meeting of beekeepers in 1900—the recent Buffalo convention excepted.

APPRECIATION OF MR. G. C. Dealy.—In writing about his bee-keeping, Mr. Dealy had this to say (see page 618):

On May 22, 1900, I moved three small apiaries, consisting of 57 colonies, another brother of 13, from Walworth Co., Wis., to Wood county, arriving at my destination on May 24.

The weather was considerably cooler than in the previous season in Walworth county, and the losses sustained in moving the apiaries, they were in very poor condition when I arrived. The weather was very favorable the 108 colonies increased to 168, and I shipped two tons of comb honey.

I put the bees in winter quarters, Nov. 25, in an outside cellar. After regulating the ventilation to what I supposed to be right, I left them until spring, returning March 29, when I found the temperature to be 72 degrees in the cellar, and the loss at the outset 9 colonies.

Honey. But because of the high temperature in the cellar during the winter many of the bees became light and left the hive, the hives not having been well put up, and of course were lost. As a result I lost 63 colonies from spring dwindling, a total loss of 22 colonies more than the increase of last year. Those that are left are doing well, and at present there is a good outlook for a fair crop of honey.

Messrs. Salyer, Hyde & Scholl—the officers of the Texas Bee-keepers' Association—were shown on page 609. Since then we have received a few personal items concerning each, but not such as delayed so they could not appear in the issue with the pictures.

All three of those in question are yet young men, Mr. Salyer being the only one married. Messrs. Hyde and Scholl are just out of their teens, and not yet of age; nevertheless all three have done a great deal for Southern bee-keepers, and perhaps there are not many such "youngsters" that have gained so much fame.

Mr. Salyer is vice-president of the Central Texas Bee-keepers' Association the last two years, until elected president of the new State association at the last meeting. He has been in the bee line for many years, combining it with farming and stock-raising, as he has fine herds of cattle.

Mr. H. J. Hyde has been in the bee-business ever since nine years old, helping his father during summer and attending school during winter. As the junior member of O. P. Hyde & Son, and at the head of the queen-rearing department of that firm, besides being an ardent apiculturist, he is able to answer to the bee-papers, he is already well known to the beekeepers of our land. He is of a temperate disposition, abhorring the use of all intoxicants and tobacco. Mr. Hyde is a member of the Baptist church. At home he has held several minor offices of trust, and has been assistant secretary of the Central Texas Bee-keepers' Association, at the last meeting elected vice-president.

Mr. Louis Scholl has been actively engaged in apicultural association work for several years. At the age of 15 he was chosen as the association secretary for his school, and in such, certain clauses in the constitution of the association, restricting an officer to only one year's term, had to be ruled out. He has held his office ever since that time.

His bee-keeping career began while yet quite young, and, on account of his studious habits, he has mastered more about the honey-bee than many another of his age; and if he lives the bee-world may yet hear more of him. He has cast aside great strides towards enviable notoriety, especially among the bee-keepers of the South. His communications to several bee journals have appeared from time to time.

Mr. Scholl is a total abstainer, and an earnest Christian.

In order the able, conscionable management of these three men, the Texas State Bee-keepers' Association should flourish "like the green bay tree."
Convention Proceedings.

Report of the Texas Bee-keepers’ Convention.

By Louis Scholl, Sec.

BEGINNERS RUINING THE HONEY-MARKET.

"How can beginners best be educated how not to ruin a market for bee products experienced?"

D. C. Milam said the selling of honey is the most important subject connected with our industry, the important part being that it depends upon that which brings the cash on which success is based. By producing a first-class article, it should be put up in the best marketable shape, and so as to attract the attention of buyers. The price seems to be almost universal over Texas. Beginners should be taught all this; especially when an experienced bee-keeper has a market established, he should see to the bee-keeper does not throw away their honey, or help them to establish a market for it. When beginners have a surplus of honey during a good year, they just want to get rid of it, and then they do harm through their ignorance.

The demand of wholesale honey is so great that it has never been filled. Of course, while their honey is of such fine quality as to have such a wide reputation, they also have some very inferior honey, from a few localities. Some of it is not even edible, and if it should be put on the market, it would have to be sold for such a person that should happen to eat such inferior stuff would lose all desire for any more honey. Some make a big mistake by extracting too soon, before the honey is well ripened. He cited a case where some honey he bought in barrels, by a dealer who handled honey extensively, and opening a barrel at one time, the vle stuff shot out all over his person and dress, and made him feel so badly that he could not even bear to think about honey—so much so that not honey would ever buy again. Besides this, he gave several other experiences.

He also spoke about organization and the prices of honey. Then all the honey could be bought for a little less per pound to sell again for enough to make sufficient for the trouble, and thus it would save much to the experienced bee-keeper, especially those that have a good market for their product. He said that all honey put up for sale should be a first-class article, and every package should contain the name and address of the producer, to show that it is such. He also told of a firm that bought and sold any kind of honey, just as it would happen along. But that firm does not sell any more now.

W. O. Victor's experience has been quite varied. He related a case where a large bee-keeper sold his honey, of fine grade, for 10 cents per gallon less than wholesale prices, and that in his home market, which ruined his entirely. He tried to buy the honey from this bee-keeper, offering him the real wholesale price, which was 10 cents more per gallon than his wholesale price, but he refused to sell, for the reason that he had to supply his customers with honey.

WHAT IS THE BEST RACE OF BEES?

W. O. Victor said he believed he was perhaps not well informed on the different races of bees, he having begun with the Italians; they treated so well that he stayed with them. He never had any other race in his yards, and hardly knows which is the best race of bees. He told of the many "strains" of Italians, and how they could be bred to possess some of the good qualities. He spoke about the different strains of Italians, the bee-keepers would start to go over everywhere whenever a hive is opened. These call it "race-horses" on account of their running, and thinks it the proper name for them. These he calls out as soon as he comes into the apiary.

The dark, leather-colored Italians he thinks the best, as they are the gentlement bees, sticking to their combs, and for honey-gathering they are the best all-round bees, always ready when honey is to be had, watching even for the bands to open, so that the first sip of nectar might be taken.

Some of the other strains are so vicious that he is afraid of them, for the reason that they are dangerous.

Mr. S. H. Hyde asked if a cross between the three-band Italians and Holy-Lands or Cyprians would not be a good one. Mr. Atchley answered that it would.

L. Stachelhausen said that it took different races for different localities, the three-band Italian not being good for his place, and the Italians, he thought, would have to replace the first one. It might be best to cross them.

H. H. Hyde told of his experience with different races and their average yields, the best being from Holy-Lands. The Italians choked the brood-nests too much.

Mr. Victor said that plenty of room given during slow feeding would not give too many hives, he would always be given a little ahead of time for the flow to begin, and the brood in the brood-chamber should extend from side to side, so the bees are bound to store above. Then always give a little more room than needed.

MISCELLANEOUS MATTERS.

Upon motion of Mr. Davison, it was decided to send four representatives to Buffalo, N. Y., in September, to represent the Texas Bee-keepers' Association, before the meeting of the National Bee-keepers' Association. Udo Töpperwein, G. F. Davison, Louis Scholl and H. H. Hyde were elected as such representatives.

W. O. Victor was appointed a committee of one to prepare a program for the next meeting.
The committee on “Resolutions and Petitions” handed in their report, which was adopted.

The South-Texas Bee-Keepers’ Association, meeting in conjunction with the other associations, asked that they be allowed sufficient time to transact some of the Association’s business, and to elect officers for the ensuing year; also to decide upon a place to meet the next year. Officers elected for the coming year E. J. Atchley, president; W. O. Victoria, vice-president; and J. W. Lewis, secretary.

The next place of meeting will be at Beeville, Tex., on the first Wednesday and Thursday in September, 1902.

The committee judging the bee-keepers’ exhibits handed in their report of awards, as follows:

AWARDS AND WINNERS.

COLLEGE STATION, July 25, 1901.

By Louis Scholl, Secretary-Treasurer, Texas Bee-Keepers’ Association.

Single-comb nucleus, Golden Italian, 1st prize, $2.50—P. Hyde & Son.

Single-comb nucleus, 3-Bland Italian, 1st prize $2.50—P. Hyde & Son.

Single-comb nucleus, Holy-Land, 1st prize, $2.50—P. Hyde & Son.

Swepstakes on bees, greatest number of different races, 1st, Surprise package of valuable articles—O. P. Hyde & Son.

Best section comb honey exhibit—1st, one-comb honey hive—Dr. G. Davidson; 2d, Golden breeder queen—J. B. Salyer.

Best sample case section honey, Special, 50 cents—G. Davidson.

Best sample case comb honey exhibit—1st, 5 pans honey-case—G. Davidson; 2d, Golden breeder queen—J. B. Salyer.

Best sample bulk comb honey, Special, 50 cents—G. Davidson.

Best exhibit bulk comb honey—1st, 5 pans honey-case—G. Davidson; 2d, Holy-Land breeder—J. B. Salyer.

Best spectrum extracted honey, Special, 50 cents—G. Davidson.

Best exhibi-t, 1st, 1st case wax-extractor—Louis Scholl; 2d, Apiary tool chest—J. B. Salyer.

Best sample cake bright yellow wax, Special, 50 cents—Louis Scholl.

Best display honey-plants, pressed and mounted, 1st, Brass Higginsville smoker—Louis Scholl; Special 50 cents—Louis Scholl.

Largest and best display apianary implements, 1st, Cash price, $.50—1st Toeppelewien; 2d, Foundation fastener—O. P. Hyde & Son.

Swepstakes, largest, best and most interesting and instructive exhibit, all things considered, 1st, Cowan honey-extractor—Udo Toeppelewien; 2d, cash prize of $10—O. P. Hyde & Son.

Best exhibit bee-keepers’ supplies, 1st, blue ribbon—Udo Toeppelewien; 2d, red ribbon—O. P. Hyde & Son.

The other business was then all settled, and just before adjournment, upon the entering into the room of the bee-keepers’ section of the Farmers’ Congress, of Prof. Connell, he was presented with a case of beautiful white section comb honey, by the Association, with very appropriate words by Mr. Atchley. Prof. Connell accepted the same with words showing very pointedly how this kindness was appreciated by him, and he thanked them all for their kindness.

The convention then adjourned.

J. B. Salyer, Pres.
Louis Scholl, Sec.

Contributed Articles.

Queen-Breeding—A Review of the Subject.

BY ADRIAN GETAZ.

U.S.T. now, in some bee-papers, a certain class of critics have chosen to criticise our queen-breeder severely, infatiating that they don’t know the fundamental principles of the art. Some have even intimated that a college course of study should have been taken, or at least a full study of Darwin, Huxley, etc. Exactly what advantage a college education would be to a Mr. G. Davidson, with very appropriate words by Mr. Atchley, is a question, the answer of which would be to a queen-breeder, has not been shown. It is even questionable if a full knowledge of Huxley’s and Darwin’s theories concerning the “Origin of Species” and “Descent of Man” would be of any use at all.

Again, the fact that our leading bee-breeder, by not filling the bee-papers with learned (?) contributions on the subject, is not at all a proof that they are a lot of ignoramuses. Some of them undoubtedly know a good deal more than their critics suspect. The fact is, that these critics who speak so learned (?) about in-breeding, and other similar topics, do not seem to know so very much, after all; and while they have succeeded very well in criticising what is done, they have lamentably failed to show what is to be done.

To-day it is raining, and I have nothing pressing to do, so I will take my chances and dabble into the subject, running the risk of showing my own ignorance just for the fun of it.

HEREDITY.

It is hardly necessary to say that heredity is a short word to state the fact that any living being is similar to his father and mother, or ancestors. So a cat is a cat similar to his ancestors. A plant of corn is similar to those that furnished the grain from which it grows, and the pollen which fecundated it (fertilized it). I use common words in place of scientific terms, as far as possible.

VARIABILITY.

But the offspring is never the exact image of its ancestors. There is always some minor difference, sometimes one way, sometimes another, sometimes in one particular, sometimes in another—in size, color, different aptitudes, etc. It is that disposition that enables us to improve our stock. For instance, suppose we want a stock of cattle especially good for milk; by choosing the best milking cow procurable, and a bull a descendant also of good milking stock. In virtue of heredity, their descendants will be generally better milk-producers than any other breed of cattle taken at random. By this ability, some will be better and some not so good, some may be even better than their immediate ancestors, and some may be worse. We choose the best, those, if possible, better than their immediate ancestors, and repeat the process again and again, we will get a stock superior in aptitude to produce milk.

It is almost needless to say that all our noted breeds of stock—cattle, horses, chickens, dogs, etc.—have been produced, I might say created, by that process.

SURVIVAL OF THE FITTEST.

This is called a theory and often criticised or made fun of. But it is a fact, not a theory. Let me give some examples: Suppose some deer were put in a country where there are wolves. Suppose some very fleet on foot and some quite slow in running. The wolves will undoubtedly catch up with and kill the slow runners. The fleet-footed will escape and breed. The result is that the next generation will average a better running stock. Of these, again, the slowest will be destroyed, the quickest remain. The result is that eventually a swift-running stock will be the result.

Take the quails and partridges. They may have been of any and all colors at the beginning. But the bright-colored ones were the easiest to see, and were caught by the hawks and other enemies. The brown and gray remained. Those striped ones, as we now know, are the least distinguishable from the brown earth and dead grasses, and finally remained alone. In domesticity, where all are protected, all colors stand an equal chance, except what choice the breeder may make.

ACQUIRED QUALITIES.

Not only the peculiarities inherent to the animals themselves at their birth, but also those acquired, are, at least to a certain extent, transmitted to their offspring. For instance, the pointer dogs. The first were evidently trained to that mode of hunting birds—a very unnatural one. Their descendants, or rather some of them, inherited that disposition, at least, to some extent. The best were chosen, and more thoroughly trained, and the process pursued until now we have a breed of dogs in which it has become a second nature. There is no doubt that the thoroughly trained race-track geldors for transmitting to his offspring. Take, for instance, the pointer dogs. The first were evidently trained to that mode of hunting birds—a very unnatural one. Their descendants, or rather some of them, inherited that disposition, at least, to some extent. The best were chosen, and more thoroughly trained, and the process pursued until now we have a breed of dogs in which it has become a second nature. There is no doubt that the thoroughly trained race-track geldors for transmitting to his offspring.
different position—for instance, a wild animal be domesticated—and variations in size, color, disposition, etc., will appear at once.

The individuals—like the father and mother, the more strongly and surely will their characteristics be transmitted to their offspring. And if they are very different, all sorts of variations may be expected.

The more alike the characteristics and peculiarities, the more surely will they be transmitted. A "sport"—that is, an animal or plant showing some extraordinary peculiarity—is not at all sure to transmit it to its descendants, while the "fixed" qualities will nearly always be transmitted.

A fixed characteristic is one that has been transmitted from generation to generation either through the natural operation of the survival of the fittest or through the choice of the breeder.

IN-BREEDING.

That is, breeding between close parents or relatives. This is said to be injurious to vitality. The fact is quoted that in natural process of reproduction of plants and animals, in-breeding is avoided. On the other hand, all our best breeds of horses, cattle, fowls, etc., have been obtained by in-breeding. Numbers of bulls and stallions have done service as long as they lived, with their own mothers, grandmothers, daughters, granddaughters, etc.

One thing is certain, in breeding from close relatives, we breed from animals having similar characteristics and same peculiarities, and, according to the above rules, such will more likely be transmitted, and even intensified; for the \( f_{ring} \) of a characteristic generally intensifies it. Now any defect which that breed may have, will thereby be fixed and intensified, until eventually endanger or destroy the very life of the animals themselves.

INFLUENCE OF THE MALE.

In breeding hens, cattle, etc., it is found that the male has more influence on the offspring than the female. This is due in a great measure, if not altogether, to the fact that the male used is of a superior stock, with qualities better fixed and more intense than those of the females. If the process be continued, and the females be bred to the improved stock, and the males of the common stock, the reverse would probably take place. In the human race we do not see that the children inherit more characteristics from their father than from their mother.

INFLUENCE OF THE FEMALE.

The horse-breeders tell us that the male gives the qualities and the female the size. That is true, more or less, of all the animals that are developed in the mother's womb, but it is not so true of any animals.

All those familiar with horse-raising know that a colt at his birth has nearly the full length of his legs; and that when full-grown his height (if he has not been stunted by lack of food or other hindrance) is about twice the length of his legs. It is easy to see that the colt born of a large mare has a start at his birth that he will keep during all his growth.

In plants and animals born of eggs or seeds, such an advantage does not occur.

In bees, the size is limited also by the size of the cell. It is a well-known fact, that drones born in smaller cells than the regular drone-cells are smaller in proportion to the size of the cells.

As to Bees.

In our attempts to improve our races of bees, we have to meet several difficulties that do not occur in other lines:

1. We have not the same control of the reproductors.
2. If we desire to improve a herd of cattle we have the choice of the very individuals. We choose the best cow, and a bull descended from a superior stock. In improving our stock of bees, we want to improve the qualities of the workers. But we can not use the workers themselves. We have to fall back on their mothers, and use for reproduction drones and drones of their mothers have produced good workers, and take our chances.

2. We have only an imperfect control of the drones, and if we could breed from an individual drone of our choice, however, it is extremely improbable that the drones of his sons would give better workers than that one? There is nothing to show. At best we could eliminate the weakest and undersized one. The only point where "hand-picking" of drones could help is in regard to color. The yellowest drones will undoubtedly produce the yellowest workers.

3. We are to work in the same line as Nature. In improving cattle, for instance, in getting up a good milking stock, we are developing a quality that in the wild state was completely unknown, and with careful results. In the wild state, the animals (something like the Texas steers) have developed chiefly hardiness, health and strength. If we were to take the Texas stock and try to improve the size and shape of the animal, we would make but little headway, because Nature has already developed them almost, and perhaps up, to the limit attainable.

First of all, what we want chiefly is hardiness and honey-gathering qualities; that is, the very qualities that Nature has been developing for thousands of years, and we may expect that the limit has been nearly reached, if not altogether. We may perhaps increase the size of the bees and length of tongue.

CONCLUSION.

After all is said and discussed, all that is to be done is to get the queens and drones from the very best colonies obtainable, and rear the cells under the most advantageous conditions of warmth, feed, etc. It is needless to say that underized or defective queens (and, if possible, drones) should be rejected.

That's all.

Knox Co., Tenn.

Size of Hives Not Necessarily in Accord With Lay-ing Capacity of Queen-Bees.

BY G. M. DOLLITTLE.

A CORRESPONDENT writes thus: "I would like your opinion concerning the H. B. R. L. (R. L. being Largaasen) hive, so generally recommended, the same would, if badly occupied with weak-combs, contain about 115 sq. inches, and give about 8,500 cells. From this we must deduct at least ten percent of the space for the usual supply of honey and pollen, leavings, etc., about 2,000 cells. Allowing 21 days from the egg to the time the bee enters its cell, and one day for the bees to clean the cell, and for the queen to lay in it, again, we have an average of about 200 cells for the queen to fill per day. Now, in 2,000 eggs the usual daily laying capacity of a queen in a strong colony? If not, should any queen be considered a queen that annually produces less than the number of eggs it is laid for? This is the question that the reasons, or lack of reasons, given in this paper, may help to determine what size of hive to build the comb in. Please write me a letter."

I did not know that it was necessary to make our hives, as to size, to accommodate the prolificacy of the most prolific queens, nor do I so think. Suppose a queen could lay 5,000 eggs daily, on an average, as some think possible. What is the price or worth of those eggs? Does the sum and substance of bee-keeping depend upon keeping all queens employed at egg-laying to their fullest capacity? Bees, when they come on the stage of action at just the right time, are very valuable, but eggs are of no value, only as they tend in the direction of producing these valuable bees. Aye, they tend toward positive disadvantage, and, to take away the profit in this way, those who have only, as they look toward the end of producing the required bees in the field at the time of the honey harvest. Here is a point often lost sight of by the large-hive advocates.

Eggs cost practically nothing; but as soon as the bees begin to perfect them toward other bees, then they begin to cost; and if this perfecting is going on to any great extent at a time when the perfected product is placed on the stage of action, either before or after their presence in large numbers is needed, we not only have the cost of perfecting to pay for, but the cost of their consuming, after being perfected, as well. This consuming part we always have to pay for; but we willingly do it at any time when the product of the individual is of value. There is no reasonable objection to this; but I can see no object in doing this at any other time, simply that the extra laying capacity of any queen may be gratified. A hive that is large enough to gratify the greatest aspirations of very prolific queens, at the times of the year when the necessity of the colony is present, of course, but I have no objection.

But I can see no object in doing this at any other time, simply that the extra laying capacity of any queen may be gratified. A hive that is large enough to gratify the greatest aspirations of very prolific queens, at the times of the year when the necessity of the colony is present, of course, but I have no objection.

From all past experience I think that 2,000 eggs per day would be a good mean average for any queen. Rain, cold, or other disturbing influences often retard the activity in the hive, and of the queen, and thus it happens that at times the best of queens often does not lay more than 1,000 eggs in one day. While, of course, the queen, if she can multiply this number by four, and still have plenty of room in a hive which will give an average of only 2,000 daily.

Then, again, as two and one-seventh generations of bees can be brought on the stage of action to where one steps off, we find that, in a hive giving an average of 2,000
bees daily, we can have in that hive, barring accidents, if the hive is properly managed, 105,000 bees on the stage of action right in the honey harvest, when their productive power is the greatest; and at such a time such a number of bees are a host to roll honey into the sections, with the combs all filled with brood below; and this rolling of honey into the sections means the rolling of money into the beekeeper's pockets, from which come the necessities, comforts and luxuries of life.

Experience has shown the men who are advocating an eight-frame Langstroth hive that such is the best, as this keeps the frames full of brood, and puts honey into the sections.

Again, suppose a colony of bees having a good, prolific queen is given 30 Langstroth frames, using but eight to start with, and adding two or three at a time, as the bees can occupy them, until the 30 are all in, it will be found that such a queen will lay from 4500 to 5000 eggs daily, during the best part of the egg-laying season, and die of old age or exhaustion when from 12 to 18 frames old; while with the eight-frame brood-chamber she will give as good results in comb honey each year, and live from three to four years. With the large hive the bees are quite likely to get the start of the queen, and commence to store honey in the brood-combs before entering the sections at all; and in such cases the bees seem loth to go into the sections, but continue to store honey in the brood chamber in preference to going into the sections, thus crowding out the queen with honey, in the combs which ought to be occupied with brood, till we have, as a result, very little section honey in the fall, and a colony in poor condition for winter. Besides, it is well to remember that all queens are not equally prolific, and while 20 percent of our queens would keep the brood-chamber of a ten-frame Langstroth hive properly supplied with brood to give the best results in section honey, the other 80 percent would not be prolific enough to do so; hence, in the majority of the hives in the apiary, we should have a condition working against our best interests, which could not be overcome by the extra amount of comb honey produced by the 20 percent, whose queens were prolific enough to work in these ten-frame hives to advantage.

For these reasons it would seem best to adopt a size of brood-chamber which any and all queens, that are worth keeping at all, would have occupied with brood at the commencement of the honey-flow, thus securing the best yields of surplus section honey at all times.

Because a queen may lay 5000 eggs daily by using plenty of comb-capacity and coaxing, it does not necessarily follow that it is to the best advantage of the apiculturist to accommodate or even coax a queen to bring her fullest laying capacity to the front at any time. Queens, in any well-regulated apiary, are among the smallest part of the expense incurred, while labor, hives and combs go toward making up the largest part of the same.

For these reasons I claim that the capacity of the queen should rather be above the capacity of the brood-nest than below it, so that all combs may be fully occupied with brood before the honey harvest arrives. Unless this is the case, the outside combs continue, in most cases, to be dead capital (honey) from year to year. However, all our questioner (or any one else) has to do is to use part ten-frame and part eight-frame hives in the apiary, when a little time will satisfy him which is the better for his locality.

Onondago Co., N. Y.
such a low moral level I should rather expect him after awhile to transfer his nationality to the more prosperous nation, and next to offset them by carrying steppings in the opposite direction. Page 562.

TRADE BULLETIN QUOTATIONS.

I should suspect that the trade bulletin of a big city would be less reliable on honey prices than the leading honey-dealer of that city—liable to print the figures of somebody’s g Essex, or figures adjusted from one sale at abnormal prices. Page 566.

*The Home Circle.*

Conducted by Prof. A. J. Cook, Glencoe, Calif.

MOTHER.

This is surely the most precious word in the home circle. I am reminded of a sweet, wholesome, delightful story that I lately read in a magazine. An acquaintance of a motor-man was riding with his friend on a trolley car as the latter guided and directed it through the streets of our great metropolis. He noticed that the city was very unusual so he, starting and stopping and in making the numerous turns he was not thrown or pushed or handled at all roughly as is the wont so frequently in our rides on the electric cars. He asked him if it was not an unusual experience to a young fellow to come out to the fortunate rider on this special car. His friend explained as follows:

After he had run the car for a time his mother came to keep his home for him. He longed to take her on his private trips and he would have enjoyed her in his car every day. He proudly took her with him the first day after her arrival, and to give her a rare treat he gave free rein to the current that was silently and invisibly hurrying them over street after street on his beloved home. In the kindred affection, he learned for her dear boy she led to conceal a mortal fear, and serious pains and aches, as she was pushed, knocked and jammed hither and thither as they flew around bends or stopped and started in a break-neck fashion.

On the morrow she so studiously concealed her aches and pains, and serious lameness. He was saddened, and greatly disappointed, that his precious mother wished no more to go with him, as this would turn his work into pleasure, and rare pleasure if it would bring joy to his beloved parent. Finally he learned through a third party, of the shock and inconvenience which his mother had received on the occasion of that first ride. He was dumb with sorrow, chagrin, and contrition. He successfully urged a second ride, and now his care more than equaled his previous rashness. Caution made the start and stop so gentle that those riding felt no jar; the turns were so skillfully made that no push was felt. The fond mother felt no fear, and suffered no harm or inconvenience. She now takes daily rides to the joy of both her own and her son’s heart. The son added: “In all of my trips now, I wonder if some other son’s mother is not in my keeping, and so the cran and leavers are ever pulled out to check the jar and lessen the shock as the turns are made or the speed varied.”

Oh! how few mothers really know or realize the wondrous influence they exert to make the world brighter and better.

THE CALIFORNIA RED-HEADED WOODPECKER.

This is one of the several beautiful California birds that belongs to the order Pic. These birds are quickly known, as two toes oppose two others on each foot, which enables them to hold fast to fence-post or tree-trunk. Their beak or bill is a well fashioned chisel, by which they loosen the knot that leads to grub, or fashion their nest. Their long tongues are barbed that fishhook-like they may catch and pull out the coveted grub or caterpillar. Mr. and Mrs. Red-head are alike capped with red, and, like many other birds, as instance in blackbirds and robins, are quite exclusive in their attentions the one to the other.

Mr. Woodpecker’s name is not Roberts. He would not be excluded from his seat in Congress, if elected thereto. Mr. and Mrs. Red-heads are probably the most harmonious and industrious birds working together most delightfully and industriously. They bore numerous holes in quite regular form and position into the great mountain pines. They then hire away to seek the rich, nutritious acorns which they crowd one into each hole, so compactly that one needs his knife to loosen them. Often a very large acorn is such a misfit that the hole must be greatly enlarged, and then one of the pair holds the nut while the other makes a nest. An unusual bird. Calla, a sound hole, or a nest, is the name of one of their other birds to aid. As soon as the hole is sufficiently large, all return to their own work except the two that then adjust the acorn snugly, and proceed with other nuts. Later, as food is scarce, these nuts are eaten, and form the hearty meal for this faithful and deserving man and wife bird.

THE OJAI.

Queer word is that. We pronounce it O-hi. It means “carpet nest.” Indeed, it is strewn with the tufted grass and lovely woods which enfile the north and southern sides. It is in Ventura County, hardly more than a half mile to the north of Ventura by the Sea.” In its nest-like form it is similar to the oriole of the East. A ruga is the name of an oil-cushion where I am now writing, and El Cajon. The Ojai, however, is peculiar in fondly bearing numerous great, spreading, beautiful live-oaks. Their nest-like valleys, which nestle at the foot of a great ring of mountains, more beautiful than the trees and shrubs, are exceedingly lovely. They hold the fortunate people who call them home, with a fascination that makes them ever afterward impatient of any other home. I never feel more close to the verge of envy than when I visit these gardens is somewhat southerly.

I often find my lips whispering: “Oh! always to look upon this grandeur.”

BOOTS THAT SHINE.

It is my privilege as conductor of farmer’s institutes in Southern California, to be much with the professors of that institution, of which every Californian is so justly proud. In California, where we have little or no rain from April to October, the dust gets very assertive. To keep one’s boots bright with an innumerable amount of polishing is no mean accomplishment. One of my colleagues, who happens to be my companion for these two weeks, has that exceptional faculty. He tells me that Mrs. —— often holds him up to the children—our two boys—as an example that they should the better exert their thoughts to bring the shoes whine. How blessed the mother who can always say: “Do as thou seest thy father do.” in her efforts at discipline.

Questions and Answers.

Conducted by Dr. C. C. Miller, Marengo, III.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—E. H.]

Questions on Nectar-Yielding Plants.

I want to keep a few colonies of bees, and want to provide a pasture for them. What is the most durable and quickest seeds to sow?

How long does it take buckwheat to come into bloom after coming up in (very) seasonal weather? How long does it stay in bloom? Is it fit to cut and feed to stock?

Alfalfa down here doesn’t yield any honey. What is the difference between white sweet clover and white clover?

I had about an acre of crimson clover in the spring which the bees worked on as long as it lasted. I had the seed mixed with alfalfa, but it was no good. Is there anything you can suggest?

Answers—Answering your questions somewhat out of their exact order, I can not say how long it is from coming up till bloom of buckwheat, never having taken exact figures. They should be harvested at the proper season for standing, three or four weeks might not be out of the way. But that guess may be considerably out of the way. As to length of blooming season, my guess would be also three or four weeks. Very likely both of these guesses might be lengthened. The blooming season is very often closed by the
first frost. I think buckwheat is never cut up and fed to stock, but the grain is harvested.

The difference between white clover and sweet clover is about seven feet. White clover grows close to the ground and has its blossoms as gobular heads like red and crimson clover; white sweet clover grows tall and has its blossoms singly all over the bush. Very likely sweet clover and crimson clover will be as good as anything you can sow. crimson blossoms early, and probably closes about the time sweet clover comes in bloom, and the latter will bloom till after several frosts. If harvested for hay before it comes in bloom, the full blooming will be later than if left to its own course.

Queer Idea About Rye Flour and Bees.

How do you fix rye-flour for bees to make comb for their hives? I can not find any one that knows anything about rye flour. I have read that they make comb out of rye, but I don't know what to do. I have a quantity of rye flour.

GEOLOGIA.

ANSWER.—I think you must have been misinformed. Rye flour is used sometimes as a substitute for pollen, but not as a material from which comb can be directly produced. Bees make comb only as it is needed, and it is honey more than pollen that is used in its production. It will be wise to feed rye flour to bees only in the event of a scarcity of pollen, and it may most likely make a better use of your rye flour than to feed it to bees.

Swarming of a Divided Swarm.

After making a divided swarm, as described by Mr. Deolittle on page 478, is there danger of them swarming any more than that season, provided they are supplied with enough supers and sections to keep them from getting overcrowded?

ANSWER.—I should say there was no more danger of swarming than the danger in the case of a natural swarm.

Honey-Dew for Winter—Insuring Bees.

1. I have 48 colonies with plenty of bees and honey, but I am afraid they will not winter well, as they have gathered considerable honey-dew, or bug-juice, if I may call it so. Have been through the month of September, and I think it will last as long as the weather stays warm enough for the bees to work. Will they winter all right if I use a Hill's device and a cove to cover them, and packed on the outside with forest leaves on both sides and back about four inches thick?

2. Is there such a thing as insuring bees against loss in wintering in this locality? If so, where and what do they usually charge per colony? Say from Nov. 1 to May 1.

ILLINOIS.

ANSWER.—1. There is a great deal of difference in honey-dew. Some of it will do well for winter stores, and some of it is little better than poison. It would be impossible to say which kind your bees are getting, but if bees have generally wintered well in your locality you may be on the hopeful side, for it is quite likely that they have had the same thing in other years.

2. I don't know of any such insurance, but will yield the floor to any one who does.

Queen-Introduction—Pure Italian.

1. I was rather unfortunate in my queen-rearing during the late summer. Out of 14 queens emerging during June and the early part of July, all but two were missing before they began to lay; after that they did better. I had to give some colonies three cells before I got a queen to lay, and in one case I had to introduce a bought one. The weather during the early part of summer was very cool, in only five or six days up to nearly the middle of July did the highest temperature reach 70° F., and it was seldom much over 60°. Do you think that would account for the loss of queens? If not, what would?

2. I have bought three queens and introduced them safely, but I noticed, in one case, on two occasions, where I looked into the hive, a number of cells with two, three, and, in a few, four eggs; on the last look I saw worker-brood capped over, looking all right. Would you consider that queen a faulty one?

3. I think I saw recently in one of your answers that if a drone was dark it was not pure Italian. I got a tested queen last year from a well-known Italian firm, and while all the workers have the three bands, the drones are quite dark, some showing a dash of dark gold and some none. Would you consider that queen pure Italian?

BRITISH COLUMBIA.

ANSWERS.—1. Weather seldom warmer than 60° and never more than 70° would be enough to account for your loss.

2. It is not very unusual that a queen on first introduction after a journey in the mails does something out of the common line, and afterward does her work in good shape. It is just possible, too, that the workers rather than the queen were at fault. If bees were few in number, and if the queen was a good layer, she might need more room to lay than the space covered by bees, in which case you might find a plurality of eggs in a cell. At all events, if you later found sealed brood in regular order you need have no anxiety.

3. If I used language to give you the impression that I thought a dark drone was proof of impure blood, I advise you not to put too much reliance on the statement. The looks of either queen or drone can hardly be taken as a test of purity. Some excellent Italian queens have been very dark, and the same may be said of drones. The workers are the ones by which purity is judged.

Don't Feed Sugar to Complete Sections.

1. I have 20 supers about half full. Can I mix honey, sugar and water and let the bees finish them? If so, what proportion of each would be best?

2. There are plenty of drones flying now. What does that indicate?

INDIANA.

ANSWERS.—1. Don't think for a minute of using even the smallest proportion of sugar to finish sections. Just now about the greatest foe-beekeepers have to fight is adulteration, and for them to band together in a national association to fight it, and then feed sugar themselves to get sections finished would be about as consistent as is the Christian man who prays 364 days in the year for the downfall of his enemy, and then on the 365th day votes to support it. If you want to feed to have sections finished, use diluted honey. Very few, however, have been able to make it pay. Better sell at reduced price sections that are not finished, and let the bees empty out any that are less than the size of a 36th. Pile up the sections you want bees to empty, and allow entrance for only one or two bees at a time. If you allow a larger entrance, the bees will tear the comb to pieces.

2. It does not have any special significance; at least it may not. Sometimes colonies that have a good queen will suffer drones to continue. At the same time it may be that some colony or colonies have laying workers or drone-laying queens.

Killing off Drones.

What is the cause of drones in some of my colonies? One of the strongest has lots of them. They are killing off the drones this early, Sept. 24.

INDIANA.

ANSWER.—There is nothing strange about it. The strongest colonies would not feel in so much of a hurry to kill off their drones as the weakest ones, especially if the strongest ones had queens and were superseding them.

German or Italian Queen.

Is the queen enclosed herewith a genuine German, or is she crossed with Italian blood?

CALIFORNIA.

ANSWER.—I don't know. You can't decide by the looks of a queen as to her blood. You must have her worker progeny to judge by. I have seen imported Italian queens as dark as the sample sent, while their worker progeny were beautifully marked with the three yellow bands.
REVERSIBLE WALL MAP
OF THE
UNITED STATES AND WORLD,
WITH SPECIAL INSET MAPS OF
China, Cuba, Porto Rico, The Philippines, Hawaii, and Alaska,
Especially prepared to meet the demand for a first-class map that will give a quick, general idea of location of events the world over, and particularly to the United States and our territorial possessions. Very useful in every home and office.
60 x 46 INCHES IN SIZE.

ELEVEN BEAUTIFUL COLORS.

Best and Most Necessary Map
Ever Issued.

No Home or Business House
should be without it.

The Plates
are works of art. The engraving is plain, bold, and decisive. The color work is elegantly contrasted, but not gaudy.

Perfection and Artistic Elegance
a salient feature of this map not approached by any similar publication.

Marginal Index
is one of the invaluable features. It gives an alphabetical list of countries, their location on map, style of government, population, area, products, minerals, imports, exports, etc.

It has been pronounced a Photograph of the World
The 1900 Census of the largest American Cities is given.

One side shows a grand map of our great country, with counties, railroads, towns, rivers, etc., correctly located. The other side shows an equally good map of the world. Statistics on the population, cities, capitals, rivers, mountains, products, business, etc., a veritable photograph of the UNITED STATES AND WORLD.

The map is printed on heavy map paper and is mounted on sticks ready to hang. Edges are bound with tape.

1901 EDITION—Every reader should consult it every day. The plates show all the new railroad lines and extensions, county changes, etc. Special attention is given to the topography of the country; all the principal rivers and lakes, mountain ranges and peaks are plainly indicated. The leading cities and towns are shown, special attention being given to those along lines of railroads. The Canadian section of the map gives the provinces of Ontario, Manitoba, and British Columbia. With nearly all of Quebec and New Brunswick, the county divisions being clearly marked. The Southern portion of the map includes the Northern States of the Republic of Mexico, and the Bahamas.

On the reverse side is the Library Map of the World. The largest and most accurate map on Mercator's Projection ever produced. The political divisions are clearly defined and beautifully outlined in colors. The ocean currents are clearly shown and named. Ocean steamship lines with distances between important ports are given. A marginal index of letters and figures enables one easily to locate every country in the world. A series of short articles in alphabetical order is printed around the border of this map in large, clear type, containing valuable information concerning agricultural, mining, and manufacturing statistics, also the value of imports and exports in dollars. The area division, form of government, and chief executive of every country in the world is given up to date, also the names of the capitals and their population. The Inset Maps are elegantly engraved and printed in colors. They are placed in convenient positions around the United States map, and will be invaluable to every person desiring a plain understanding of our possessions. An inset map of China on the World side of map adds its value.

Two maps on one sheet, all for only $1.50, sent by mail or prepaid express; or we will forward it free as a premium for sending us Three New Subscribers at $1.00 each; or for $2.00 we will send the Map and the American Bee Journal for one year.

Address,

GEORGE W. YORK & CO.,
144 & 146 Erie Street, CHICAGO, ILL.
Bees In Fine Condition.

The honey season is over and the bees are in fine condition for winter. Our crop was 23 tons from 300 colonies, spring count, and increased to 425 colonies. Two of us did all there is to do, and found time to do considerable on the farm besides. L. L. Andrews, Riverside Co., Calif., Sept. 11.

Bees and Pear-Blight.

I notice in the American Bee Journal an item in the column of 'bees and plants' which I would like to have some one confirm before it gets into print. I see some think the bees spread it, and some think they do not. I am of the latter opinion. I have a pear orchard and in the last two years the pear blight has appeared on every pear tree. I have the Bartlett and another late pear; this year some of the trees died almost to the roots, while some of the Bartletts blighted just a little. What made me think this was not the spread of disease, is a tree that stands close to others that did, that does not show a bit of blight, and is loaded with pears, and a tree of the same kind, about 20 yards away, died clear down. Another instance is a seedling I get some distance away. It is loaded with Bartlett pears. It never had a blossom, and never died. It took the disease, and died. Now, if the bees spread the blight why did this tree, and any other Bartlett not take it? All were loaded this spring, even to those that died, showing the bees had worked on them, and it is true about the fruit needing bees to cross-pollinate. And why did the seedling take it? Can you answer that? Cutting off the diseased parts seems to stop the disease to some extent here.

Lathu Co., Idaho. F. C. Holbrook.

Poorest Honey-Year in Nine.

We have no surplus honey here this season, but bees are doing well now. It is the poorest honey-year we have had in central California in the nine years I have lived here. J. W. Steele, Merced Co., Calif., Sept. 1.

Troubled With Grasshoppers.

The bees in this part of California have done very little this year, a living, I must say. I fed mine until the latter part of June, but I am pleased to say they are doing well now, and living up well to keep off grasshoppers. They did not get until the latter part of August. The cause, I think, was the grasshoppers on the alfalfa fields; the trees were likewise covered with little jumpers, and the bloom blasted. The bees would sit out on the alighting-board and act as if they were looking for a job. But now that is all changed; they are out by the time the sun is up, flying hither and yon, gathering the nectar from the alfalfa and carpet plant. Most of the grasshoppers have disappeared.

I have just received the American Bee Journal: it is full of good things for the bee men and women. I like it very much; in fact, it is almost as good as I expected it to be. I have tried the straw for robbing, and find it very good. It has stopped it every time for me.

The Seasons of 1899 and 1901.

I wish to remind the bee-keepers of the Mississippi valley what educators to us the year 1899 and 1900. We had so much honey in 1899 that we had no surplus honey from other sources, but plenty to keep up good strength from July 1 to late fall, while we were able to get some honey from grandmother's bee-keepers in the states south of us because the colonies were strong at just the right time.

Because of a severe drought, 1901 has yielded only a light crop from clover, ending two weeks earlier than usual, leaving nothing of much account for bees to work on from July 15 to Aug. 3, a period when very few eggs were laid by the queens—a period just when all queens should have been filling every available cell with eggs. Our bees came up to an abundant flow from heartsease with only a little over half the strength main- tained in 1899, where there has been, for some, on the very colonies of at least $800, which could have been remedied if foreseen. Stimu- lating the colonies for spring, I believe we gathered an equal or greater return from 1901 than we did in 1899.

Of the Evening Primrose Family.

I send a sample of leaf and blossom of a weed that grows sparingly around here, on which bees work prodigiously. I have no doubt they gather both pollen and honey. I do not know, and have found no one who does know what it is, or how to identify it. I hope you will be able to show me the same species. It is a small plant, like a little gailardia in size. My attention was first attracted to it by the hum of the bees on it, and I subsequently found it was a very pretty plant, like you to tell me through the General Items column of your excellent paper what the name of the weed is, and its value, as I wish to save seed if it is con- sidered a good honey plant.

J. O. MEYER, St. Louis, Mo.

Please mention Bee Journal when writing.

taken and read with great pleasure the American Journal for about four years, and I have enjoyed its weekly visits immensely. Though I have used only 25 coloums, but I am prepared to increase when spring comes again. Not boasting at all, but I have the name of keeping bees in Missouri, being on of the seven informed bee-men in this section, and I give the credit to the American Bee Journal, as this is how that was begun.

This has been an exceedingly poor honey-year in northeastern Missouri, owing to the drought that has prevailed since in April. Yet I am not as hopeful as some, and for getting the things that have passed I look forward for better seasons and greater blessings.

Shelby Co., Mo., Aug. 3.

[The plant belongs to the Evening Primrose family. Its botanical name is Gauges biennis, and it goes by its first name - Gauga.

These are the author on writing - honey-producing plants do not speak of it as being especially productive, but bees are not easily deceived, and if they are interested in the flower no doubt it is furnishing them honey or pollen, probably both.--C. L. Walton.]

Some Points in Indoor Wintering.

Some that are of interest are given by Mr. Darling, in the Canadian Bee Journal. formerly great stress was laid upon the covering in winter, so that the right amount of upward ventilation could be secured, but late winter events have caused to the conclusion that Mr. Darling has reached, that it is not a matter of special importance how the air is introduced into the hive, only so there is enough of it, and if plenty of good air can enter below, the upper part may be as tight as a drum. Mr. Darling says:

In regard to packing, I have used sawdust and cork dust, and I have tried wintering outside at all; I live where it is too cold—too near the North pole—but for years I took off the propolized sheet on a cotton cushion filled with sawdust or cork dust (I brought the sawdust from the sawmill and the cork from the saw-mill). I fail to see very much difference in their effect, only I thought the sawdust from the sawmill was quite as warm, and the cork dust is a little drier. There is so much evaporation from bees that if you take a little piece of lath and leave it lying on top of the cushion for a number of hours, you will find it cover on all, if you lift that piece of lath up any time after it has been there a few hours, there will be a wet spot on that cushion of the size of that piece of lath. If nothing touches the cushion it is dry all winter long, and sawdust is dry. I have often put my hand under it and it is warm and cozy on top of the sheet, if there is anything under.

I had formerly tight bottom-boards, and that is the reason I took off the propolized sheet. Lately I have taken off the bottom-board, left the propolized sheet on, and put the cushion on; that allows no moisture to get through, but I raise up my hive at the front—I don't like going to the back to let them down—and I find that they winter just as well and better than they did without the propolized sheet, and with the bottom-board tight there is no danger of there being any dampness above, and my rooms and bees are as dry as they were when the boards were fastened.

Queens Fertilized in an Upper Story. The Mr. Wardell, the man who has charge of his colonies, has evolved a system of having queens fertilized in upper stories, that is a perfect success. I do not speak of this as a system, as he may be the more wholesome honey to sugar, the very best quality of alfalfa honey I have received from you is better suited than the honeys of more marked flavor, according to my taste.

C. C. MILLER.
McFarley Co., III.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, III.

stand of there being from 25 to 30 pounds of honey left in the brood-nest, which he does not want there, that amount all goes into the store, where he does want, and he can command the very best market price obtainable. When I asked Mr. Burt if it was not easier for him to have the honey in the brood-nest, he said it was not, according to his practice. "I prefer," he said, "to sell my honey, what I do not use at 15 cents per pound and then buy syrup at 3 or 4 cents; and I not only make a good trade, but I give the bees a much better feed. While good honey does well in winters, yet there are occasional ones when the syrup-fed colonies come out much better. No, sir," he said, "I do not want any honey in the brood-nest in late summer, I prefer to feed sugar syrup, for then I know my bees have the very best food for winter."—Gleanings in Bee-Culture.
AMERICAN BEE JOURNAL

HONEY AND BEESWAX

MARKET QUOTATIONS.

Chicago, Sept. 19.—No. 1 white honeycomb is selling at 85c per pound, with occasionally a cent more being obtained at times. We also note that No. 1 does not grade No. 1 selling at from 130c to 140c, with occasional sales as high as 150c. We understand that there are various kinds selling at 100c. Extracted in moderate demand at from 50c for the various kinds down to 25c for some white and basswood bringing 5c; light amber ranging up to 11c; dark amber from 25c to 30c; wax firm at 28c.

R. A. BURNETT & CO.

CINCINNATI, Aug. 10.—The honey market is rather dull on account of the warm weather. Extracted is selling from 25c to 50c; No. 1 white sells 60c; better grades alalfa white-water from 75c; white clover from 85c. Fancy white honeycomb sells from 135c to 165c.

BOSTON, Sept. 27.—We quote our market as follows: Fancy white in cartons, 10c; No. 1, 12c; No. 1, 14c, Extracted, white, 90c; light amber, .6c; dark amber, 30c. Blaker, Scott & Lee.

ALBANY, N. Y., Sept. 19.—We quote: Fancy white, in cartons, 9c; No. 1, 11c; No. 1, 13c; No. 1, 15c; Extracted, white, 9c; light amber, 7c; dark amber, 30c. H. R. Wright.

OMAHA, Aug. 8.—New comb honey is arriving by express in small quantities from Iowa and Colorado, and will undoubtedly prove a re- tail way. California extracted honey is being offered carlots at 45@45c per pound, I.o.b. Cal. and 35c on freight. The demand for all of any sales have been made thus far. The proposition of extracted honey seems to carry large this year in Colorado, Utah and Californ.

P. O. MILES.

NEW YORK, Sept. 27—Comb honey is now beginning to arrive in large quantities, and, as a rule, quality is fine. The demand is good, and we quote it as follows: Fancy white, No. 1, 1c; No. 2, 12c, and amber, 11c. No buckwheat is on the market at present, but is coming within a week or so. Extracted is selling close to 50c per pound according to quality, and Southern honey in barrels at 85c and 90c per barrel. Beeswax dull at 25c. W. W. McClenahan & Bro.

DE MONES, Aug. 7.—There is very little doing here in new crop of honey. Some small lots of near-by produced comb honey are on the market and selling in a retail way at $3.50 to $3.75 per pound. Our quotations in this line before Sept. 1, our market does not consume a great deal of extracted honey.

F. C. KELLY.

DETROIT, Aug. 12.—Fancy white honey comb, 140c@145c; No. 1, 138c@141c; no dark to quote. Extracted, white, 65c. Beeswax, 20c. M. H. Hunt & Son.

BUFFALO, Aug. 14.—Quite a good demand for fancy, 160c@175c, and lower grades, 125c@14c; old neglected. Advise moderate prices. Request our list of new as yet. BATTISON & CO.

SAN FRANCISCO, Sept. 4—White comb, 10c@12c; amber, 75c@ dark, 60c@75c. Extracted, white, 55c@60c; light amber, 45c@; amber, 45c. Beeswax, 20c. Arrivals and spot offerings are of rather moderate volume, but there is as much or more on market the case happens to be unex- pectedly guessed. To secure liberal wholesale customers we would advise moderate prices to the user of buyers. In a small way for especially desirable lots slightly higher figures than are quoted are received.

KANSAS CITY, Sept. 14.—Up to the present time only small lots of new comb honey have been on the market, and these met with ready sale on the basis of 150@160c per pound for fancy. For next week there is no prospect of anything being sold. We have not had any orders and the quotations are issued at $1.00@$1.25 per case for lots of small size, which would be equal to about 40c on the market. The future of a firm market is anticipated. Inquiries for extraction and for comb honey still seem to have their ideas too low. In a small way 85c@90c is quoted.

A New Bee-keeper’s Song—

“Buckwheat Cakes and Honey”

Words by EUGENE SECOR.
Music by GEORGE W. YORK.

This song was written specially for the Buckwheat Cakes, and was sung there. It is written for organ or piano, as have been all the songs written for bee-keepers. Every home should have a copy of it, as well as a copy of

“The Hum of the Bees in the Apple-Tree Bloom”

Written by EUGENE SECOR and Dr. C. C. MILLER.

Prices—Either song will be mailed for 10 cents (stamps or silver), or both for only 15 cents. Or, for $1.00 strictly in advance payment of a year’s subscription to the American Bee Journal, we will mail both of these songs free, if asked for.

RED CLOVER QUEENS

BLACK ROCK, N. Y., Sept. 3, 1901.

FRIEND ERNEST—I will try and tell you what you want to know about that queen. I got her of you in 1899 as a premium with GLEANINGS. I never saw a small colony of bees build up as that one did. In the spring of 1900 they came out in fine shape, wintered perfect. I raised them up in May and gave them 8 frames more so the queen would not want for room. I never saw such a colony of bees as they were in June, and they were actually storing honey when other bees in my yard were starving. No! they were not robbing. I never saw those two best colonies of mine trying to rob. THEY CERTAINLY WORK ON RED CLOVER. This is no guesswork, as I have seen them. As you know, the past two seasons have been very poor, and what honey my bees did get in 1900 candied soon after cold weather set in. I packed this colony in a cheap hive and left them out, thinking that such a strong colony would winter perfect. The snow came on the middle of November, and those poor bees never a fly until the last of March or the first of April. When warm weather at last came I thought they were dead, as they did not seem to be flying much, so I did not pay any attention to them until in June. I noticed they were working a little, so I opened up the hive and found them in the upper story. I took the lower story out and left them in the one body. The queen was laying nicely, and I know they would make a good colony to winter. I got them at the end of July I noticed that they needed more room. I gave them super, 24 boxes, and in a few days they had filled. They have made 72 boxes of as nice honey as you ever saw, and are drawing out some wave this, Sept. 2.

Very truly yours,

GEO. B. HOWE.

Membership Dues, $1.00 a year.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

Note. - One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one of the buttons as I have noticed people to ask questions about the busy bee, and many a conversation was started and wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a most attractive button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Langstroth ON...
The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for $1.25, or club it with the American Bee Journal for one year—both for $1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with $3.00. This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO. 144 & 146 Erie Street, - CHICAGO, ILL.

THE— The Bee-Keepers' Guide; Or, Manual of the Apiary.

- BY-

PROF. A. J. COOK.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to need introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPERS' GUIDE. This 10th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to present subscribers only, and no premium is also given to any two new subscribers—simply the Bee Journal for one year:

Send us two NEW SUBSCRIBERS to the Bee Journal ($3.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for $1.25, or we will club it with the Bee Journal for a year—both for only $1.75. But surely anybody can get only TWO new subscribers to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. WILL YOU have one?

HOWARD M. MELBEE, HONEYVILLE, O.

THE NOVELTY POCKET-KNIFE.

Your Name on the Knife. - When ordering, be sure to say just what name and address you wish put on the Knife.

The Noveltv Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown above.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire, the lining are plate brass, the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a lifetime, with proper usage.

Why Own the Noveltv Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Noveltv" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Noveltv," your Pocket-Knife will serve as an identitv; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faithful, but cannot convey an exact representation of this beautiful and AIRY KNIFE, as the "Noveltv" must be seen to be appreciated.

How to Get this Valuable Knife. - We send it postpaid for $1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with $3.00). We will club the Novelty Knife and the Bee Journal for one year, both for $1.50.

GEORGE W. YORK & CO., St., Chicago, Ill.

For please allow about two weeks for your knife order to be filled.
No Foul Brood—A Correction.—On page 627, we called attention to a reported case of removing foul-brood hives, combs, etc., from Michigan to Clyde, Ill., near Chicago. The owner of the alleged diseased material, mistrusting that he was the one referred to, called at our office for an explanation of the matter. We told him that our authority for the statement made were the foul-brood inspector of Michigan, and another man in that State.

He stoutly denied that any foul-brood material had been shipped by him, and said that the goods were still in the railroad car at Clyde, the car being unopened on account of some question about the freight charges.

In order that there might be no further cause for disagreement, we suggested submitting the matter to Mr. N. E. France, the famous inspector of apiaries for Wisconsin. He was immediately sent for. He came at once, and the owner of the car of bee-material, with Mr. France and the writer, spent several hours in examining very carefully all that the car contained, and found no evidence of foul brood whatever.

It seems that there were some foul-brood combs, etc., in the apiary from which the carload was taken, but those were not shipped. Hence, the unfortunate error.

We make the above explanation for two reasons: First, because we do not wish to accuse any man unjustly in public print; and, secondly, to show how easy it is to be mistaken.

As we did not give the name of the bee-keeper in our first reference to the matter, of course we omit it now. The carload of hives, frames, etc., was shipped from Rapid City, Mich., instead of Evart, as was stated on page 627.

We are more than pleased to have the matter end as it has, as doubtless will be all the bee-keepers in and about Chicago; for there is already enough foul brood in this vicinity without importing it from another State.

But, all the same, there should be a law in every State prohibiting the removal of any apiary, or part thereof, without first securing a State certificate granting permission, and also assuring that there is no disease.

Old vs. Young Queens for Breeders.—Editor Hutchinson calls for the experience of his readers as to the comparative value of old and young queens as breeders. In view of the fact that H. Edwards, of England, says that all queens making a record have been reared from the eggs of a comparatively old queen. One would naturally expect that the time of life at which the offspring of any mother would have the greatest vigor would be at the time when that mother herself is in the greatest vigor. A queen can do little toward making a record for herself, usually, during the same season in which she is born, for few queens are born before the swarming time, and the season will be well over before the entire force of the colony consists of her offspring. Her record will not be made before the end of the second season, and after distinguishing herself in her second season she is used as a breeder in the third season.

So it comes about that those who select the best to breed from will use comparatively old queens, and this may go far to account for the fact that Mr. Edwards’ best queens came from comparatively old mothers. But if he had reared queens from one of his breeders while she was yet in her first year, and as yet had established no reputation, might they not have been just as good as those she produced a year or two later?

Prevention of Early Swarms, says the Bee-keepers’ Review, is secured by some Ontario bee-keepers by using bottom-boards of wire-cloth, the abundant ventilation at least retarding swarming. Some might like this better than raising the hive on blocks.

Position for Bee-Escapes.—Almost universally they are put in the center of the escape-board. It was suggested in the Bee-keepers’ Review that one corner of the board is the better place, because when bees become excited about getting out of the super they run around the edges. Yet E. W. Brown, of northern Illinois, reports that in cool nights a cluster of bees would remain in the center all night if the escape was in a corner. Perhaps the best way would be to have an escape in the center and one in the corner.

Plurality of Eggs in a Cell is nothing very unusual when a prolific queen is in a limited brood-rest, but the cells containing more than one egg each are worker-cells. It seems, however, that exceptional cases occur in which a normal laying queen will lay the second egg in a queen-cell, according to the following from Gleanings in Bee-Culture:

A rule that I supposed without exception was that, if you found more than one egg in a queen-cell, you might be sure of laying workers. The other day I found two eggs in a queen-cell and a good laying queen present.

"Bees do not fling invaribility."

Thickness of Top Bars.—S. T. Pettit champions in Gleanings in Bee-Culture top-bars less than 3/8 thick. He quotes a correspondent who says:

"For a number of years I have been using a top-bar ¾ inch thick and ½ wide, and not a burr-comb on a single frame in eight years’ use."

This agrees with Mr. Pettit’s theory that the width of the top-bar and not the thickness is the essential thing to prevent burr-combs; although Mr. Pettit himself finds it necessary to use a thickness equal to ¾ to prevent sagging.

Dr. Miller says he still wants thick top-bars even if they make no difference about burr-combs, because the thick top-bars make so great a difference between brood-combs and sections that the bees will not carry up black wax to darken the sections.

Mr. Pettit thinks this point can be gained better by using queen-excluders. Editor Root thinks that ¾ top-bars gave more burr-combs in their apiary than 3/8.

Prevention of Winter-Breeding.—An article from Wm. McEvoy, in the Bee-keepers’ Review, gives his way of preventing the bees from beginning to rear brood in January when wintered outdoors. He thinks that by preventing the bees from starting brood-rearing in January—a thing that often occurs with bees wintered outdoors—we not only save store, but the lives of many of our best colonies, which often dwindle down and out in spring from the large amount of brood-rearing that they do at a time when they ought to be at rest. His plan of prevention is to crowd each colony upon five combs about the first of October, and seal each one of the five combs being sealed right down to the bottom. If any combs are unsealed, he feeds till the bees will take no more. This leaves no room for brood-rearing.

Cane vs. Beet Sugar.—Some discussion has taken place with regard to the propriety of using refined beet sugar for feeding bees, and some bee-keepers have felt uncomfortable because they had no means of determining whether granulated sugar was made from cane or beets. Bee-journals across the water have insisted that sugar made from beets was not safe food for bees. The following letter in Gleanings in Bee-Culture seems to teach that beet sugar is all right:

Mr. Huber Root called my attention to an article published in Gleanings Aug. 15, and asked me to read it and give my opinion of some of its statements. The writer, W. K. Morrison, seems to think that sugar made from cane is better than that made from beets. I do not know how he or any one can know when he gets granulated sugar whether it’s made from cane or beet. Of course, if he
sees the name of a sugar-factory of Nebraska, Colorado, or Michigan, on the sack in which it comes, he knows that he has beet sugar, but, if he has no way of knowing, for, even though it be from the refineries of Havemeyer or Arbutte, it may be from either source, for these refineries handle raw bate sugar from Belgium, Holland, France, Austria, and Russia, as well as raw cane sugar from Java and the Indies. One of the most remarkable characteristics of sugar, which the writer is that cane sugar is sweeter than beet sugar, "just as Jersey milk is richer than Holstein milk, and it seems, that cane sugar is a higher price." In the first place, I will say that cane sugar does not command a higher price than beet sugar; for in determining the price of sugar there is no question of its source, but of its quality. In the next place, I will say that the characteristics of sugar from whatever source, depends upon its polarization of purity of sugar. As the chemical form of the molecule, the same (C_{12} H_{22} O_{11}), and their physical characteristics are both the same, it results that neither one, or the other can be said to be sweeter. The simile can not hold for the reason that, while sugar is a fixed chemical compound of so many atoms of carbon, hydrogen, and oxygen, with certain physical characteristics resulting from the atoms of the molecule, the cellular qualities of sugar, on the other hand, is a variable physical combination of many chemical compounds; and while the sugar in the central parts of the molecule of sugar would make it other than sugar, there can be a great variation in the quality of milk, and it would still be milk. It might contain more or less water, more or less casein, more or less fat. The writer of the article claims that Dr. Wiley says that beet sugar is cane sugar, and cane sugar is beet sugar. I think that Dr. Wiley could say that. He might say that they are identical, or that beet sugar is cane sugar, but that cane sugar is beet sugar, for the reason that "cane sugar" is the common name of the article which is chemically known as "saccharin," and "saccharine" is the common name of the article chemically known as "glucose." The name "cane sugar" was given, at a time when the only known source was cane; but since then it has been found in other grasses besides the cane, and in a number of roots, as the carrot, parsnip, turip, and notably in the beet. The writer of the article further states that, by this definition, sugar is any material which is 500 times sweeter than ordinary sugar, ought to be cane sugar also, but it is not so, it is not! Sugar is not a sugar at all, having none of the characteristics of sugar except that in a dilute solution it will sweeten the tongue, while in concentrated form it would be very bitter, and it is in no sense a food, as is sugar. I do not know what he means by "the same process of reasoning," but certainly no process of reasoning could class saccharin as sugar.

MELVIN R. GILMORE.
Buffalo, N. Y., Aug. 31.

It seems that after reading this letter one may feel easy about the matter, especially after the following assertion of Editor Root:

I will reiterate what I have repeatedly said in these columns, that beet sugar, such as we have used for the last 20 years for feeding our bees, has been eminently satisfactory.

The Best Hive-Cover. — There has been some pleading for a hive-cover that would not leak, warp, or twist. A strong cleat at the ends will prevent warping, but it will not prevent twisting. Two thin boards with an air-space between them, the grain of the one boards at right angles to the grain of the other, the whole glued with water-proof paper, will probably solve the problem, the air-space at the same time making the cover warmer in winter and cooler in summer. The demand, however, for a cover of this kind has so far not been as might be supposed. Gleanings in Bee-Culture says:

Some days ago Mr. Culvert sent some samples of covers, such as I described, to a number of prominent bee-men, as well as dealers, located in different parts of the country, and good many of the replies have now been received: and nearly all favor a single-board cover in place of the double board with air-space. Indeed, the Excelsior cover with sides and ridge-board is considered quite good enough, and it seems to be that a double cover would be better on all accounts.

Westward Ho! — Editor Root predicts that within 10 or 20 years the larger amount of honey will be produced west of the Missisipi; intensive agriculture making bee-keeping less and less profitable in the East, while in the great West there is much land that can never be cultivated, but will produce good crops of honey. We'll see.

Getting Combs Built to Bottom-bars, says J. C. Derwiler, in Gleanings in Bee-Culture, is easy with wired or unwired frames, but the work is more expensive in the upper stories. That has been well known for a long time, but Editor Root might have taken the space for a foot-note to say that in most cases it would be inconvenient, and in some cases impossible to use such frames in upper stories, leaving the advocates for foundation-plaits perhaps the only ones who can get combs directly built to the bottom-bar without sagging in a lower story.

Wanted—A Foul-Brood Law and Inspector.—An Illinois subscriber, who finds good reason to suspect that some serious disease is getting a foothold in his apiary, says that disease akin to foul brood is by no means uncommon in his locality, and adds:

"We, as well as the rest of the State, badly need a law and an inspector, the same as Wisconsin or Canada has had."

Some bee-keepers will not agree with him.

One will say:

"I've been keeping bees 25 years and have never seen a case of foul brood, pickled brood, black brood, or any other kind of brood but healthy brood. That's the use of pastis. The expense of an inspector so long as the disease is not known in the State only in exceptional cases.

To this it may be answered that one reason for the need of an inspector is the fact that without an inspector the scourge may exist and flourish for a considerable time in any given locality without its existence being generally known. It may be a great deal cheaper—undoubtedly it is a great deal cheaper to have some one constantly on the lookout to prevent the spread of foul brood, than it is to stamp it out after it has obtained a firm foothold. It is better to be at the expense of insurance than to run the risk of being burnt out. Decidedly, our correspondent is right. Illinois ought to have the law and the inspector.

The Chicago Convention, to be held at the Brilliant H. O., double board, 56th and Fifth Ave., on Thursday, Dec. 6, promises to be something of a revival of the old North-Western. It is hoped that all who can do so will arrange to attend.

Weekly Budget.

DR. C. C. MILLER, and his sister-in-law, Miss Emma Wilson, were in Chicago on Thursday of last week, attending the American Sunday-School Missionary Conference, where Miss Wilson read a most thoughtful paper on "Quarterly Examinations in the Sunday-School." Both Dr. Miller and Miss Wilson are enthusiastic along Sunday-school lines, and are already leaders in certain important things in that direction. They find that Sunday-school work combines well with bee-keeping. At any rate, both are successful in their devoted hands.

A MAGAZINE FOR COLLEGE MEN.—The Business Side of a Great University," by President Harper, of the University of Chicago, is the opening article in the College Man's Number (Oct. 12) of the Saturday Evening Post, of Philadelphia. Pa. Theodore Roosevelt, Harvar 80" is the title of an entertaining paper on the President's college life, by his friend, Owen Wister. Other strong features of this number are short stories by Ma. A. Nurse, and Frank Norris, and a page of droll "Nature Studies," by Oliver Herford. This number will be of unusual interest to all college men.

MR. N. E. FRANCE, of Girtus Co., Wis., when here to make the inspection referred to on the previous page, of course called at our office. He reports about half a crop of honey in his apiaries this year. He also said that there would be less foul brood if all bee-keepers would read the bee-papers. Quite a testimonial to the value of such publications. Mr. France, in his recent work in his position as inspector of apiculture, but has met many difficulties. His pathway will have to be made easier, or he will decline to continue in the work. Wisconsin bee-keepers can never repay him for what he has done in their interest. Neither can they find another man who will be likely to do the work so well, and with so little friction all around.

Quantity of Nectar in Blossoms—Water Used by Bees.

BY C. P. DADANT.

Do all the blossoms yield nectar that are visited by the bees for nectar? In other words, are the frequent visits of bees to blossoms out of which they secure no pollen an indisputable evidence that they are gathering nectar from them? This point is still being debated between two progressive apiarists of France—L’Abbe Multier, president of the Association of Bee-Culture of Haute Marne, and G. Collot, the editor of the monthly Revue de l’Apiculture Pratique.

L’Abbe Multier holds that in his section of country, although the bees work faithfully upon the basswood bloom, they never or almost never harvest any nectar from this tree. He holds, that although the basswood blossoms attract the bees, they go there and remain, in a sort of drug, instead of working. Indeed, it was proposed in a bar-room, while the bees that go to other blossoms go back and forth, from the hive to the field, and vice versa, and over and over without stop.

If the above-named gentleman had not in many instances shown his observing mind, one might be tempted to think that he misrepresented matters, but that is out of the question. He is not the first who has noticed that the bees may spend much time on blossoms without apparent results. The Revue Internationale had, years ago, seen the bees eagerly at work upon the blossoms of the Eryngium Gainteum, and had ascertained that they secured nothing worth mentioning. He had marked some of the workers while they were there, with a slight flour-dust, so as to be able to follow them in their flight, and had actually seen the same bee on the same bunch of blossoms, working faithfully and busily, for five consecutive minutes. It is very evident that the quantity of nectar secured, though sufficient to keep up the life of the bee, was so insignificant as to leave its honey-sac unfilled.

I mentioned this fact in my letters from Switzerland last year, in the American Bee-Journal.

When the Echinops Spharceaphalus was accidentally discovered to be a valuable honey-plant (?), the gentleman who made the discovery noticed the numerous visits to the plant by the bees, and sat down to an experiment as did Mr. Bertrand, only, instead of marking a bee and watching it, he marked off the workers while they were there with a mark, and saw if the same blossom was visited 1600 times by bees during the same day. This experiment, reported to the North American bee-keeper’s congress, brought the Echinops before the public in the United States, and a general rush was made towards the production of this plant. But it was since ascertained that not only was this a noxious weed imported from France—a sort of dwarf thistle—but it was also found, that, although the bees were always upon it when in bloom, yet no apparent results were secured. At least this is the final verdict, as far as I have heard. Mr. Bertrand, through his experiments in Switzerland, had already come to this conclusion, and I have heard from the Echinops and the Eryngium as not worthy of cultivation.

In the case of the basswood, the accusation of uselessness is not to be considered, except in instances like the one I have mentioned, where the trees are not numerous, and honey-producers are not short of clover honey in others. And the odor of the basswood honey, as well as its taste, can not be mistaken for any other. It is stronger in flavor than the perfume of the basswood itself, and stronger, too, than any imitation perfume, but a rank and almost disagreeable odor, which has caused its being classed as secondary in quality.

But the fact that the basswood bloom is evidently a useful honey-producer does not, after all, destroy the evidence, that in many cases the bees work upon blossoms which attract them by their pleasant smell and retain their attention by probably supplying them with enough nectar for their daily sustenance. Perhaps there is a remunerative quantity to make these blossoms desirable or entitle them to a place among our domesticated plants.

But plants and trees which furnish a supply of honey in certain localities under certain conditions, prove useless in places, and it is not to be ascertained of his situation and act accordingly.

DO BEES USE WATER TO COOL THE HIVE?

I see the above question put by J. A. Gerelts, page 566. In this article Mr. Gerelts connected with the American colonies from the combs melting down, and that he was told that the want of water by the bees was the cause of this. Let me give him our experience on the subject.

In 1878, if I remember rightly, we had established an apiary in the same woods, in which the bees have been in an old French gardener, about six miles from our home. The hives were in the yard near the house, and only a few of them sheltered from the rays of the sun by apple-trees. A small number of the hives had roofs, the others (new hives) were not sheltered in any way, for we had never before experienced any loss from heat, and had no idea of the possibilities.

During that summer the trees were tremendous, and we were hoarding the bees in the house. We were unable to put the honey-boxes fast enough to keep the bees with room, and the combs were exceedingly heavy. I remember going to that apiary at one time with six or eight extracting supers, and being unable to get them down. The surplus supers were filled with empty honey-boxes and all were filled at my next visit, a few days later.

These bees needed no water supplied to them artificially. There was a large creek in close proximity, and they had no great difficulty in getting it along finely at that place on their own resources in that line.

One day during the hot weather, I received word by a messenger sent by my old friend, the gardener, that something was wrong with the bees in the house. I was unable to go there for two days, in spite of his warning, and when I arrived on the third day I found five hives entirely empty, and some 15 others with from one to five combs broken down. The bees in the partly broken hives were already re-building the lost mass of piled-up broken combs, mixed brood, pollen and honey. But the five hives that had broken down entirely had nothing left but a pile of debris, dead bees and rotting brood. Remember that all these hives had supered on, some, one or two—super of our large-size Queen, containing when full some 60 or 65 pounds, and the body of the hives probably contained as much. All this was gone, and very certainly the most of it had run in the garden and been used for manure.

A few bees were found gathering straw out of our hives, that is, over the oil-cloth, at the top of the hive and under the cap, summer and winter, and it was on the suggestion of our old friend, the gardener, who had been put to work on mats all his life when gardening in Paris. He knew how to make them, and made for us a large lot; he said that in Europe they used them to keep away the frost, to shelter their plants from the heat of the noon sun, to cover their glass hot-beds on cold nights, and for many other purposes connected with gardening.

We have used these mats ever since. They not only keep off the heat of the sun in summer, but they retain the heat in the winter. They are good non-conducting shelters, and absorb moisture. We make them of what is known by us as "slough", a plant of the botanical name of which I believe to be "Spartina," a tall, wiry grass well known to any one who lives along the Mississippi. This material is stronger and tougher than straw, and mats made of it would last for ever if we could only bind them with indelible twine.

We had made also, of some of these mats, of large size, two feet high, by six or seven feet in length, and had used them to wrap up our hives for winter. But they were so cumbersome that we were forced to alarm our rats and mice destroyed the cord with which they were made. I believe it would pay to keep such mats in a safe place so as to use them for wintering.

The most important thing that we have had to prevent a recurrence of the accident above mentioned. Whenever the hives suffer from the heat, we raise them from the bottom-board so as to give plenty of ventilation. This we think is as necessary as the use of a shelter from the sun. We also use roofs (portable roofs made...
of rough boards) over all of our hives, and since we have used these precautions we have not had any accidents of this kind to suffer.

EXHIBIT OF BEES AND HONEY AT A FALL FESTIVAL.

BY JOHN R. SCHMIDT.

A NOVEL and interesting exhibit in the Pure Food Department of the Cincinnati Fall Festival was the display made by Mr. C. H. W. Weber. In a tastily decorated booth a complete line of bee-keepers’ supplies, consisting of the latest hives, utensils, and equipment was on exhibition in the pursuit of modern beekeeping, together with a nice display of comb and extracted honey put up in a most inviting and catchy way, as shown.

The exhibition attracted such universal attention, and was so much admired by the thousands of visitors, that it might be well to go into details somewhat as to its make-up, thereby possibly enlightening some interested readers who may improve upon the same at the next fair or exhibition coming his way.

The display being in a corner of a building, the two white-washed walls were well hidden behind a mass of choice comb honey in cases, tiered up over five feet high. Behind each of these, bottled honey was arranged, showing the different sizes, and also the special registered labels, a distinct marking for that kind of honey only. If proven otherwise, a $100 offer is yours, puts some significance into the meaning of these labels. The honey-cases and the bottles were encased by numerous one-pound car-tons colored a light lavender on two sides, and lettered in gold, signifying the contents a gift-edged product.

Potted plants (natural palms) furnished a florist, and placed in the center of the display, added much to the appearance and helped to enliven the exhibit; not to say a word about the bees, which made a “hot time” caused by the ever mischievous boy, this time with a sharp lead-pencil, who knocked apart the wire meshes at the entrance and allowed bees to escape before being discovered. Luckily, only one souvenir was carried away.

The three well-known hives, viz: 8 and 10-frame dove-tailed, Danzebaker, and the Langstroth portico, all complete and pried up, were set up in a neat as a pin, were placed near the rear wall, where they showed up to good advantage. The Cowan extractor, comb foundation, supers, smokers, and many small articles too numerous to mention, made up what may be called the foundation of the exhibit. Last, but not least, each tele- phone subscriber was furnished with an extra instrument in his exhibit free of charge, thus establishing perfect outside communication with almost every booth in the building, through a miniature exchange, which was on exhibition and illustrated the working of this wonderful instrument. This highly appreciated convenience came in especially handy when the bees escaped for it was telephoned instantly to the office and the scene was saved.

The most conspicuous place of the exhibit—the front—was occupied by two small tables, one of which contained a model 8-frame dovetailed hive having four glass sides. The hive was perfection in the full sense of the word. It contained a full colony of plain 3-handled Italian bees upon 8 frames of comb, with brood, honey and everything just as you would find in any prosperous colony. The upper story consisted of a 4½ x 4½ x 3½ plain section super, with fences partly cut away on either side to show the sections of honey in the various stages of completion.

In order that the queen might be seen at all times, a one-frame nucleus was shown, making it easy to keep track of this important individual.

Another nucleus illustrated the rearing of a queen-bee from the tiny egg to the matured product ready to begin her supreme reign, or be sent through the mails in one of the well-known cages. This was also shown and fully explained.

It may not be wise to say that these observatory hives were very attractive in appearance, which was due to the perfect workmanship. Instead of being painted they were nicely varnished. The top, lower-story and bottom-board were held securely together with nickel-plate fastenings, giving the whole a handsome appearance. Double-weight glass on the sides and ends of the full colony, and on the sides of the nuclei, made things as plain as day, and revealed the mysteries of the bee-hive to hundreds

with their strange, and, many times, ridiculous ques-tions.

Now, thoroughly aroused as to how bees “make” honey, the interested observer passed on to the other table, where a neat and polite young lady attendant was in charge of two large glass vessels of honey, distinct in quality and flavor, viz: the famous Colorado alfalfa, and white clover honey. Each who wished to sample was provided with a small, flat piece of white basswood, which served as a spoon. After once used, the piece was done for, and dropped into a receiver. This method not only avoided a lot of mushy work, but was extremely sanitary, and many sampled the honey who otherwise would not have done so. Quite a number of orders were booked for delivery, not saying anything of the one-pound sections and the bottles sold every day at the exhibit. On an average about three gallons of extracted honey was consumed every day from the sample table. Each little stick held, at most, half a teaspoonful of honey (many times less), so it is easy to imagine how many dips were necessary to take away three gallons of honey.

After the first day it was found absolutely necessary to restrict some of the children “unaccompanied by parents” who were especially fond of honey, for they actually could not decide on which should be the last dip.

An unusual and unexpected coincidence developed in the form of a biscuit-baking booth next door, which adver-tised a well-known flour, and gave away hot biscuits and coffee. The hot biscuits and the honey soon developed a mutual attraction, to the tune of several angry calls over the telephone for “More sample honey to the exhibits! Quick!” A fortunate misfortune which may be answered by yes and no.

The exhibit was a success in every way, and the howling success of Cincinnati’s great annual show was largely due to the exhibitors taking such an interest in their exhibits, as this one did in his. May it only serve its purpose well, and help bring “more business” to the bee-keeping industry, as well as in other pursuits.

HOW I MANAGED A SWARM OF BEES.

BY DR. E. GALLUP.

On April 19, 1919, I caught a medium swarm of bees. Now I propose to tell, for the instruction of the beginner, how I handled those bees.

I hived them on six empty frames. After seven days I began to move the outside frames one at a time, into the center of the cluster, so the queen would occupy it with eggs, and have the bees build all worker-comb. It had a young queen and probably was a second swarm. Bees left to themselves, especially with an old queen, usually build more or less drone-comb at the outside of the cluster.

On May 24 I had 14 frames all filled with worker-comb, and the queen had occupied them as fast as built.

On May 13 I moved the queen and two frames of brood into an empty hive, moved the old or first hive about the width of it to one side; set the hive containing the queen near enough to the position of the first hive so as to throw
Preparing Bees for Winter—A Conversation.

BY G. M. Doolittle.

HELLO! What are you doing with the bees this morning? I supposed all work with them was over for this year.

"In this you are mistaken, Mr. Smith; for, in my opinion, to reap the best results in wintering bees, September is the ideal month for the job. Of course, they should be fed in case of any mishap. But I could never see the necessity of the first thing pulling smoke in at the entrance, whether it is required or not. It looks to me like carrying your whip, and every time you get ready to do a job, the bees thin up, and the smoke, put on a good, smart cut with it for fear they will kick or hook. When I use smoke I usually just run a little at the top of the hive. Let the bees keep on at work, and out in at the entrance. By some doing so we can keep them gentle.

Bees that were in good condition have done remarkably well. The honey season is nearly over now. The loss in the three dry years that have passed has been very heavy in the mountain apiaries, where there was no irrigation. They will work in the valley until September.

Orange Co., Calif., Aug. 3.

Oct. 17, 1901.

AMERICAN BEE JOURNAL 663

the most of the working force into the new hive; placed an empty frame between the two full ones, and adjusted the division-board. I sent for an Italian queen for the old hive. I have two boys, to the land and trees in the entrance, we should disturb them and stop their labors entirely for the time, but as we handle them, keep them right on at work, and they are not disturbed a particle. If every time we look at them, we allow them to be over-smoked, they should soon have them so cross that it would be dangerous for the children to go about them.

When I had 125 colonies about the house, I never had my own or the neighbors' children stung by them at all. We opened one hive too early in the morning, nor too late in the evening, when the weather is too cool.

I commenced this article some time in May, and it is now Aug 3. It was mislaid and forgotten.

Always have your smoker ready, in case of any mishap. But I could never see the necessity of the first thing pulling smoke in at the entrance, whether it is required or not. It looks to me like carrying your whip, and every time you get ready to do a job, the bees thin up, and the smoke, put on a good, smart cut with it for fear they will kick or hook. When I use smoke I usually just run a little at the top of the hive. Let the bees keep on at work, and out in at the entrance. By some doing so we can keep them gentle.

Bees that were in good condition have done remarkably well. The honey season is nearly over now. The loss in the three dry years that have passed has been very heavy in the mountain apiaries, where there was no irrigation. They will work in the valley until September.

Orange Co., Calif., Aug. 3.

October and November, by being obliged to eat poor, thin stores, this causing bee-diarrhea on account of the bees not being able to hold their feces, because they cannot evapo-rate the moisture. For the first month of this time they are anxious to learn about the bees, so I have opened both hives three and four times a week, and sometimes twice a day, to take out the combs and show the bees at work, the queen depositing eggs, how the workers unload their pollen, etc. One can scarcely find a swarm that is not more or less crossed with Italians.

In examining those bees we have not used a bee-veil or one particle of smoke at any time. Now, if I should, as much as an Italian queen, put her in the new hive, to the land and trees in the entrance, we should disturb them and stop their labors entirely for the time, but as we handle them, keep them right on at work, and they are not disturbed a particle. If every time we look at them, we allow them to be over-smoked, they should soon have them so cross that it would be dangerous for the children to go about them.

When I had 125 colonies about the house, I never had my own or the neighbors' children stung by them at all. We opened one hive too early in the morning, nor too late in the evening, when the weather is too cool.

**Burr-Comb With Honey Between Super and Brood-Frames.**

I am a beginner in bee-keeping, having 16 strong colonies, in hives having 8 Hoffman frames with ¾-inch top-bars, with Ideal supers for section honey, and I am bothered very much with burr-combs full of honey being built by the bees between frames and supers; built so solid that it is impossible to remove them without lifting the frames, although the bees had plenty of room in the supers for storing honey. What will prevent bees from building burr-comb and storing honey between frames and supers?

**SUBSCRIBER.**

**Answers.**—Is the space between each two top-bars and the space over top-bars ¾ inch or a shade less? If so, there should not be very much trouble with burr-combs. I hardly know what can be the trouble. Perhaps there was an accumulation of burr-combs over the top-bars from former years. If there are burr-combs over top-bars when you put on supers, you may be sure the case will not be getting better, but worse all the while. In any case, the burr-combs are there now, and if let alone will be there in worse condition next year. I have been putting up supers or boxes, to scrape the tops of the top-bars clean with a sharp garden-hoe. Put your foot on the top of the hive at one end, and hoe toward you. Let an assistant play the smoker to keep the bees down out of the way.

**Foul-Broody Frames—Moving Bees a Long Distance.**

1. Can frames from foul-broody colonies, after the wax and honey have been melted out in a solar extractor (the heat of which is so intense as to cook eggs hard), be safely used in the apiary again?

**Answers.**—1. **I think** it would be safe to use such frames again, although very unsafe to use the honey again, and consequently unsafe to use the frames if any honey were left on the frames. That excellent authority on foul brood, Wm. McEvoy, tried to make it very clear to us at Buffalo that it was safe to use, without destroying, hives that had contained foul brood. Other authorities have insisted that it was unwise to use such hives, but the fact that under Mr. McEvoy’s instructions at least 5,000 such hives have been used with no evil results, makes it seem practically safe to use them. So I conclude that frames with no honey on them might be used without harm. While I think it might be safe to use such frames, I do not think it advisable. Mr. McEvoy advises using the hives and burning the frames, of course saving the wax.

2. The two items in the preparation are to provide abundant ventilation, and to provide against moving of the frames. One way is to provide ventilation by means of wire-cloth to cover the entire top of the hive, having a frame two inches deep on which the wire-cloth is fastened. If fixed-distance frames are used, all that is necessary to fasten the frames in place is to put wedges between the dummy and the frames or side of hive. If loose-hanging frames are used, you may wedge, between the frames, sticks long enough to reach to the bottom of the hive and project above the top-bar. Or, you may fasten the frames in place by driving small nails into each end of each top-bar, not driving the nails entirely in, but leaving them out enough so they may easily be drawn after the journey is over.

It will be well to study up what is said in your textbook on the subject.

**Drones—Honey-Boards—Sweet Clover, Etc.**

I have an apiary of 60 colonies that I am running for pleasure and a desire to study the nature, habits, etc., of the honey-bee. I have nearly all the standard books on apiculture, but can’t solve many little things that develop, and therefore I have to apply to our best authority, and wish to ask:

1. Why is it that several of my colonies lately have turned out a full force of drones, after killing them off in July, as is their customary habit here and elsewhere?

2. I don’t think I have seen a drone since some time in the latter part of July (it is now Sept. 23), and a few days ago I was strolling through my apiary, and all at once the peculiar note of a drone on the wing attracted my attention, and, on examining, I found the place alive with them, but they seemed to be confined most to certain box-hives, and are again being driven off by the bees. How do you account for this?

3. Some of my colonies are storing honey in their supers, while the majority of them haven’t stored any after the principal flow closed, which is generally about the last of June here. I have tried baiting them, still they seem to be basely engaged, and carrying in pollen.

4. A drone would not seem to act for a covering for supers to act as a honey-board, Is there any objection to it?

5. How do you prevent the honey-board being stuck to the frames and the frames over?

6. Suppose you use a piece of crocus-sack for a covering in place of a honey-board, would it be a good way to give the bees air to raise up the top by placing two cross-sticks under the top, raising it an inch or so? Would that increase the vitality of the honey?

7. Will yellow and white sweet clover yield nectar in this climate? If so, how long after sowing? When is the best time to sow it?

**Answers.**—1. I don’t know. I may give a guess at it. It is possible that in your locality, as in many others, you suffered from the terrible July drought, causing the bees to kill off their drones. Then when rains came and started up a moderate honey-flow, eggs were again laid in drone-cells. It must be remembered that each year about one quarter of the drone-cells are superseeded, and the drones usually done somewhat late in the season, so if a colony with a superseding turn of mind had been left by the July drought without any drones, there would be nothing left for them to do but to rear drones.

2. The difference in conditions accounts for the difference in behavior of different colonies. A colony with a young queen might be likely to rear no drones after July, while a colony with an old queen that it was trying to supersede would be sure to rear them. At the time you saw them the bees were probably killing off the drones from the supers at such times the drones being driven out of the hives make an unusual show of numbers.

3. I suppose you’d like to know why such difference. Well, there may be a difference in the industry of colonies. That one colony is in a more exposed position, and that the other is near some protected place, and there is a maple patch or the brood-nest may also make a difference. One colony had an old queen which did not lay well, and instead of keeping its combs filled with brood in June filled them chiefly with honey. Then it superseded its queen, rearing a young and vigorous one which not only filled all the vacant cells with eggs, giving no chance for storing below, but obliged the bees to carry up some of the honey previously stored in the brood-combs. A few years ago we had a change in weather during the first part of the season, allowing very little honey to be stored in the brood-nest. As the season advanced the queen was forced to lay in, and the vacant cells left by the hatching bees were largely filled with honey, leaving the honey-board to be covered by holding the bees up, or by putting a brood-board in place of the honey-board, having nothing whatever between the top-bars and the super above. You will probably be pleased if you
make such a change; but you must allow only ½ inch or a shade less between the top-bars and the sections or frames in the super. It will also be a help to have only ½ inch space between each top-bar, space you can secure by nailing strips of light wood of the appropriate size to the sides of your super in the exact top and bottom, and keepers also think it desirable that the top-bars be from ¾ to ½ inch thick or deep.

5. By having the space between top-bars and a super a scant quarter of an inch. You can also prevent it by doing away with honey-boards altogether.

6. Letting air directly into the super has the effect to make slower work in building comb wherever the air enters. So look for comb honey, but is a good thing for extracted honey.

7. They are of such universal adaptation that almost certainly they will succeed with you. You may sow in fall or spring. They will grow the first year without blossoming; the second year, they will begin blooming before white clover is over, and not stop entirely till hard freezing weather; and the following winter they will die root and branch.

**The Afterthought.**

The "Old Reliable" seen through New and Unreliable Glasses.

By E. E. HASTY, Stix. B. Roral, Toledo, O.

**The Home Circle.**

Conducted by Prof. A. J. Cook, Claremont, Cali.

**CORONADO.**

There are three places that every visitor of Southern California should certainly see before he leaves this part of our country. I hardly need to say that one of these is Redlands, with her incomparable "Smiley Heights," wealth of verdure, beautiful homes, and show of thrill everywhere. That one is Santa Barbara, with its lovely bay, its splendid climate, magnificent mountains and sea, and its incomparable suburb, beautiful Montecito. I have just spent Sunday at the third, beautiful Coronado. This is across the bay from San Diego. The climate here is wondrous even for California; never hot in summer, never cold in winter. San Diego and Coronado enjoy and rejoice in one perpetual summer.

Off San Diego are two long peninsulas. The outer, Point Loma, stretches southward, is some miles long, and high and precipitous. The inner, Coronado, stretches northward more miles, is often very narrow, and is low and level. All of Point Loma holds the ocean from the beautiful Harbor of San Diego. Only the south end of Coronado feels the pulse-beats of the great Pacific. Coronado Hotel, and Coronado Tent City, mark the limit where the ocean sweeps this peninsula. So it is opposite the point of Loma. On one side the huge breakers thunder along the shore; on the other the long, quiet bay nestles, and is in striking contrast to the rough seas. That is the very narrow stretch of land. The great ocean steamers, or the more powerful war vessels that are wont to enter San Diego Harbor, must round the magnificent Point Loma, then pass northward in the narrow channel between the Coronado peninsulas, then round the extreme northerly point of Coronado, when they may drop anchor in the ever peaceful waters of San Diego Harbor.

Coronado Hotel is one of the grandest in the world. Its prices are equally renowned, yet the moderate price may still be had. The food is wondrous. The cuisine is rarest edification. The same company that controls the great and far-famed hotel, are likewise proprietors of Tent City, where neat-dressed and carpeted tents can be rented very reasonably. A fine tent for three can be had for a month. In this are good beds, all the utensils for light housekeeping, gasoline stove, dishes, table, etc. Table and bed linen are also furnished. A good and very reasonable restaurant may be made to supplement

Sealing inside, directly on the hot honey, looks rather like a novelty. Pages 564—566.

**PRODOLING SECTION-TOPS.**

Dr. Miller’s third answer to Indiana’s questions will bear talking about. He is doubtless correct that bees often dand the top of sections worse when an enameled cloth is laid on. Angles with a crevice in the bottom of the angle always will have some objection made to them, but are awful busy at something more important. In doing this job they ram the material home forcibly, with the result that the section tops are soldered quite a distance from the edge. There is another side to the question, however.

**The "ONENESS" OF CLAREMONT.**

Happy Claremont! One church, one literary club, one horticultural society! I don’t know but such a town ought to pray never to grow any bigger. I’m sure they have a right to pray a little. "Lord, we thank thee that we are not in the spirit of split-up-eness as other towns are." Page 569.

**BRITISH COLUMBIA BEE-KEEPING.**

And so in British Columbia one man says bees can not find supplies—has tried it—and another man gets 90 pounds of sections. Page 571.

**HONEY AND HONEY CONSUMERS.**

And so black mangrove honey from Florida, notwithstanding its high quality and flavor, stirred up suspicion when peddled in a distant State where no one ever tasted just such a taste. Apparently Mr. Wallemeyer has struck an important general principle. The ordinary customer wants one of the honeys he has tasted before—and fears a swallow.

But it isn’t a general principle everywhere that consumers object to buying as much as three pounds of one thing within delivery distance of a city grocery does seem to stimulate the disposition to buy by dribbles, but the main cause lies elsewhere. Most consumers consider buying honey at all as a piece of extravagance. They dash in desperately to the depth of half a pound; but would consider it wicked to go much deeper. The remedies are obvious, if we are willing to use them. In retailing extracted honey I use a five pound package, and am seldom asked for less. If I remember rightly, we breeders sell almost entirely in a 20-

"Useful when empty" is a very important phrase.

Shot in every new bottle to break out the shelby, thin glass. Sugar.

Could wish that all the pictures had turned out clear like the first one, so that we might learn the exact manipulation.

Good wife that will non-colloquially get dinner with 300 pounds of honey encumbering the range!1

No sin to adulterate with paraffine your own usings of wax, if it makes it better.

Oct. 17, 1901.

AMERICAN BEE JOURNAL

665
the home fare if one desires. A good literary and reading-room, with all the papers and magazines, is free to all. A very fine band discourses most beautiful music each evening. All kinds of bathing—surf, still water, or indoor warm water plunge bathing are at the command of all. All the attractions of the great hotel are shared with the occupants of Tent City. For one of my simple tastes Tent City offers as inviting a menu as does the great hotel. I know of no place in California, or elsewhere, where as much can be had to gratify wholesome desire as at this beautiful retreat at delightful Coronado.

CULTURE.

At the pretty little hamlet of Chula Vista, on the mainland opposite the south end of Coronado peninsula, I had the pleasure of being entertained by Judge A. Haines for two days the past week. At the dinner table one evening, Judge Haines, who has a family of delightful and promising children, two of whom are making an enviable record in college, remarked upon the tremendous importance of the parents gaining and holding the fullest confidence and sympathy of the children. To do this we parents MUST be able to enter fully into the plans, thoughts and feelings of our children; must give heartiest sympathy to all that pleases and interests them. This, said the Judge, is the key to all right training in the home.

I was greatly interested in his further remark, that the best use of education was to make us able to extend these sympathies. Nothing, said the Judge, will help us so much to give and gain this fullest and best sympathy, as will rich culture. Thus education, broadest and best, will, as its best fruit, make possible such training as will result in grandest men and women. Such will most exalt our citizenship, and most bless the world. Judge and Mrs. Haines' own home and family are the best proofs that his philosophy is correct.

The Judge made one other remark: Anarchy, whose foul presence has struck such a cruel blow not only at us, but the world, feeds on sensation and superstition. Culture is the arch foe to both these blots of character. Culture, then, should rid us of theastardly presence, that so seriously menaces our peace and safety.

EVERGREEN TREES.

The mother-love is one of the most holy and sacred of instincts. It impels the mother-bird to fashion her nest where the younglings will be most secure against discovery and harm. Thus the pine and other evergreens are most sought for purposes of nest-building. Thus every home grounds we may well plant a group of evergreens. I have only two lots for my home at Claremont, yet down by the barn I have a vigorous Monterey pine, Lawson cypress, Norway spruce, silver cedar, giant sequoia, and graceful arbor vitae. Already the birds have found my grove and appreciated it for nest-building. Thus this grove has three advantages: It gives real beauty, gives a touch of evergreen landscape, brings the cheering, beautiful presence of our feathered friends. Hurrah for the little grove of ever verdant conifers!

THE GARDEN.

Every bee-keeper, every rancher, should have a garden. What a superb place to give the children the needed wholesome employment! What a chance to give them responsibility and opportunity to earn money that shall be all their own! What a rich addition it gives to the family table as the best corn and peas are only known to him who raises them in his own well-cared-for garden. What a rich pleasure for the family as a whole, to plan, plant and clean in this little best corner of the home grounds. With what pride we note the growth of the luxurious pie plant and vigorous asparagus. A friend—a very busy man of Escondido—a great bee-section, has just told me how he helps the purse by his garden. He has only three lots, all told, yet his monthly income is very helpful. One month it reached $20.80. His cabbages sold readily for two cents per pound, when lemons sold for only one cent.

20 HENS working together at one time can not hatch so many chickens as one of our 280000 size Successful Incubators. You'll know exactly why when you read a copy of our free leaflet. We have different sizes.

Please mention Bee Journal when writing.

A FRIEND to poultrymen—folechickens. Adam's Bone Cutter. It runs easily because it has ball bearings. It cuts cleanly, quickly and perfectly. Makes a fine bone shaving such as chickens require. DESKS FOR GENTLEMEN AND LADIES!

These DESKS are made of quarter-sawn oak, first-class finish, well put together, and will please every purchaser. They are an ornament to any home, as well as being a useful necessity. Would make a FINE GIFT for father, mother or sister.

The Combination Desk and Book-Case is just the thing for a farmer or business man of any kind, to keep his private papers in, and for his books, etc. The drawers have locks, and there are a number of pigeon-holes inside each of the desks shown herewith.

The low prices quoted are f.o.b. Chicago. Send for free catalog. Address, The Royal Star Combination Game-Board Co., 773 to 779 Carroll Ave., CHICAGO, ILL.

Ladies' Desk. Price, $8.25.
REVERSIBLE WALL MAP
OF THE
UNITED STATES AND WORLD,
WITH SPECIAL INSET MAPS OF
China, Cuba, Porto Rico, The Philippines, Hawaii, and Alaska,
Especially prepared to meet the demand for a first-class map that will give a quick, general idea of location of events the world over, and particularly to the United States and our territorial possessions. Very useful in every Home and Office. 66 X 46 INCHES IN SIZE.

ELEVEN BEAUTIFUL COLORS.

Best and Most Necessary Map Ever Issued.

The Plates are works of art. The engraving is plain, bold, and decisive. The color work is elegantly contrasted, but not gaudy.

Perfection and Artistic Elegance
a salient feature of this map not approached by any similar publication.

It has been pronounced a Photograph of the World.

The 1900 Census of the largest American Cities is given.

The 1901 EDITION—Every reader should consult it every day.

Marginal Index
is one of the invaluable features.

It gives an alphabetical list of countries, their location on map, style of government, population, area, products, minerals, imports, exports, etc.

A special accession to the 1901 edition is the Index of the 1900 Census, which is an alphabetical list of the largest American cities.

On the reverse side is the Library Map of the World. The largest and most accurate map on Mercator's Projection ever produced. The political divisions are correctly defined and beautifully outlined in colors. The ocean currents are clearly shown and named. Ocean steamship lines with distances between important ports are given. A marginal index of letters and figures enables one easily to locate every country in the world. A series of short articles in alphabetical order is printed around the border of this map in large, clear type, containing valuable information concerning agricultural, mining, and manufacturing statistics, also the value of imports and exports in dollars. The area, population, form of government, and chief executive of every country in the world is given up to date, also the names of the capitals and their population. The Inset Maps are excellently engraved and printed in colors. They are placed in convenient positions around the United States map, and will be invaluable to every person desiring a plain understanding of our possessions. An inset map of China on the World side of map adds to its value.

Two maps on one sheet, all for only $1.50, sent by mail or prepaid express; or we will forward it free as a premium for sending us Three New Subscribers at $1.00 each; or for $2.00 we will send the Map and the American Bee Journal for one year.

Address,

GEORGE W. YORK & CO., 144 & 146 Erie Street, CHICAGO, ILL.
The Drone’s Folks.

"The drone," says a Straw in Gleanings in Bee-Culture, "is always a half orphan, for his father is always dead before he is born. He has no home, for the memory of his mother’s female children is never his father. In fact, he never has any father except his grandmother, and he never likes to see any of his children."

In Breeding.

The worst dangers in bee-keeping are where two beings are mated that are of exactly the same blood, having the same father and mother. Fortunately, the bee-keeper need take no pains to avoid such close breeding; Nature takes care of that. A drone and a queen from the same mother are not full brother and sister, and therefore the drone is not father of the drone. The only way to mate two of exactly the same blood is to mate a drone to his mother, and the drone is born too late for that.—Gleanings in Bee-Culture.

Bees and Pear-Blight.

Regarding the bee and pear-blight question in connection with the fall in the market for the blighted fruit, it is noticeable that many of the fruit-growers are coming to (or appearing to come to) the conclusion that there are certain means of protecting the blighted fruit, and that by following the same the trees in blossom will not materially abate the destructive effects of the pest. The same is true of the attention passed by the bee-keepers in their conception, to move the bees out of the region of the blighted trees during the time they were in blossom, required some raffity action on the part of the fruit-men in filling out certain blanks required by the drying merchants, and this was done some time ago, but nothing has been done. It is probably true that the pear-orchardists are not so sagacious as to the beneficial effects of the proposed removal, and many of them are fair men, and therefore disinclined to put the bee-keepers to this expense unnecessarily.

I talked with Prof. Weihrauch (who, it will be remembered, originally declared the bees to be guilty), while in Buffalo, regarding this case of the pear-blight, and he was not inclined that the bees would bring about relief, owing to the presence of wild bees and numerous other insects that would, undoubtedly, spread the disease. He was sure, from extended experiments, that the bees were very necessary for the health and proper maturing of the fruit, although he admitted that possibly conditions in California might be different. Pear culture is a careful, canny man, and a friend of the bees, and so much so that he deems it necessary to have a few colonies of them in his own pear-orchard, pear-blight or no pear-blight.

Taking everything into consideration, it appears now there will be no conflicting of interests between the bee-keepers and pear-men; and it is hoped that the matter will remain thus. It is probable that the pear-blight disease losses its hold or "runs out," as we sincerely hope it may,—Gleanings in Bee-Culture.

"Review Notes" from the Bee-Keepers’ Review.

Beeswax is the last thing that I should think of using for a lubricant, yet when I took my spectacles to a jeweler because one of the hinges was badly out of order, I was told that it was difficult to move it, he simply rubbed beeswax around the joint and held it over a lamp until it was hot, then he put it on, and there it has worked all right. He says that when the hinges to a watch-case work hard for some reason, rub beeswax on it if a similar thing occurs.

Extracting-Combs are better when they are thicker than the ordinary brood-combs. There is less caps for the bees to do, and less unapplying for the bee-keeper.—Besides, it is easier to uncap a thick than a thin comb.

Dittmer’s Foundation!

Retail—Wholesale—Jobbing.

I use a PROCESS that PRODUCES EVERY EXCEEDINGLY EASY and MOST desirable to all respects. My PROCESSES and AUTOMATIC MACHINERY are my own inventions, which enable me to SELL FOUNDATION and Work Wax Into Foundation For Cash at prices that are the lowest. Queen-Clipping Device Free.

The Monette Queen-Clipping Device is a fine thing for use in catching and clipping Queen-wings. We mail it for 25c; or with monette a minimum for sending as ONE NEW subscriber to the Bee Journal for one year at $1.00 per year. We will mail the Bee Journal one year and the Clipping Device Free.

GEO. W. YORK & COMPANY.

Chicago, Ill.

THE NICKEL PLATE ROAD will sell tickets each Tuesday, Thursday, and Saturday during October to Buffalo Pan-American Exposition and return, at $6.00, good in coaches, return limit 3 days from date of sale. Tickets with longer limit at slightly increased rates. Three trains daily. Chicago Passenger Station, Van Buren St. and Pacific Avenue. City ticket office, 111 Adams St., Chicago.

With thick combs there are fewer to handle. No beekeepers produce bees better or more easily than the bee-keeper in the brood-nest. With the Heddon hive Mr. J. B. Hall, of Ontario, uses only comb in a single packet thin strips of wood to the edges of the honey, the frames of such a width that seven will place in the brood-nest. If the frames are needed for brood-rearing this is an easy matter to remove the strips of wood.

Packing put around the bees in winter sometimes causes confusion, for their movements will easily be detected by the radiates from the cluster. How it does this is well illustrated by the house that Mr. Jacob Alpaugh, of Ontario, told me of an experience of his when the season was an entire failure and colonies not able to hold through the winter. Although already in debt, he went in still deeper by getting several hundred dollars worth of vegetables. The next year proved to be one of the best. Prices were good, and there were only a few bees in the Parmatine, and this he put in then and left with money in his pocket.

A STRUT STRING, or even a piece of wire, attached to the end of the tree, is an efficient device for starting a screw-cap on a honey-can, or loosening the cover of a fruit-case. I find the string wound around the cover, drawn up, drawn down, or drawn out by the string will not slip, and then use the stick as a lever for starting it. But had you ever thought of it? I saw this device at the house of R. H. Smith, of Ontario.

EQUALIZING COLONIES and contracting the brood-nests of old colonies just at the opening of the honey harvest is something that is not often practiced, but Mr. Albert E. Hall, of Ontario, says that with the Heddon hive he finds it an advantage. He looks over both cases of both-nests, and if it is necessary to equalize colonies that contain the most brood, leaving this case upon the comb. The combs of honey are left away to be given to the bees. At the time the harvest is over. The more populous colonies will contain more than one case of brood, while the weaker colonies have less than one case of brood; and, by the time each colony is given one full case of brood, not much of any brood will be left. This methodcrowds the bees into the sections and curtails the production of beeess at just about that time.

PREGNANT QUEENS are something that may be found in the apiaries of Mr. Miller, of the last one having a record of each colony, the breeding of the queen, the amount of surplus secured, etc. to this colony, this year, next year, and a list, furnished seven super of surplus. He hasn’t looked up the breeding of the queen yet, but says he can trace its back ten years.

Bee-keeping Colonies devoted to comb honey production, and the others to extracted honey, will allow the bee-keeper to require their a year from his honey, the bees worked for comb honey will swarm, and thus furnish the queen-cells for use in the comb. This was said by A. E. Hoshall, of Ontario.

CUSHIONS are usually used on top of colonies that are wintered out-of-doors, but M. H. Hunt says that he prefers to lay a large piece to make hay, the Sharples Drum Separators. Look "Business Directory" & Cat. 212 free. W. Chester, Pa.
of cloth in the upper story, over the broad-
est, and pour the chaff into the cloth. He says that he has stuck more stringently than the corners, than with the cushions. In the spring he can grasp the cloth by the corners, lift it out, and dump its contents into a box. The cloth is packed away in a small space for the summer, and are easily protected from the ravages of the weather.

A PORTICO, four or five inches deep, having a wire-cloth front, and large enough to cover the whole front of the hive, is the best thing possible with which to fasten in bees when moving them or shipping them. Nothing worries bees more, or sooner puts them into a ferment, than to find the entrance closed. While such a portico does not allow the bees to fly, it does not close the entrance, and allows them to live in it, off the comb. When hives are arranged in this way they can be stacked up without shutting off the ventilation. Jacob Almagn, of Oregon, has some porticos as these for use in moving bees, and one of them can be fastened to the front of the hive in about five seconds by means of a hook made of wire. He had two colonies swarm once when moving, and the porticos were filled so full of exciting bees that the latter disgorged the honey in their sacs and perished as a result.

DRAWS COMBS in sections can be very profitably secured by the close of the beard, and wood by leaving on one super of finished sections, raising it up and putting beneath it a case of sections filled with foundation. By keeping close watch this can be removed as soon as the combs are partly drawn, and before much honey has been stored in them, or the sections are scarcely soiled with propolis. If the flow continues longer, another case of sections can be put in the place of the one removed, and another set of drawn combs secured. Such super of half-drawn combs are very valuable for use the next spring.

HIVES IN GROUPS of four is the arrangement used in the apiary of J. B. Hall, of Ontario. The groups are named from the letters of the alphabet; thus there is A group, B group, and so on. The two north hives in group A face north, the two south ones face south. In group B the two west ones face west, the two east ones face east. In group C the hives face north and south the same as in group A. By this arrangement no two hives standing near each other have the same relative position, and there is little danger of a returning swarm getting into the wrong hive. When the bees are placed in the cellar in the fall, each hive is marked with a pencil on the front in such a way as to indicate its position: thus: "G—S—W" means that it is the southwest hive in group G. In order that the position of group G may not be forgotten, a big letter G is printed on a piece of section-box, and taken to a tree just north of the group. Other groups are marked in a similar manner.

Standard Belgian Hare Book!

BY M. D. CAPP.

THIS book of 175 pages presents a clear and concise treatment of the Bel-
gian Hare industry: Its growth, origin and kinds; the san-
titation and constructing of the hares; the selection of breeding stock; care for the young, feeding, dis-
ees and their diseases; marking, marketing, shipping, &c. The first edition sold 40,000 copies was sold in advance of publication.

Price, in handsome paper cover, 25 cents, post-
paid, with the American Bee Journal one year—both for only $1.10.

Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the Basswood, a strong, rich, laden basswood blossoms. It has a stronger flavor than Alfalfa, and is pre-
ferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:
A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 8 cents per pound; four or more cans, 75 cents per pound. Basswood Honey, 50 cents more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are boxed. This is all.

ABSOLUTELY PURE HONEY

The finest of their kinds produced in this country.

Read Dr. Miller's Testimony on Alfalfa Honey:
I've just sampled the honey you sent, and it's prime. Thank you. I feel that I'm something of a heretic, to sell several thousand pounds of honey of my own production and then buy honey of you for my own use. But I have to confess that for use in any kind of hot drink, where one prefers the more wholesome honey to sugar, the very excellence of the alfalfa honey I have received from you is better suited than the honey of more mild flavor, according to my taste.

C. C. MILLER.
Mclaren Co., Ill.

Order the Above Honey and then Sell It.
We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.
The New vs. the Old.

I started in the spring with 47 colonies, 6 of them too weak to give any color; I increased them, but I have doubled back to 70, and taken off 3800 pounds of honey, mostly extracted, and plenty of stores left for winter. The above has been done where bees in five box-gums could not exist together for want of flowers. I give the improved hive and the Italian bee credit for the above.

L. W. McRae.

Washoe Co., Ala., Oct. 2.

Honey Conditions in Nevada.

The Nevada State Journal (Washoe County's leading paper), says: "Nevada's honey crop is almost a failure. Around here the bee-men are telling the same story.

Such is the fact, all things considered. I have received 200 pounds per colony, and for the season I think I have taken the prize in this locality. I know of some who have received 300 pounds per colony; others have secured none at all. Although honey is scarce, buyers are offering only 1 cent per pound for comb, and 5 cents per pound for extracted. The A. I. Root Co. have a man in the field that is offering the best price: 50 cents per pound for comb, and 5 cents per pound for extracted. No sales have been made as yet, as we are after higher prices, if possible.

Slow Honey-Dealers.

I shipped to B. Presley & Co., St. Paul, Minn., on July 31, 1901, 675 pounds of as nice white honey as was ever put into cases, and for two months I could not get a word from them—not even an acknowledgement of the receipt of the 675 pounds. Finally, after getting an attorney to write them, they sent me the sum of $86.00, or a trifle over 10 cents per pound.

Kanabee Co., Minn., Oct. 5.

Good Season for Honey.

This has been a fairly prosperous year, notwithstanding the extended drought. The wild bees during the summer were flying free from storms and wind, thus giving an unequal number of working days. We had a heavy run early in the season, but cutting out little clover, also red clover, being used by the drouth, was visited more frequently than country by the bees, and we also had a fairly good fall flow from heartsease, goldenrod, and many other flowers that secrete only during dry, hot weather.

My surplus at home is 497 pounds to the colony, spring count, from 75 colonies: one colony, 15 pounds; another, 28; and the latter part of May I had a chance to sell 500 colonies for $2500, but during the negotiations the bees had flown away, and I refused to sell. I produce section honey, extracted, and chunk honey, and sell all of it without regard to color for 15 cents per pound, and look forward to local dealers in this and adjoining towns.

I am engaged in quite a number of other enterprises, but the connection with bees. Many neighboring farmers, who own their own farms, valued at $800 to $1400 each, and many of them seeing my annual profits do not exceed $800, while my average profits from sales of honey and bees from my home apiary have been for 10 years $300 per annum on the investment.

I am one who believes bee pay, and pay better than almost any other kind of business. I am in the business because it is profitable financially, and not for health or pleasure. I think an industrious person who would ordinarily succeed in other affairs will do so in keeping bees, but it is a hard job when we fail at farming or mercantile business I would not advise to go into the bee-business.

L. Gandy.

Richardson Co., Neb., Oct. 3.

An "Infallible" Method of Introducing Queens.

Bees are subject to more modes of manipulation than any other creature we have. There are all kinds and shapes of hives, all sizes of frames and sections, differences of foundation, and methods of introducing queens, all of which go to "rattle" the amateur, and place him in a helpless position. A wise bee-keeper has the only one." B says, "My way of manipulat-

ing bees is the best way;" and now here I am saying that this way of introducing queens as infallible. Yes, infallible only in colonies where a laying queen has been taken out within a very few days, say not to exceed four, and there is lots of hatching brood, and this may be done just as soon as the old queen is removed. When you have found the old queen, and killed her or disposed of her in some other way to suit your convenience, every bee out of one hive is mounted on a new queen, and lift a frame from the hive and put into the cage, 15, to 20 young bees from one hive. I have been told that doubtfully there are no old bees put into the cage. Remove the top cover, and, in from 24 to 48 hours the queen will be hiber-

nating, laying her eggs in the cells within six hours.

Queens are very nervous little things, and when the cage is filled up with the little innocent, fuzzy things, she is contented, and the colony at once will say, "Look at the young queen; why, the cage is full of our bees;" and they do not molest her. "So we will hustle her out," and surely they will, and even when she seems to be a bit nervous, her nervousness has all disappeared, and she takes up her duties and commences laying in a very short time. I have been told to cut her out now and introduce them in this way. This may not be my own invention, yet I have never seen it mentioned, but possibly it has been; but some amateur may profit by it, nevertheless. A. D. D. Wood.

Poor-Season—Old Bee-Books, Etc.

I am a new scholar in bee-keeping, I bought two colonies last fall; one swarmed, and I captured it. The season was poor, and I found it difficult to carry them through. I did not get a taste of honey. Although my first attempt is a failure I will continue; that is my ambition, and I have looked into the affairs of the National Bee-Keepers' Association.

I have been deeply impressed by the high character. Christian spirit and police shown, each to the other, at the bee-keepers' conventions and rallies. I would have enjoyed meeting the brethren (and sisters, too) at Buffalo, and receiving advice and pointers (though I have received some pointed ones from the books).

I love to read the American Bee Journal so much that I feel lost when I do not have it in my hand.

I have just read three old books on bee-keeping—one by Mosey Rusden, July 14, 1869, dedicated to the "King's Most Excellent Majesty." This book is in four sections, has 143 pages, gives very clear the habits, nature, and functions, of the "king-bee," tells how to handle bees (up-to-date, 1869!) how to construct hives, treats on diseases of bees, and, in short, does everything. If any man knows anything more than I impart, let him disclose it; otherwise, improve with me.

The next book is by Thomas Widman, 1770, "A Treatise on the Management of Bees." His writing is delightful and very palatable to peruse. He describes a movable-frame hive (quite up-to-date). The engravers are almost as good as any of the older writers. I wish you could read this book for its many interesting points.
SWEET CLOVER
And Several Other Clover Seeds.

SWEET CLOVER

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Oct. 10.—There is a very good trade in No. 1 comb honey at $4.50 per lb.; that which is well packed at $4.75 to $5 per lb., from $3.75 to $4.25 per lb., from $1.36 to $1.44 per lb.; some small lots of fancy have come on the market this week, the prices for these being from $1.36 to $1.44 per lb.; the dark honeys of various grades range at from $1.06 to $1.16. Extracted sells fairly well, from 25 to 27 cents per lb. for white and dark honeys. White clover honey is at 25. A. R. BERNETT & CO.

CINCINNATI, Aug. 10.—The honey market is rather dull on account of the warm weather. Extracted sells very free at 25 to 26 cents per lb. for white and dark honeys. Better grades alfalfa water-white from 36 to 38 cents; white clover from 38 to 40 cents. Fancy white comb honey sells at from 135 to 136 cents.

C. W. WEBER.

BOSTON, Oct. 12.—Fancy 1-pound honey in cartons, $1.70; A No. 1 in glass or cartons, 15c; No. 1, $1.15; very little No. 2 being received. Light amber extracted, 75.

BLAIRS, SCOTT & LEE.

ALBANY, N. Y., Sept. 19.—We quote: Fancy white comb, $1.25; No. 1, 135c; No. 1, $1.15; No. 2, 85c; No. 3, 60c. Extracted, white, 75é; light amber, 65 to 67c; dark, 55 to 60c. Beeex., 28c to 30c.

H. W. RICHARDSON.

OMAHA, Aug. 8.—New comb honey is arriving by express and is selling well in this city, and Colorado, and selling at $2.50 per case in a retail way. California black clover honey is offered in carlots at 42¢ to 44c per pound, f.o.b. California shipping-points; but we have not heard of any being having in stock. The production of extracted honey seems to be quite large this year in Colorado, Utah and California.

PICKREY BROS.

NEW YORK, Sept. 12.—Comb honey is now beginning to arrive in large quantities, and, as a rule, the quality is very good, and the prices we quote as follows: Fancy white, 140c; No. 1, 115c; No. 2, 105c; No. 3, 95c. Extracted honey, 50c. Honey of this quality is in demand and in line before Sept. 1st. Our market does not consume a great deal of extracted honey.

PICKREY BROS.

DETROIT, Aug. 12.—Fancy white comb honey, 140c; No. 1, 130c; no dark to quote. Extracted, white, 55c; light amber, 55c; dark, 45c. Beeex., 26c to 28c.

Arrivals and spot offerings of this moderate volume, but there is as much or more market than can be conveniently or advantageously placed. To secure liberal wholesale custom, prices would have to be shaded in favor of buyers. A large and abundant market for our comb and extractable honeys are expected. Other desirable lots slightly higher figures than are quoted are realized.

KANSAS CITY, Sept. 14.—Up to the present time only small lots of new comb honey have been on the market, and these met with ready sale. The sales of boxed clover honey have been slow, although the price is $4.25 per lb. for fancy white. For next week heavier receipts are expected and quotations are named at $1.06 to $1.25 per lb. for fancy. A few small lots of clover honey ranging from about 140c to 145c; the demand being quite brisk, a few lots are at a premium. A large and ready market for comb and extracted are a little more numerous, but large bayers still want to have their ideals too low. In a small way 56c is establishment.

PICKREY BROS.
We have a Large Stock on hand and can ship promptly.

SEND US YOUR ORDERS OR ANYTHING YOU WANT THE BEE-KEEPING LINE.

WE MAKE ONLY THE BEST.

Our Falcon Sections and New Process Foundation are ahead of everything, and cost no more than other makers. New Catalog and copy of KEEP FREE. Address, THE W. T. FALGONER MFG. CO., JAMESTOWN, N. Y.

A New Bee-Keeper’s Song—

“Buckwheat Cakes and Honey”

Words by EUGENE SECOR, Music by GEORGE W. YORK.

This song was written specially for the Buffalo convention, and was sung there. It is written for organ or piano, and has been all the songs written for bee-keepers. Every home should have a copy of it, as well as a copy of

“THE HUM OF THE BEES in the APPLE-TREE BLOOM”

Written by EUGENE SECOR and Dr. C. C. MILLER.

Prices—Either song will be mailed for 10 cents (stamps or silver), or both for only 15 cents. Or, for $1.00 strictly in advance payment of a year’s subscription to the American Bee Journal, we will mail both of these songs free, if asked for.

RED CLOVER QUEENS

BLACK ROCK, N. Y., Sept. 3, 1901.

FRIEND ERNEST:—I will try and tell you what you want to know about that queen. I got her of you in 1897 as a premium with GLEANINGS. I never saw a small colony of bees build up as that one did. In the spring of 1900 they came out in fine shape, wintered perfect. I raised them up in May and gave them 8 frames more so the queen would not want for room. I never saw such a colony of bees as they were in June, and they were actually storing honey when other bees in my yard were starving. No! They were not robbing. I never saw those two best colonies of mine trying to rob. THEY CERTAINLY WORK ON RED CLOVER. This is no guesswork, as I have seen them. As you know, the past two seasons have been very poor, and what honey my bees did get in 1900 canned soon after cold weather set in. I packed this colony in a chaff hive and left them out, thinking that such a strong colony would winter perfect. The snow came on the middle of November, and those poor bees never a fly until the last of March or the first of April. When warm weather at last came I thought they were dead, as they did not seem to be flying much, so I did not pay any attention to them until in June. I noticed they were working a little, so I opened up the hive and found them in the upper story. I took the lower story out and left them in the one body. The queen was laying nicely, and I thought they would make a good colony to winter. At the last of July I noticed that they needed more room. I gave them super, 24 boxes, and in a few days they had it full. They have made 72 boxes of as nice honey as you ever saw, and are drawing out some starters now, Sept. 2. Very truly yours, GEO. B. HOWE.

Prices of Red Clover Queens.

| Gleanings in Bee-Culture | 1 year and Untested Queen | $2.00 |
| Test Queen | $4.00 |
| Select Tested Queen | $6.00 |

If you want something good you can not do better than to order one of these queens. All orders are filled promptly. No extra postage on these to foreign countries.

Langstroth on The Honey Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for $1.25, or club it with the American Bee Journal for one year—both for $1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with $3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

HOWARD M. MELBEE, HONEYVILLE, O.

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The holsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the liners are plated brass; the back springs of Sheffield spring-steel; and the finish of the handle as described above. It will last a fast time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it otherwise they will send the name and address, and destroy the knife. It traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your Pocket Knife will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How to apply this Knife. What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying car gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for $1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with $3.00). We will club the Novelty Knife and the Bee Journal for one year, both for $1.50.

Membership Dues, $1.00 a year.
“Too Prevalent” Unqueening.—Quite a number of beginners in bee-keeping make a big mistake in the first year. They have ordered or purchased queens from a dealer or breeder, they immediately kill the queens of the colonies where they wish to introduce the new queens when they arrive. This is a risky and unnecessary thing to do. Never destroy a queen as early as the queen sent for is received. Very often queens can not be sent by return mail, even if so advertised. A breeder may be able to send by return mail almost invariably, but more than likely the bee-keeper who has been so hasty as to kill the old queen before the new one arrives is so unfortunate as to have the mailing of his queen unavoidably delayed several days or a week. Even a queen-breeder can not control all circumstances at all times. So the safest way is to wait until the new queen is on hand, then proceed to remove the old queen and introduce the new one according to directions.

Discrepancies of Apriarian Writers.—There is not entire unanimity among the writers of bee-literature. Views are held that seem diametrically opposed. Sometimes they are really just as much opposed as they seem to be. Sometimes wrong views are held. Sometimes a difference of locality or a difference in conditions may give rise to opposite views, both views being right. Sometimes, however, a fuller understanding may show that there is really no discrepancy where discrepancy appeared.

A case in point is that of getting unfinished sections cleared out by the bees. The Miller plan is to have the sections in a pile with an entrance so small that only one or two bees can pass at a time. The B. Taylor plan is to spread out the sections so as to allow the freest approach. One plan seems to be the exact opposite of the other, yet a little explanation will show that both plans have the same basis for action.

In a time of scarcity expose a single section of honey, and in a little while it will be so thickly covered with bees that no part of the comb can be seen, and the comb will be chewed up by little bits. If by any means it can be so managed that the bees shall not beat all crowded upon the comb, the bees will deliberately empty the honey without marring the comb.

The Miller plan says: Admit so few bees at a time that they will not be crowded upon the comb. The Taylor plan says: Spread out so many sections that there will be no crowding. Each plan strives for the same thing—to prevent the bees crowding upon the comb. The Miller plan is safe in any case; the Taylor plan works more rapidly, but can be used only when 8 or 10 sections can be put out for each colony.

The Illinois Fair Premiums were awarded by C. A. Dumont this year. Secretary James A. Stone, of the State Bee-Keepers’ Association, has sent us the list, which is as follows:

- Display of comb honey—1st, J. A. Stone & Son, $30; 2d, Chas. Becker, $15; 3d, G. M. Rumler, $10.
- Collection labeled cases containing 12 or more pounds of white honey from different flowers—1st, Chas. Becker, $8; 2d, J. A. Stone & Son, $5; G. M. Rumler, $5.
- Collection labeled cases containing 12 or more pounds of amber or dark honey from different flowers—1st, Chas. Becker, $5; 2d, G. M. Rumler, $5.
- Case white clover honey, 12 to 24 pounds—Geo. A. Hunt, $3; J. A. Stone & Son, $5.
- Case of sweet clover honey, 12 to 24 pounds—J. A. Stone & Son, $5; Aaron Coppin, $2.
- Case of basswood honey, 12 to 24 pounds—Chas. Becker, $4; J. A. Stone & Son, $5; G. M. Rumler, $5.
- Display of extracted honey—Chas. Becker, $20; 2d, J. A. Stone & Son, $15; 3d, G. M. Rumler, $10.
- Honey extracting on the grounds—Chas. Becker, $5; Aaron Coppin, $4; Geo. A. Hunt, $3; J. A. Stone & Son, $5.
- Frame of comb honey for extracting—Chas. Becker, $5; 2d, J. A. Stone & Son, $5; 3d, G. M. Rumler, $5.
- Display of candied honey—Chas. Becker, $3; 2d, J. A. Stone & Son, $5; 3d, G. M. Rumler, $5.
- Display of beeswax—Chas. Becker, $5; 2d, J. A. Stone & Son, $5; 3d, G. M. Rumler, $5.
- Honey vinegar, one-half gallon, with recipe for making—Chas. Becker, $4; 2d, J. A. Stone & Son, $5; 3d, G. M. Rumler, $5.
- Display of designs in honey or beeswax—J. A. Stone & Son, $12; 2d, Chas. Becker, $8; 3d, G. M. Rumler, $6.

The Colorado Convention.—The 22d annual session of the Colorado State Bee-Keepers’ Association will be held in Representatives Hall, State Capitol, Denver, Nov. 18, 19, and 20. The following program has been prepared by the program committee. The secretary, D. W. Working, says it is probable there will be a few minor changes in the program, but nearly all the papers have been definitely promised, and that a profitable and interesting meeting is assured.

In addition to the usual officers’ reports, discussions of questions, etc., the following papers, addresses, etc., will be given:
- Grading Honey—J. S. Bruce.
- Summary of the Recent Discussions on Brood—F. L. Thompson.
- President’s Address—R. C. Akin.
- Stereopticon Talk, Illustrating Bee-Keeping in the United States and Canada—E. R. Root.
- The Interests of Isolated Bee-Keepers—Frank Drexel.
- Advice to Beginners—H. C. Morehouse.
- Methods of Wintering Bees—F. L. Jouno.
- A Good Honey-House—T. Lytle.
- Abnormal Swarming-Fever—Mrs. A. J. Barber.
- How to Extract Honey—A. F. Foster.
- The National Bee-Keepers’ Association—R. C. Akin.

An attractive feature will be the exhibit of bees and bee-products. The premium list (a copy of which we have not seen) should attract a large and representative showing of the work of our little storers of sweets.

It is earnestly hoped that there may be a large attendance. The Colorado Association is practically the only rival of the National, both in membership and value to the bee-keeping industry of the United States. Some day we trust there may be others to claim such a distinction.

How Long are Brood-Combs Good?—To this question a bee-keeper replies in Centralblatt, that at the most they should not be used more than three or four years, one reason therefor being that the queen shows her preference for new combs in which the bees are better developed. It would be very hard to convince the mass of bee-keepers that just as well developed bees do not proceed from combs 20 years old. And that queens prefer to lay in fresh combs is decidedly against the observations of many bee-keepers on this side.

Correct Use of Bee-Keeping Terms is a matter of some consequence. It has been a matter of no little difficulty to have the use of “hive” for “colony” eliminated from our bee-literature. “Swarm” for “colony” was also quite common. Now that the tendency toward correctness in terms has become somewhat general, there seems to be a letting-up under the plea that several names for the same thing gives a pleasing variety. This is

Report of the Proceeding of the Thirty-Second Annual Convention of the National Bee-Keepers' Association, held at Buffalo, New York, Sept. 10, 11 and 12, 1901.

The 32d annual convention of the National Bee-Keepers' Association was called to order at 7:30 p.m., Sept. 10, by Pres. E. R. Root, of Ohio, who called on Rev. E. T. Abbott, of Missouri, to offer prayer. Mayor Diehl, of Buffalo, was then introduced to the convention and delivered the following Address of Welcome.

I don't know as the Mayor can entertain you very long, but I wish to extend to you a most hearty welcome to our city, and I am sure that your deliberations will be of benefit to your

The Buffalo Convention.

Report of the Proceeding of the Thirty-Second Annual Convention of the National Bee-Keepers' Association, held at Buffalo, New York, Sept. 10, 11 and 12, 1901.

The 32d annual convention of the National Bee-Keepers' Association was called to order at 7:30 p.m., Sept. 10, by Pres. E. R. Root, of Ohio, who called on Rev. E. T. Abbott, of Missouri, to offer prayer. Mayor Diehl, of Buffalo, was then introduced to the convention and delivered the following Address of Welcome.

I don't know as the Mayor can entertain you very long, but I wish to extend to you a most hearty welcome to our city, and I am sure that your deliberations will be of benefit to your

 himself has been of great benefit to the people of Alsace." And he took me into an addition to his barn and showed me a large tin tub and showed me how the Americans had taught him to get the honey out of the combs by the centripetal method, and it, of course, pleased me as an American citizen very much, and shows me that your meeting tonight must be of benefit to you and of benefit to everybody.

I hope that, in the interval between your deliberations, you may have an opportunity to see our beautiful Exposition, which will certainly show a large number of exhibits that will be of interest to you: and not alone the exhibits but the beauty, the advance ment, as to say, of civilization, in color schemes and everything that pertains to that; and, aside from that, I hope you will also, as time permits, see not alone the Exposition, but our beautiful city. I think we have the most beautiful city in the world; we certainly have as nice homes, more asphalt streets and the finest break water in the world; and the Government will certainly be enhanced by all the advantages we now have, and which our good Government has done for the city of Buffalo by placing that very extensive breakwater before our city gates.

In closing, I wish to inform you that, having just heard from the President's belfry, I think I safely tell you that the danger line has passed, and the President will get well. And now, extending to you all the courtesies of our city, and the freedom of our city, you will accept the same, so that when you return to your homes you may have a pleasant remembrance of our city.

Rev. E. T. Abbott, of Missouri, responded as follows to the Mayor's address:

Response to the Mayor's Address.

It is surely a source of exceedingly great pleasure to me to respond to such an address of welcome, on account of its significance. Bee-keeping has not always received the recognition that it should. I think that the Government, at the hands of the Governments of the cities where we have held our meetings, I have thought sometimes that the citizens of the city, and the freedom of the city, you will accept the same, so that when you return to your homes you may have a pleasant remembrance of our city.

AMERICAN BEE JOURNAL

Oct. 24, 1901.

during all of my experience in attending the meetings of the National Bee-Keepers’ Association, and I have attended all of them for a number of years. Now I would like to tell you a story that has been told by the Mayor of Buffalo, who is a member of the Bee-Keepers’ Association and who happens to be one of the best bee-keepers there are in America, and, notwithstanding the fact that America is in advance of Germany in bee-keeping, yet there is more enthusiasm in Germany than in America, and there are more Germans who have a clear and intelligent conception of farm bee-keeping than any other people. There are more Germans who are making it profitable in connection with other agriculture—for I look upon it as a branch of agriculture.

And now I am glad that the people of Buffalo have had the good sense to elect to this high office the gentleman who was so closely in touch with Mr. Parks and Mr. Parks, who are the keepers of the soil, from which all the wealth of the land, and out of which all the glory and beauty of this great city have been built. I say I am glad to know that the people of Buffalo have had the good sense to do a thing of that kind. It speaks well for the future of the country, for what is needed is to bring the country and the city in close touch with each other, to get the farmer to understand that he is not a "hayseed," to get the citizen of the great city to understand that all the brain doesn’t walk abroad on the great pavements; to get these facts, these two facts, clearly before the American people will be worth a great deal; when commerce and agriculture and trade come hand in hand with the man who holds the handle of the plow, when rural pursuits and city commerce move hand in hand and co-operate with each other, then will we have reached that I believe to be the ideal nation.

I am not surprised, of course, that the Mayor welcomes us to the city. We are a great people and deserve to be welcomed; we may be farmers and ordinary professionals, a great many of us, but we are the sweetest people on top of God’s earth. There isn’t any sweeter people that walk the earth, men and women both, than the bee-keepers; they deal in the sweetest, purest, healthiest, noblest sweet that the world has ever known. It is distilled by the chemistry created by the Almighty alone; it is drawn out of the vital energies of the universe. It is formed in a retort created by the hands of the Almighty and gathered by insects that has inhabited the world away back into geological ages, and stored away by them in a way that the skill of man and defies the most expert scientific man to imitate. It is true we are told that they manufacture comb honey out of clover; but that is not true. We add to the ignorant people of the city for the pure article, but we bee-people know that it is a newspaper canard. They do not do that. There isn’t any manufactured comb honey, but you will get in print to-morrow in big letters. But I tell you what they do: The unscrupulous city man takes a little bit of real good honey and puts a great deal of real dirty, stinking mean glucose into it, and puts it into a nice-looking bottle and labels it with a nicer-looking label, “Pure Clover Honey,” and sells it to the people who are green enough to buy it, and this has greatly injured our industry.

Now, to get back to my original proposition, that I was glad the city government was taking notice of us. Here is where the city government can greatly aid us, here is where the national government can aid us, when they come to our rescue and make it impossible for a man to sell anything for what it is not. Here is a work that the government of the city of Buffalo can take in hand and make it a criminal offense to sell a man a spoonful of honey and four spoonfuls of glucose all for honey. Anybody who wants four spoonfuls of glucose mixed with a spoonful of honey has a right to buy it, but call it what it is, a mixture, and let people use it as a mixture, but the bee-keepers protest against having it sold for honey, for it is not honey; it is a fraud, that is what we are afraid of.

Now, friends, I think I have said enough and have taken enough of your time. I think we all appreciate the words of welcome that have been extended to us, and I want to say to you, Mr. Mayor, that we will avail ourselves of them, we shall walk on your streets, we shall go out and see the great Pan-American, and, of course, this has been the greatest exposition of the kind that has ever been held, except one we shall hold in St. Louis, in 1903, the Louisiana Purchase Exposition. We wish Buffalo Godspeed, and all success, but we now, in behalf of the great, large-hearted people of the great State of Missouri, invite you to come and receive our welcome in that State of Jesse James, if you please, but of intelligence, progress and virtue, in 1903. We will have an exposition that will astonish not only the United States, but the world, for they are coming from all over the world, just as you have seen them. I thought Buffalo could never have an exposition like Chicago, but I want to say to Mr. York, who lives in Chicago, that when he gets out to the Pan-American he will see that the last is the best; and it looks now as if we were going to get just as many bee-keepers together as we have got in the past, and if so many of us, and the number, we may make up in enthusiasm for what we lack in numbers, and we will have the best North American Bee-Keepers’ Association to-day and in the history of this society. I thank you for your attention.

Dr. A. B. Mason, of Ohio—I notice here several Ontario Bee-Keepers’ Association badges, and I am so well pleased with it that I am going to move you that we give to all the members of the Ontario Bee-Keepers’ Association just the badges that are present with those badges on, the privileges of this floor, and to participate in all our discussions and answer questions, and to feel perfectly free and at home. I move you that we extend that privilege to them.

The motion was seconded by Dr. Abbott and carried.

Mr. John Newton, of Ontario, president of the Ontario Bee-Keepers’ Association—In behalf of our Association I would thank you for your kindness to us, and this invitation to take in the discussions the same as your own members. I am sure that we will be pleased to do so, and I know that we will feel at home, just as we tried to make your society at home when we had you in our midst.

Pres. Root—We have no set program. We are trying the experiment of having just a question-box, and it possibly may be a good thing. We have some men here who, we know, if they have a mind to, can make it a grand success. A good supply of questions has been handed to the secretary, Dr. Mason, and as we have no committee on question-box, he will read the first one.

Dr. C. C. Miller, of Illinois—I think it would be well to mention in connection with this matter that any member is entirely at liberty to hand in any question that he wants discussed.

AN APIARY OF CROSS BEES.

"Mr. Mason then read the first question, "What is to be done with an apiary of cross bees?"

Dr. Miller—I overheard a lady right here saying, "Kill them." If I had an entire apiary of cross bees I should want, first, to introduce some new blood of a kind that would be more gentle. This, however, is what will come in the experience of any beekeeper who has any number of colonies. We will find that these bees come from one or two colonies, and then all he needs to do is to kill one queen and introduce another queen; and a curious thing about that is, that a queen bee in the same apiary of bees has seemed to be much more rapid than the change in the blood of the bees; that is, if I find one such cross colony and kill the queen, I introduce another, within two weeks’ time, although there would be no change yet in the bees; that is, the same bees would be there; there would be a very decided change in their deportment, and although it seems rather unreasonable to suppose such a thing to be
the case, it looks to me as if the simple presence of the queen had something to do with the disposition of the bees.

Perhaps a further consideration for those who suggest the remedy. Sometimes bees are very cross in an apiary under certain kinds of management. Speaking abstractly, it seems to me that the cross bees I ever saw were the bees in southern California. It seemed to me that they were trained to be cross; I could not get anywhere near the frames but by profound secrecy, and sometimes if I was half a mile away they would come out to meet me. I fell to wondering why they were so cross. I missed the presence of the bee-keeper who keeps there extracted honey. Their hives are any old box, and they leave one or two inches of space between the extracting and the brood frames. When they separate the upper story from the lower one and get ready to extract they break all this comb, and it irritates the bees. The bees are what we would call a very good grade of hybrids, and they are not naturally very cross bees, but tearing the combs to pieces is apt to irritate them or worse.

A. A. Kluck, of Illinois—I have had a little experience with cross bees. In working around them, should they get cross, I would give them a little box that I could not get, then kick the hives. I whip my bees when they are cross, and smoke them till they don’t know anything.

W. L. Cogshall, of New-York—I would not give them that treatment. I may kick the hives, but the bees are subdued before I kick the hive. I had a boy take off 80 top stories last Tuesday without any trouble, because you may have a wrong impression about the kicking—when the bees are subdued, they are just as peaceable as can be, and kicking them doesn’t affect them; to kick off the top story wouldn’t hurt anything.

Pres. Root—I have noticed that in cutting down a bee-tree, as soon as the trees are cut down they go to work cross, but when one takes an axe and begins to chop away at the tree the bees seem to be demoralized. Sever smoking is liable to induce robbery.

**Spring Dwinding and the Remedy.**

"Is spring dwindling a disease? If so, what is the remedy?"

Dr. Miller—How many think it is a disease?

Mr. Kluck—Old bees, is it not?

Mr. Abbott—What do you mean by disease?

W. Z. Hutchinson, of Michigan—My idea of spring dwindling is imperfect wintering. They need to have good food. Good food is the pivot of success. They need to have good food and protect the bees you will not have spring dwindling. I think spring dwindling is the result of poor wintering, and you would not call it a disease, unless an overloading of the system from confinement constitutes a disease.

Mr. Abbott—Doesn’t a cold spring have anything to do with it?

Mr. Hutchinson—I think it would have something to do with it.

Mr. Abbott—I would like to suggest that spring dwindling is frequently the result of feeding. I have known a great many people to kill off their bees with feeding. Take the average farm bee-keeper and he is as likely to cause spring dwindling by feeding his bees as to do them any good, if he feeds them late in the fall. A great many bees are provoked to fly away in the spring by feeding them when, if they were left alone, and not fed at all, would not break the cluster, and the result is they wear themselves out and usually die from the overcurrent of energy that they lay eggs. Some people wonder why it is, and say they followed the bee-books, but the man who isn’t intending to use brains in connection with bee keeping is going to get better off without them, especially when it comes to feeding. Farmers come to me and say, "I thought my bees were a little subdued, but I gave them syrup, and put it under the hive, and I have been feeding them for a long time," when the mercury was standing down below freezing, any phrenics and a man who feeds bees when the mercury is in that condition is simply producing spring dwindling; and if you should define disease as an abnormal condition, I should say it was a disease.

Pres. Root—As I understand Mr. Abbott, feeding in the spring has a tendency to cause the bees to fly out, and they become chilled and do not go back.

Mr. Abbott—Not only that, but the over-activity of the bee exhausts its vitality.

Mr. Hutchinson—I thought it was the result of imperfect wintering.

Mr. Abbott—I don’t believe it.

Mr. Hutchinson—Mr. McEvoy, in Canada, has very good success in wintering his bees, and he crowds them down on five or six combs of solid honey, and does that so that they can not breed towards spring, and if those conditions are good they will carry the feebles till they are full, and will not take any more food. He feeds that in the fall.

Dr. Miller—I confess, to begin with, that I do not know what is the cause of spring dwindling. It is a matter of exceeding consequence sometimes to all of us, and I would like very much if you could give me the cause of it. In the first place, I think we all would be very likely to agree that it is not a disease. It is a condition. Not such a bad condition as a disease, and a condition that has been started are all in the line with the observation of any one who takes an interest in a thing and thinks about it at all. It would be worth something to us if we could get down to find out what is the condition that is produced. Now, it may be true, for instance, that the people who are interested about it will find out that condition, but what is that condition? Will feeding and making them fly out at inopportune times make them go away, or that they have less brood? Is there is of spring dwindling? Is it simply the fact that a number of bees have flown out and become lost? That is not spring dwindling according to my observation. It is something more than that. I don’t know that I know what that condition is, but I will say this much about it, that when you find spring dwindling in colonies you will almost always find that the number of bees present in the hive compared with the amount of brood is always small. This I think is the main fact. Whether in fact, whether the observation of my friends here agrees with that. Is that the common thing? It has appeared to me to be the case that, whenever I had a case of spring dwindling, there were too few bees in the hive to take care of the brood that was there. Now, if this is a common thing, I would like to know it.

H. L. Case, of New-York—A few years ago, in the latter part of April, I lost thousands of bees by what I called spring dwindling. The fall before my bees gathered a large quantity of honey-dew, and the winter was a severe one; it kept them in the hive nearly four months without giving them a flight. Now, I believe the reason I had spring dwindling that winter, or that spring, was that they were accustomed to the conditions were improper for their prosperity; if they had had one or two good flights in the autumn, so that they could have been refreshed, and have a good flight, I think it would have been better. I saved only 20 small colonies, and after the first good day that we had when the bees could fly out I didn’t lose any more bees to speak of. Now, I agree with Mr. Hutchinson, that improper feeding and the conditions through winter, confining them to the hives, and consuming too much food, made them lazy, and they could not get out to relieve themselves, and the result was that I lost some 80 colonies.

Pres. Root—It is very evident that there are a great many causes that induce spring dwindling.

Mr. Kluck—Would the gentleman state the time when the bees gathered that honey-dew?

Mr. Case—It was the forepart of September. I went bee-hunting at the time, and spent much time hunting wild bees, and there was so much honey-dew on the forest leaves in my section that they would not pay any attention to honey, I could not get them not to go into the forest and it would seem as if there was a swarm of bees, and they filled the hives full, from 25 to 100 pounds of honey in the hives, in the course of, as I remember, five or six days, and they sealed it nicely, but I couldn’t do much, and let it go, with the result that I lost 80 colonies.

Pres. Root—How many have had experience with spring dwindling?

Dr. Miller—Now, Mr. President, you would ask how many have had cases of spring dwindling in which little or no brood was present in the hive.

Pres. Root—If I understand the Doctor, he finds a condition which he sometimes sees, and which he observed along in March, when the bees evidently see that their numbers are small, and that they must have some brood to keep up their numbers, and the brood of little or none more than they can take care of, and they spread out too much and die on the outside edges. I have seen the bees so spread out on the batch of brood that they would all die.

Dr. Miller—Further than that, I have had a number of cases where there were too few bees, and as the brood was needed to go to work on, I kept and have apparently had a consultation and decided it was too much for them, and then all swarmed out.

E. A. Breithaupt, of New-York—I had a colony very strong with bees. I sent for a good queen and introduced her the next spring. I happened to be there so that I could watch, and I
looked in occasionally. I noticed, with that colony, that had so many old bees in the field, it began rearing brood much earlier than any of the others, and the queen did not go out. It was a condition of exhausted vitality, as you have just said. They get in a hurry about rearing brood to see if they could not possibly save the colony.

Pres. Root—The remedy, it would seem, would be implied from the discussion. It would be protection, proper feeding, if it be the right time, and those are conditions that we can very well meet.

Dr. Miller—If there is anything like colony disease in your district, when one thing in the remedy would be to have a large quantity of young bees in the fall, and anything that would tend to that—but I confess that I do not know whether my diagnosis is right.

Pres. Root—Proper feeding, proper protection, food properly given—and when I say protection I mean in double-walled hives or indoors, a proper indoor ventilator with sufficient ventilation. All these things may help to offset unusual conditions that we can not control in the way of weather, and then we can do the rest.

J. S. Barb, of Ohio—I had experience in spring dwindling, and I find that double-walled hives are not very much better than single ones. As a general thing, you will have a lot of old bees to start with in the fall, and that condition prevents them from rearing brood in the spring.

Pres. Root—I have noticed that—measurable not to get in condition without protection. Last winter, by oversight, we left out 10 small colonies without double walls, and many of them got down to a handful. Those that were right alongside of them in double walls got through all right. It all depends upon what we understand by disease. If we take Mr. Abbott’s definition of abnormal condition, then it is a disease.

Dr. Miller—Suppose you had a colony with nothing but drones in it, would you call that disease?

Mr. Abbott—A bad one, worse than a convention with no women.

Dr. Miller—How many think that spring dwindling is a disease?

Pres. Root—Let us have a show of hands. How many think spring dwindling is a disease? Now, how many think it is not? Evidently the convention doesn’t think it is a disease.

DISINFECTING FOUL-BROODY HIVES.

"Is it best to disinfect foul-broody hives?"

Dr. Mason—Yes, it is just as important to disinfect a hive as it is to disinfect a disease.

Wm. McEvoy, of Ontario—Why not burn it up?

Dr. Mason—It doesn’t pay. It is cheaper to disinfect it. Understand me, the question is, ‘a foul-broody hive.’

Pres. Root—The question as I understand it involves a diseased hive in which there have been bees that have had foul brood, that naturally was the intention of the question.

Dr. Mason—If the question is the intention may have been, I think that Dr. Mason raises a good point there, and there is a prior question to be answered. When a colony of foul-broody bees has been in a hive, is that hive always a foul-broody hive? That is the point he wants raised.

Pres. Root—Is a hive that has contained bees that have had the foul-broody disease necessarily a foul-broody hive?

Dr. Mason—I am sure that just as easily as saying that.

Mr. Kluck—According to Mr. France, the foul brood inspector of Wisconsin, he claims that a foul-broody bee in a hive is necessary to disinfect that hive. He gave us to understand in our bee-convention of northern Illinois that that was so.

Mr. Abbott—What is the remedy? I have thousands of experience in the test cases for pretty nearly 25 years, and I have never had a single hive disinfected in any way.

Mr. Abbott—Wouldn’t it be a good idea if we would bring out exactly what foul brood is, and what is the nature of the disease, and where it manifests itself? If it is a germ, understanding that, could we develop that germ?

Dr. Mason—That is, where do they locate? We know that the germ of tuberculosis locates itself in some of the glands of the human body, and that if you get the germ of tuberculosis out of the system, then the disease will be gone. That is, where do they locate? We know that the germ of tuberculosis locates itself in some of the glands of the human body, and that if you get the germ of tuberculosis out of the system, then the disease will be gone.

Mr. McEvoy—This man has asked one of the most important questions that I have ever heard put in my life. Honey, to become diseased, must first find its way into the stained-marked cells, that is, a cell where the matter has dried down, or where the bees are making room for more honey, when they move the honey from an unfilled cell to cells not finished; but when honey is gathered from the fields and stored side by side with these stain-marked cells, is the need of a cell that sound. It is the only possible way to spread it. Now, take combs from a diseased colony, I don’t care how badly it may be affected, if the bees are removed from those combs and the honey is put into a new, sound, and that never had brood in, and extracted, and the combs given back to the bees when they are clean, these combs can be used in any hive in the world and not give disease.

Mr. Abbott—Now, then, germs appear in two conditions, the active or the sporadic condition. When in the sporadic condition. A germ, when it is active, can be destroyed—I might say in the egg condition. Now, is the germ of foul brood in the egg condition in this dry brood or that? Is the sporadic condition and carried out with the honey and developed with the honey that is put into this cell when it is in that condition? I don’t understand the terminology? Is it true that, if I understand it and can not carry or communicate itself to another cell, and can only be imparted to another cell that is actively diseased, and such a condition created as will hatch the egg and thus spread it out?

Mr. McEvoy—Or that honey moved to another cell will do it. As far as I ever went, I know that the honey falling from these cells will give the disease.

Mr. Abbott—Now, then, if that spore, as the scientific men would call it, is placed in another cell, evidently it will develop. If that spore was loaded on the side of a hive and in the same possible condition by which that spore would develop on the side of the hive. If it would, why, then, you would have to change your answer?

Sidney S. Sleeper, of New York—Now are these germs vegetable or animal? In speaking of spores, that would indicate that they were vegetable germs; in speaking of eggs, that would indicate that they were animal germs.

Mr. Abbott—I simply wish to say that I used the word egg so that those people who haven’t spent 25 years studying science will know what I mean.

O. L. Hershizer, of New York—Can this dried matter move itself? What I mean is, that when the bees are moved from diseased cells, then one honey is diseasing the other; but as far as it going out from these cells through the hive and entering other cells, I do not think it is possible.

Dr. Mason—What do you mean by its going out?

Mr. Hershizer—What I mean is, that it would sort of rise and go through the colony.

Pres. Root—What he means is, whether the disease would pass through the hive from one cell to another cell?

Mr. McEvoy—It does not do that.

Dr. Mason—I don’t believe it does.

Mr. Miller—I want to confess that if the wildmen would take me out on that, I had gotten it into my head that these things were animals, and that they were eggs.

Mr. Abbott—Germs are animals, sometimes.

Dr. Mason—Are foul-brood germs animals?

Mr. Abbott—I don’t think anybody in the house knows.

Dr. Miller—I think if we talk of them as seeds there will be less danger of misapprehension. Suppose the spore is the germ of this hive. Now, if those spores were there in connection with honey, and the bees would take that honey, then you might get the disease from that hive, but I can’t conceive of it in any other way.

If there are spores there on the sides of the hive the bees are not going to take them up in any way. I understand Mr. McEvoy to hold that view, and it seems to me that that ought to make it pretty clear; and I confess to you that I never saw it as clearly as I do tonight. It may be that we are seeing at one time straightened out before, why he insists upon it in opposition to the views of a great many practical men, that it is not necessary to cleanse the hive, because if the spore is not in the honey of the bacilli are there—they are going to die, aren’t they, Mr. Benton?

Frank Benton, of District of Columbia—And I have no doubt; they might stay there and retain sufficient life to develop. But there is no bee going to take a spore from a dry hive and take it out with it.

Pres. Root—The spores are in an inactive state; the bacilli are in an active state.

Mr. Hershizer—I have frequently, in working around a hive, spilled a good deal of honey and it has run down the sides of the hive. Suppose these
spores were present and the bees would carry them into the cell and there develop into a larva. Isn’t that a case where the disease could develop?

Mr. McEvoy—Certainly.

Mr. Laenhof—Sometimes we are working with a hive where we do not give them the opportunity to secure the honey. Suppose they take the honey that is running down the side of a hive, and take it into a cell where there is a larva, wouldn’t that communicate the disease?

Mr. McEvoy — Ninety-nine parts out of a hundred of it are pure.

Pres. Root—As I understand Mr. McEvoy, he speaks of a small portion of the honey being diseased his recommendation is that all the combs or wax be burnt. In order to be sure, he considers it safe to burn every comb.

Mr. McEvoy—Yes, sir, every comb.

Dr. Mason—I have had a good deal of experience with foul brood, and I do not exactly agree with Mr. McEvoy because he is the best authority we have. I consider it advisable, in my experience, to take foul-brood bees, combs, etc., out of a hive and use that hive without disinfecting. I have kept them and have not had any trouble, but they were out of there with the greatest of care and crush a bee with foul-brood honey in it and leave it there, and when it is so easily disinfected, I don’t see why it should not be done; but if a hive has foul-brood honey on it, or in it anywhere, it is a foul-brood hive and needs disinfecting, and even Mr. McEvoy admits that.

Dr. Miller—I want to ask Mr. McEvoy if he ever tried using a hive again that had foul-brood bees in it.

Mr. McEvoy—Oh, thousands of them.

Dr. Miller—I would like to know definitely. I want to know something detailed in numbers. Did you ever have half a dozen or more of them in that way, or how many? Give us something definite about it.

Mr. McEvoy—I don’t know, I suppose I could put it safely at 5,000.

Dr. Miller—Of that 5,000 how many of them ever succeeded in giving the disease?

Mr. McEvoy—Not one, that I ever knew. Not a single case. That I ever knew.

Dr. Miller—Now, if in 5,000 cases that you have tried there has not been a single failure, I am willing to take what risk there is.

Pres. Root—After I had learned of Mr. McEvoy’s experience, in which he had tested something like three or four thousand hives at that time, I concluded that we would try to cure the disease without boiling the hives, and ever since that time we have found that we could cure it just the same without boiling the hives. Some years ago, when we had them all through our apiary, we boiled all our hives, but we left about 10 of them and thought we would see what would result. I think that there were four or five out of the ten that we left that had the disease, but I have thought since that that experiment did not amount to anything, in view of what Mr. McEvoy says that he has tried it in 5,000 cases.

Mr. Hershiser—I would like to ask how many of these apriaries have been treated more than once and how many times those apriaries have been treated that have had foul brood?

Mr. McEvoy—that is a close question, as you know. It is one thing to handle a disease and it is quite another thing to handle the men. Some men make a perfect cure, others a partial cure, and have to go to several times, and it is just how they do the work. Some of them will blunder once in a while, but it isn’t the cure; the problem was how to do that work; they often put it like this, “Well, how long will I boil the hive?” Now, that depends upon how long you intend to boil the bees; surely, you are not going to do one without another. Are you going to take these bees that have walked all over the putrid eggs, with their dirty little feet, without boiling them? If you are going to boil the hive half an hour, I think you ought to boil the bees an hour. And I don’t know a place in Ontario where they boil now.

Dr. Mason—Foul-broody hives need disinfecting just as surely as do foul-broody bees, and they can as surely, and more easily, be disinfect without boiling than can bees.

Pres. Root—Perhaps it ought to be stated that Thomas William Cowan, and quite a number of scientists across the water, feel that it is very necessary to disinfect the hives, but, as I have stated, we haven’t disinfect our hives since, and we haven’t had any trouble.

Dr. Mason—You haven’t had foul-broody hives, then.

Mr. Miller—It seemed to me that it was a foolhardy piece of business for Mr. McEvoy to insist that there was no necessity for disinfecting, for it seemed to me that there must be plenty of spores, but if you come to think about it, what is going to take those spores where they can do any harm? And the fact remains that if he has had so many cases, and if the results have come from us, we ought to be able to go on and do what he has done.

W. H. Helm, of Pennsylvania—should I like to ask Mr. McEvoy why these are the only two remedies for the disease—by burning the combs or boiling?

Mr. McEvoy—Do you mean that you think that they can be disinfect?

Mr. Helm—Mr. McEvoy—You can use the disinfectant till those combs will fairly smoke, and you try them over again and it will break them. Pres. Root—I talked with Mr. Gemmill and one of the other inspectors, and asked if his experience coincided with Mr. McEvoy’s, and he said it did.

A Member—Do I understand Mr. McEvoy that the combs should be burned up, or made into wax?

Mr. McEvoy—I think they ought to be all turned into wax, and made into comb foundation. It is all right, too.

(Continued next week.)
ants immediately began to move to places of supposed safety. The terror of the ants did not soften my hard heart. Calling the chickens, I soon had the satisfaction of seeing a brown leghorn pullet begin the work of destroying the larvae of the colony of ants that had made their home under my beehive. How she did seem to relish every fat pupa! And how quickly the other chickens learned to like ants' brood!

The queen and her fellows, except for those reared in this manner, are doomed. Perhaps the black ants which fought my bees are not the "small ants" which "neither molest the bees nor are molested by them." At any rate, it seems worth while to report them. Perhaps the wise hive will claim them. Perhaps they will tell me that I ought to have killed the ants long ago. At the risk of needlessly exposing an ignorance which is frankly confessed to be great, I venture to add that this particular hive became queenless during an era of scarcity. When the brood was supplied with two frames containing brood in all stages from the egg to the hatching bee, and that at one time there were two or three well-developed queen-cells in the hive. Is it possible that the ants might have robbed the queen?—Arapahoe Co., Colo.

**Working for Italian Bees—Pure Mating of Queens.**

BY G. M. DOOLITTLE.

**QUESTION**—I have spent much time during the past summer to Italianize my bees, and think they are now all pure Italian. But my Italian queens are kept as hybrid bees, kept in box-hives, so that hosts of drones are reared in these during the summer. Do I wish, if I were rearing queens for my own use, can secure them purely feducated.

**ANSWER.—**There are several plans for the pure mating of queens, but, up to this time, all are more or less faulty. The best of these plans are the following:

In the early spring, as soon as you can find colonies which can spare it, give capped brood to your drone-rearing colonies, and this, together with a little warm feed, given each day, will cause the desired queens to lay in the drone-comb early, through the stimulation given, thus giving you strong colonies of plenty of drones, before your neighbor's colonies rear any drones.

To secure the best results, one or more drone-combs should be placed in the center of the brood-nest at the time you give the sealed brood. As soon as any drone-brood has been capped from 3 days to a week, start to rear queens, and in this way you will have your queens ready for the first drones which appear. The main objection to this plan is, that such rearing of queens comes at a time when it is likely to interfere with your plants; for in all queen-rearing the colony is thrown out of its normal condition; and whether the old queens are taken away from their colonies to give place for the desired queen-cells, or nuclei formed to take care of these cells, this interference comes at the wrong season and would be bound to bring along the line of rearing the bees in time for the honey harvest, which, as a rule, will be from 30 to 50 days ahead.

If I may be pardoned, I will say that I should consider impure stock, with a good yield of honey, very much more preferable than absolutely pure stock and little or no surplus honey.

Another plan is, to wait till fall about rearing queens, if you can preserve the desired drones, till all of your neighbors have decided shall be drones all mothers, and mass this brood in one hive, tiering it up, if necessary, to accommodate this brood and an abundance of honey; for, the larger the hive and the more honey it contains, the better your chance of having the drones preserved in numbers, because the queenless colony of drones is the queen should be taken away from the colony; and as often as a new queen comes to lay she should be taken away also, and this colony kept supplied with sufficient worker bees to keep it going, for it is the condition of a perous condition depends the freeness of the flight of the drones on every suitable day. If you wish all of the drones which your queens are to mate with to be strong, robust fellows, on some cloudy day when the bees are not flying so as to endanger robbing, look this hive over and hand-pick the drones, killing all which you think are not as such as you would desire. To do this best, take out the first comb and pick out as above, when it is to be put into an empty hive, set on the stand originally occupied; and thus when you have gone over every comb, and such drones as may cling to the sides and bottom-board to the hive, your colony is just where you want it, without any extra handling of frames.

You are now, in a measure, quite sure that the queens reared will come as near perfection as is possible along the line of right mating, and were it not that this plan requires much extra work, it is still a very good one. Instead of colonies, or one, or two, who may be taken a hybrid, or a three nuclei, supplied with virgin queens from the best mother, these being from 3 to 5 days old, to this isolated place, leaving them there from 8 to 10 days, when they can be brought home with laying queens, which will, as a rule, be reared with the desired drones. With a proper rack fixed on any light spring wagon, from 12 to 25 nuclei can be carried to and fro at one time, so that this is not so very laborious as it first appears, and it has this advantage: The queens can be reared at any season, and any queen will be as perfect as itself, as in this way all can be reared in the height of the honey season, when the best queens can be reared with the least work.

Another plan is to rear the queens and drones in the best part of the honey season, and, when ready, take the drone colony and such of the nucleus as havequeens of mating age, to the cellar, or some darkened, cool room, carrying them in before they begin to fly, in the evening, and leaving them there till 4 o'clock in the afternoon, or till all other drones have ceased flying for the day. If each nucleus and the drone colony are fed a little warm diluted sweet just before setting out, and the hives face the western sun, queens and drones will fly something as they usually do in the early afternoon, and the results will prove quite satisfactory.

**The Afterthought.**

The "Old Reliable" seen through New and Unreliable Glasses.

By E. E. HASTY, Sta. B Rural, Toledo, O.

"Unreading" one's self.

Yes, Mr. Weaver, it is sometimes a good plan for the beginner to "unread himself" and go in on his own hook. Bees differ very greatly; and a man often may be taken a hybrid, or have his eyes "unreading". There are some (and very provoking ones they are) that will all get in army formation and march out of the hive whenever they can get out, if you but manipulate their frames a little. Others are like yours. Howsoever, a beginner should take a watch along for such a job, and give them a reasonable number of actual minutes before unreading everything—otherwise his 10 minutes might be about 2 minutes. "All's well that ends well," but the main danger is that the queen may keep and strip of comb full of brood all the while. Even if zinc is used there is some danger of getting some new honey in very undesirable shape.

Glucose can be fed, but don't.

It is somewhat in the line of news to be told that one can feed a ton of glucose to his bees. Editorial, page 574.

Millionaire bee-keepers.

Want the names of millionaire bee-keepers, eh? Well, I'm one—own a million dollars' worth of independence and good hopes—and none of J. Pierpont Morgan's paper brugs in larger returns. People have more in proportion of real millionaires to ours. I take it. Page 574.

The virgin queen survives.

It is an interesting bit of experience from C. Davenport, that when two colonies are lived together, one with a laying queen and one with a virgin, it is usually the virgin which survives. That would naturally be the case where the bees do not ball either of them, but just let them fight it out themselves—virgin too spy for heavy old dowager. Page 552.
HOW THE SICILIAN BEE-KEEPERS DO.

We have closed standing frame hives both with and without outer shells; but the Sicilians are unique in plastering on an outer shell upon movable standing frames. The plastering is to be repeated after each manipulation, I suppose. With a framework taken out of the hive and the bees removed, you can curve the the frame around as in frames horizontally long, so quite possibly a bamboo top-bar might need no comb-guide. Page 582.

CAUSES OF QUEEN-REARING FAILURES.

And so Doolittle suspects that wrong moves in transferring the larva are responsible for most of the failures—the quite moderate percent of failures—in rearing queens by the Doolittle method. It is a shrewd test experiment which he suggests—e.g., take the larva from some natural cells which the bees undoubtedly cherish and see if you can put others in successfully. Page 582.

HUGGING TO DEATH.

We know that the same facts can oft be read in different ways. We are pleased to hear (pleased in one sense of the term) that bees are not trying to worry the drones to death—only hugging them in the affectionate effort to disembrace them from suicide. And if, to disembrace Mr. Archibald from the suicide of extracting from combs with brood in them, just the right body would didactically and effectively hug him—well, it would be a good deed. Page 587.

POSITION OF NECTAR-GLANDS.

I think Prof. Smíchek is hardly wise in his choice of words when he says that nectar-glands are concealed. The conditions prevailing here. They are present in the spots which bees are being lured to touch unwittingly, and concealment comes in as an undesirable result. Page 588.

"ENJOYING LIFE"—SELFISHNESS.

I like the talk from Gleanings in Bee-Culture, on page 589, about the philosophy and plan of human occupation and life; but, still, I greatly wish some one could give, intelligibly and victoriously give, just a little different turn to the phrase "enjoying life." I wish it associated with the enjoyment of life be a kitten running after its own tail. And in just that sort of a quest multitudes of well-bred, intelligent people make their lives into wrecks—make themselves unfit persons to be benefited. Much work is to be stayed in over night. We must have some banner before us which does not have "self, self, self," written all over it.

The Home Circle.

Conducted by Prof. R. J. Cook, Glaremont, Calif.

EDUCATION.

What a wealth of philosophy, and what a mine of truth, are to be found in the familiar scriptural adage, "The little foxes that spoil the vine." Is it not equally true that some little word, or apparently trivial event, makes a life a man? A fond teacher in my early boyhood—one of those rare persons who ever lived in the love, respect, admiration of all whose lives they touch—said a word that aroused in me a quenchless ambition for that which else I would never have secured. That word was "College." She said, what I have seen illustrated in many lives since that time, "If you wish it hard enough, you can get a college education; a thorough education would be worth more than a gold mine to you." I wish some happy parent, or some fortunate teacher, or some other good angel, could blaze this truth into the mind of every bright boy and girl the country over. We should wish most kindly and most earnestly that all our children should covet the very best gifts. Certainly high among the best treasures of any life is a rich, broad culture of the mind. Only one thing transcends it, and that is a rich soul-culture.

Were I to be a ditcher, or a stone-crusher in the hot sun by the road, I would wish education to be my companion then and there. The education would not only soonest lift me out of the ditch, and away from the stone-pile, but it would do even better, it would help me to enjoy the life with the spade and the hammer. One thoroughly educated can find real pleasure in the opening ditch or the break-

ling stone. Shakespeare was, as always, wise. Those with eyes to see can find books in the running brooks.

A good friend writes commending my "Home Circle" teaching, but wishes that a girl had not been taught, not Sunday, was the sacred day. Another wishes I could be consistent and vote for prohibition. I have no retort for either. We may well remember Paul's word, "Some esteem one day better than another; some esteem all days alike," Paul did not do this with a thrust at a party. He said, "Be well persuaded in your own minds." That is very wise advice. Let us all study both these questions, and all others that divide public opinion as thoroughly as we may, then decide as ca-

refully as we have studied, and then act upon our convictions. If we do this we shall please God, I am sure. If this results in our keeping Saturday, then well; if in keeping Sunday, then well. If it makes us vote prohibition, God will smile; if in our vote otherwise, God will frown. I do not demand perfection of any of us. "Only one, your father in heaven, is perfect." He does demand earnest, honest study, as a requisite to right judgment. The good education makes the hard study easier, and the succeeding judgment more cor-

rect.

THE Good education does, or ought to, do a better thing. It makes us charitable, tolerant towards others who have also studied and decided differently. It recognizes that all fail of deciding wisely and rightly at times; and instead of a word of criticism to them, we shall examine our own views, lest, perchance, we may be in error.

I keep Sunday, and generally vote the Republican ticket. I believe I please God in doing so. If my friends have studied it as they may, and have decided as conscientiously as the importance of the questions demand, then they, too, please God. God be praised for the best mind-culture. That not only helps us to right decision, but makes us kindly, charita-

table towards him who is led to different conclusions. The first of the most blessed things of our day is the greater tolerance which we give to those who think not as we do. Edu-

cation, clarified and sweetened by the Christ spirit, is the glorious parent of this broader charity.

LANDSCAPE GARDENING.

In my institute work of late, I have been happy in being associated with a bright landscape gardener and horticultur-

ist. His lectures have been of the highest interest, and I should control in all laying out of home grounds, whether in the restricted city lot or in the more spacious environs of country.

First, "Avoid straight lines.

Second, "Preserve open lawn centres.

Third, "Plant in groups, not singly."

I have listened more pleasantly as we have followed two of these rules in our own landscaping. We have no straight lines. Our walk or drive is softened as desirably as the other lines. Our little white clover lawn is all the richer and more thrifty in having all to itself. A tree or shrub in a lawn almost always looks as if it fell out of place. Its foliage looks sick and sickly. My plants are isolated in natural groups. They are not regular. On my small place I doubt if grouping would have given us more pleasure. Of course it would if more artistic, more after Nature's pattern. Is this true in such confined limits?

"DEAR DAUGHTER DOROTHY."

This is a charming story for the children. Like that fasci-

nating book, "Captain January," it should be in all our home circles where children abound. The book makes a child do impossible things, but in such a realistic way that we for-

get that it could not be realized in life. It is charming, too, to see how perfect is the union in thought and feeling between father and daughter. I can see my father's arms dangling to hang on memory's walls. I urge every home circle to get these two books, and read them aloud in the home circle. If the scene in "Captain January," where separation is pro-

posed, brings tears, and raises the heart throb-ward, we shall all be the better for it.

I remember how our whole household, years ago, gen-

erated dampness under the eyebrows, when we read "Uncle Tom's Cabin" aloud in the old home. It went hard to cry. Such scenes were always more interesting to the hearty class than to read. They were good tears, and were not without influence in the stormy days of the early sixties.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-

keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last.
FOR GETTING NEW SUBSCRIBERS.

Red Clover Queens FOR 1902 Free
Long-Tongue Variety—Warranted Purely Mated.

We have already arranged with the queen-breeder who furnished Long-Tongue Red Clover Queens for us during the past season, to fill our orders next season. Although fully 95 percent of the untested queens he sent out were purely mated, next season all that he mails for us will be warranted purely mated.

We want every one of our present subscribers to have one or more of these money-maker Queens. We have received most excellent reports from the queens we supplied during the past season. And of course our queen-breeder says he expects to be able to send out even better Queens, if that is possible. He is one of the very oldest and best queen-breeders. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, of beautiful color, very gentle, scarcely requiring veil or smoke. Orders for these fine, “long-reach” Warranted Queens will be filled in rotation—first come, first served—beginning as early in June as possible. It is expected that orders can be filled quite promptly (even better than the past season), as a much larger number of queen-rearing nuclei will be run. (But never remove the old queen from the colony until you have received the new one, no matter from whom you order a queen.)

All Queens will be guaranteed to arrive in good condition, and will be clipped, unless otherwise ordered.

A Warranted Queen for sending us Only 2 New Yearly Subscribers

In order that every one of our subscribers who wants one of these Warranted Queens next season can easily earn it, we will book your order for one queen for sending us the names and addresses of two new subscribers to the American Bee Journal and $2.00. FURTHERMORE, we will begin to send the Bee Journal to the new subscribers just as soon as they are received here (with the $2.00), and continue to send it until the end of next year, 1902. So, forward the new subscriptions soon—the sooner sent in the more weekly copies they will receive.

This indeed is an opportunity to get a superior Queen, and at the same time help swell the list of readers of the old American Bee Journal.

We are now ready to book the Queen orders, and also to enroll the new subscriptions. Remember, the sooner you get in your order the earlier you will get your Queen next season, and the more copies of the Bee Journal will the new subscribers receive that you send in. We hope that every one of our present readers will decide to have at least one of these Queens.

Address,

General Items

Had Good Honey-Flows.

My bees have done well this year. We had a good honey-flow the last of June and the first part of July from mesquite, catclaw, and alfalfa, and now have a good flow from alfalfa and wild flowers.

The American Bee Journal has been a great help to me in my bee-business. I do not see how I could have done without it.

J. S. Bridestine.

Hairy Vetch as a Honey-Plant.

In response to the request for information regarding the hairy vetch as a honey-plant, I can say this:

About six years ago I received from the Agricultural Department at Washington a package labeled, “Sand or Hairy Vetch.” I sowed a small plot with the seed, and it has grown there ever since, coming up every spring from seed grown there the year before, I suppose. It yields a fine forage, and blooms all summer—beautiful blossoms—but I never saw a honey-bee on one of the blossoms in all these years. Bumble-bees and butterflies.

Farming by Lottery.
The recent drought has emphasized the element of chance in farming under ordinary conditions, whereas on

AN IRRIGATED FARM crops never fall or are damaged by bad weather in harvest. The yield is larger, quality better and prices of the products higher.

Our Irrigation Settlement Plan
affords an opportunity for securing a well-located, irrigated farm at half the usual prices, on easy terms, with ABUNDANT WATER, RICH SOIL.

HOME MARKETS at good prices. Wheat yields, 56 bu.; oats, 100 bu.; potatoes, 300 bu.; alfalfa, 5 tons per acre regularly each year.

Development of the Queen.

In gleanings in Bee-Culture, Dr. C. C. Miller discusses the matter of queen development. After considering the time from the laying of the egg to hatching, and to the sealing of the larva, he says:

The most important of the questions, from a practical standpoint, is: "How long from the laying of the egg to the emerging of the queen?" In the American Bee Journal, Vol. I., page 191, in a review of the three articles on the Dzierzow theory, by the Baron of Berlepsch, after detailing some experiments, he says:

"These experiments show that the opinion generally entertained, that the queens emerge between the 17th and 18th day after the eggs are laid, is correct."

The time of writing this, however, antedates the publication of the Journal, 1901; and elsewhere in general throughout the volume 10 days is accounted the proper time. Indeed, page 306, Dr. Cowan gives a special case in which the time was only 15 days. Sixteen days has of late years been accounted the normal time. I think, in general, in all the books excepting Cowan's, which gives 15 days. This year I thought I would refer the two latter questions to the bees, so as to get a positive answer in at least one case. July 18, at 10 a.m., I took from No. 85 its brood, leaving in the hive foundation and one comb containing some sealed brood. This comb having been kept for more than a week, I thought, there was no possibility of a queen laying in it. Four days later I gave this comb to No. 25, after having removed from No. 35 its queen and brood. July 28, at 10 a.m., when the oldest brood could not have been more than eight days old, I found 20 sealed queen-cells on the comb, and seven unsealed. The proof is clear and positive that those 20 cells that were sealed contained larvae not any more than eight days from the laying of the egg. It is reasonable to suppose that the seven unsealed cells contained younger larvae. Desiring to save all the cells, I did not wait till all the occupant had emerged. From the laying of the egg, and opened the hive at 9:45 a.m., Aug. 2, I was doomed to disappointment, for seven young queens had already emerged. In this case there could be no question. The cells were sealed in eight days, and allowing three days in the egg, there were five days of feeding; and the queens emerged to days from the laying of the egg. These figures agree with those of Mr. Cowan. It should not for a minute be supposed that there is any kind of variation. But it is probable that, under normal conditions, they may

ALFALFA HONEY
This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey
This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a similar flavor than Alfalfa, and is preferred by some who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:
A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 8 cents per pound; four or more cans, 7½ cents per pound. Basswood Honey, ½ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are boxed. This is all

ABSOLUTELY PURE HONEY
The finest of their kinds produced in this country.

Read Dr. Miller's Testimony on Alfalfa Honey:
'I've just sampled the honey you sent, and it's prime. Thank you. I feel that I have something of a heroine to sell several thousand pounds of honey of my own production and that buy honey of you for my own use. But however loyal one ought to be to the honey of his own region, there's no denying the fact that for use in any kind of hot drink, there one prefers the more wholesome honey to sugar, the very excellent quality of alfalfa honey I have received from you is better suited than the honeys of more marked flavor, according to my taste.

C. C. MILLER,
McIlhenny Co., Ill.

Order the Above Honey and then Sell It.
We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.
be relied upon as coming near the average as anything that can be given. The question may arise, why is it that 16 days for the full development of a queen from long development will be retarded. In the American Bee Journal, Vol. 1., page 148, Father Langstroth reports a case in which a queen in a nucleus was 21 days in coming to maturity. In my early days of bee-keeping I knew no better than to have several queens started in nuclei, and I had cases like that of Father Langstroth. But in full colonies I have had many, many incidental proofs that 15 days is the limit. I ought not to change our belief from 16 to 15!

Hiving on Foundation.

Foundation, full sheets of it, is something that a newly hived swarm does not like; at least, Messrs. Hall and Alspaugh, of Ontario, assert that such is the case; that they are much more likely to swarm out when hived on full sheets. Mr. Alspaugh says he believes that bees don’t realize at first what foundation is for—that they don’t comprehend at first that they can make combs of it. When they find themselves in a hive filled of full sheets of wax placed 1½ inches apart, they say ‘I see no good in this; I am not going to be a there is no opportunity to build comb here with the space all divided in this way. Let’s get out of this and return to our honeycomb in an empty box, which gives the bees an opportunity to cluster contentedly in a natural manner, and then set a hive, furnished with sheets of foundation, over the box. Gradually the bees change from the foundation, discover its nature and their opportunities, and box below will be deserted—but sometimes not until quite a little comb has been built.”—Beeker’s Review.

Introducing Queens.

Mr. Ally has introduced thousands of virgin queens by the following method: The nucleus is placed on the hive, and 72 hours—then the entrance is closed with a plantain leaf, the bees given a dose of tobacco-smoke through the feeders. The hive, and the queen immediately run in through the same place, and the hole is closed. By morning the leaf is dry, the queen has flown away, and offers no obstruction to the bees. He uses the leaf to keep the bees in, and so to prevent the new queen from the swarm, for they are not likely to enter the hive as they are entering the hive.”—Arthur C. Miller, in the Bee-keepers’ Review.

Prevention of Increase.

Although not prevention of swarming, it is given after this fashion in the Bee-keepers’ Review:

Hiving swarms so as to prevent increase, and secure good results in honey, is managed as follows by Mr. J. B. Hal, of Ontario: The first swarm is hived upon half a stand, and the old hive placed by the side of it. On the eighth day all the bees (queens and all) if the honey is in a separate chamber, or the bees are hived in this place. On the eighth day before the old stand; any recipient where the nectar is mashed down, and

Standard Belgian Hare Book!

BY M. D. CAPRI

THIS book of 172 pages presents a clear and concise treatment of the Bel- gian rabbit, as well as its growth, origin and kinds; the sanit- ary and constructive character of the rabbit, breeding, furs, and furraising, the varieties, their care, scoring, etc., in which they may be recovered, together with a section on all the rabbit raisers’ diseases, and their cures and their diseases and their safekeeping. A first edition of 500, 20c., was sold in advance of publication.

Price, in handsome paper cover, 25c., postpaid; or with the American Bee Journal one year—both for only 11.50.

$13 to Buffalo Pan-American and Re- turn—$13, via the Nickel Plate Road daily, with limit of 15 days; 20-day tickets at $10 for the round-trip $13 for the round-trip on Tuesdays, Thursdays and Coaches. Through service to New York and Boston and lowest avail- able rates. For particulars and Pan- American folder, write to Y. Calahan, Gen- eral Agent, 111 Adams Street, Chicago.

WILL SELL my half interest in one of my armies containing 200 colonies, for $6,000, or C. R. K. Have too many hives in the fire to attend to the request. At your command.

HONEY AND BEESWAX

MARKET QUOTATIONS

CHICAGO, Oct. 10.—There is a very good trade in honey at 8¢ per pound; that which will not grade 1c. Lot fancy sell at from 13¢ to 14¢; some small lots of fancy have broken 17¢, and the dark honey has broken 13¢ to 15¢; the dark honey of various grades ranges from 7¢ to 9¢; the honey from both broods is of a good dark color and is full of flavor; it is very well at 55¢ to 60¢ for white, according to quality and flavor; white clover and basswood bringing 7¢; light amber, 55¢ to 60¢; Beeswax steady at 26c. R. A. BURNETT & Co.

CINCINNATI, Aug. 16.—The honey market is rather dull on account of the weather. Extracted sells only to manufacturers at 50¢ per 100 pounds in cartons, 9¢ to 10c; better grades alfalfa water-white from 64¢ to 70c; white clover from 80¢. Fancy white comb honey sells from 135¢ to 150c. C. H. W. WEBER.

BOSTON, Aug. 8.—Fancy l-pound honey in cartons, 10c; A. No. 1, in glass bottles, 13¢ to 15¢; A. No. 1, 14¢ to 15¢; very little No. 2 being received. Light extracted to 60¢. BLAKE, SCOTT & LEE.

Baltimore, Aug. 27.—White clover honey is in good demand and is firm at 70¢ to 72¢ per pound, with 50¢ on the New York market. White, 73¢ to 74¢; 100¢ to 120¢. O. B. MILLER.

OMAHA, Aug. 8.—Comb honey is arriving in express in small quantities from Colorado and selling at $3.50 per case. A retail price for the fancy white, 13¢; domestic clover, 10¢. E. L. DAVIS.

SEATTLE, Aug. 10.—The market is quite steady at the present time. The fancy white, 13¢; domestic clover, 10¢. L. J. MULLEN.

NEW YORK, Oct. 18.—Comb honey is in good demand and finds ready sale at the following quotations: Fancy wild, white, 13¢; domestic white, 15¢; amber, 12¢; buckwheat, 10¢ to 11¢. Fancy clover and alfalfa water-white, 90¢ to 100¢. A. H. STEEL.

DURHAM, Aug. 7.—There is very little doing here in new crop of honey. Some small lots of near-by produced comb honey are on the market and selling in a narrow range at 75¢ to 80¢ per pound. Light extracted at 60¢ to 65¢. No. 2 grade. C. W. HEDRICK & SKEEOLEN.

DENVER, Aug. 9.—Honey is very sluggish at this time and very little selling, a few small lots being received during the past week. Fancy white, 105¢; domestic clover, 95¢; domestic water-white, 65¢. P. F. JONES.

NEW ORLEANS, Aug. 13.—Comb honey is in good demand, and we find the price 70¢ per case. Fancy white, 13¢; domestic clover, 10¢. F. A. GERMAN.

DALLAS, Aug. 9.—Honey is steady and for the most part is in a narrow range. Fancy white 13¢; domestic clover 10¢. A. D. DURMEN.

SAN FRANCISCO, Oct. 9.—White comb, 105¢; domestic clover, 90¢; alfalfa, 85¢; extracted, white, 60¢; light amber, 45¢; brown 40¢. M. H. HUNT & SON.

Catnip Seed Free!

We have a small quantity of Catnip Seed which we wish to offer our readers. Some consider catnip one of the greatest of honey-yielders. We will mail to one of our regular subscribers without charge 250 seeds. We are introducing ONE NEW SUBSCRIBER to the American Bee Journal for a year with $1.00; or will mail any one an ounce of the seed for $1.00. We want from subscribers all over the country—both for $1.30; or will mail an ounce of the seed alone for 35 cents.

GEORGE W. YORK & Co., 144 & 146 Erie St., CHICAGO, ILL.

Rocky Mountain Bee-Plant Seed!

(Coleome integrifolia)

...FREE AS A PREMIUM...

The A.B.C of Bee-Culture says of it: "This is a beautiful plant for the flower-garden, to say nothing of the apiary, as the bees are always on it from two to three feet in height and bears large, clusters of bright pink flowers. It grows naturally on the Rocky Mountains, and in Colorado, where it is said to furnish large quantities of honey." We have a few pounds of this Coleme seed, and offer to mail a 3-feed package, as a premium to any one subscribing for ONE NEW SUBSCRIPTION to the American Bee Journal, with $1.00; or 3

GEORGE W. YORK & Co., 144 & 146 Erie St., CHICAGO, ILL.

CONVENTION NOTICES.

Chicago.—The Executive Committee of the Chicago Bee-Keeper's Association has ordered that the next meeting be held all day and evening, Dec. 5, 6, at the Briggs House club-room. This is arranged on account of the low rates to be had for railroad transportation, and nearly 300 bee-keepers are expected Chicago, and should result in the largest attendance we have ever had. C. C. Miller and Mr. C. P. Danday have promised to be present. Let all come.

GEORGE W. YORK, President.

Colorado.—The Colorado annual meeting promises to be a genuine success. The program has been well planned and a number of excellent papers are almost ready for publication. It has come to be a privilege and an honor to read a paper before the meeting of the Society. We have had in the past few years so many who are invited to write or speak for instruction and entertainment of the members in the board of the secretary. On two or three nights a big magic lantern will illustrate talks by famous students of bees and the bee industry. And then we are going to have an exhibition of the choicest honey in the United States (made in Colorado, we know) and wax, with bees enough to show "The Beekeeper's Garden". If you want to know more, or have forgotten the dates Nov. 18, 19, 20, write to the undersigned, here. Denver. D. W. WORKING, Sec.
We have a Large Stock on hand and can ship promptly.

RED CLOVER QUEENS

BLACK ROCK, N. Y., Sept. 3, 1901.

FRIEND ERNEST:—I will try and tell you what you want to know about that queen. I got her of you in 1899 as a premium with GLEANINGS. I never saw a small colony of bees build up as that one did. In the spring of 1900 they came out in fine shape, wintered perfect. I raised them up in May and gave them 8 frames more so the queen would not want for room. I never saw such a colony of bees as they were in June, and they were actually storing honey when other bees in my yard were starving. No! they were not robbing. I never saw those two best colonies of mine trying to rob. THEY CERTAINLY WORK ON RED CLOVER. This is no guesswork, as I have seen them. As you know, the past two seasons have been very poor, and what honey my bees did get in 1900 candled soon after cold weather set in, I packed this colony in a chalk hive and left them out, thinking that such a strong colony would winter perfect. The snow came on the middle of November, and those poor bees never a fly until the last of March or the first of April. When warm weather at last came I thought they were dead, as they did not seem to be flying much, so I did not pay any attention to them until in June. I noticed they were working a little, so I opened up the hive and found them in the upper story. I took the lower story out and left them in the one body. The queen was laying nicely, and I thought they would make a good colony to winter. Along the last of July I noticed that they needed more room. I gave them super, 31 boxes, and in a few days they had it full. They have made 72 boxes of as nice honey as you ever saw, and are drawing out some starters now, Sept. 2.

Very truly yours,

Geo. B. HOWE.

Langstroth on... 
The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helpt on the way to success with bees.

The book we mail for $1.25, or club it with the American Bee Journal for one year—both for $1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with $3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.
144 & 146 Erie Street, CHICAGO, ILL.

THE
The Bee-Keeper's Guide;
Or, Manual of the Apiary.
—BY—
PROF. A. J. COOK.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without The Bee-Keeper's Guide.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to present subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with $1.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for $1.25, or we club it with the Bee Journal for a year—both for only $1.75. But surely anybody can get only TWO new subscribers to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,
144 & 146 Erie Street,
CHICAGO, ILL.

The Novelty Pocket-Knife.

Your Name on the Knife. When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown below.

The material entering into this celebrated knife is of the very best quality: the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The holsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire: the linings are plate brass; the handles are inlaid with celluoid, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your Pocket-Knife will serve as an identifler, and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side. The accompanying cut gives a fault idea, but cannot convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife. We send it postpaid for $1.25, or give it as a Premium to the one sending us THREE new subscribers to the Bee Journal (with $1.00). We will club the Novelty Knife and the Bee Journal for one year, both for $1.90.

GEORGE W. YORK & CO.
St. Chicago, Ill.

**Please allow about two weeks for your order to be filled.**
National Association Elections are held annually in December, that is, the election of general manager and the successors to three members of the board of directors, whose terms expire with the end of each year. The executive committee (composed of the president, vice-president and secretary) are elected at the annual meeting of the organization.

Referring to this subject, though more particularly to nominations in advance of the election, Editor Hutchinson said this in the Bee-Keepers' Review:

Nominations in advance of the election of a general manager, and the directors of the National Bee-keepers Association, would be very desirable. As it is now, when a member receives a voting-blank, he does not know for whom any other member will vote. In his desperation he votes for the man whose term of office is about to expire. As a result, each officer succeeds himself, year after year. Should it ever become desirable to elect a new man, it would be well-nigh impossible with the present system. This question was discussed by the directors present at Buffalo, but they were unable to devise a plan that seemed wholly satisfactory, and it was finally decided to have the matter taken up in the bee-journals for discussion.

The foregoing was sent to F. B. Root, one of the directors, for his criticisms or suggestions. When considered briefly, he replied: "I believe that the more prominent and wiser members should manage its important affairs."

Long Tongues Per Se.—In the Bee-Keepers Review for September, F. B. Simpson disclaims the intention of teaching that long tongues are of no value per se. It was said on page 63 of this journal that it was doubtful if he meant to teach just that thing. But his words—"I believe the long tongues are of no value only so far as they represent an increase of rigor—seem to teach just that thing, at least a Straw in Gleamings in Bee-Culture, and an "Afterthought!" in this journal, show that others so understood. But a man who is doing as good work as Mr. Simpson may easily be forgiven for failing in a single case to make himself rightly understood.

Deficiencies of Bee-Books.—Every now and again the novice makes the charge against his text-book that it lacks the very thing he most wants to know. The text-book on bee-culture that is perfect is yet to be written, and the probability is that it will never be written. Yet it is doubtful that more truth about bee-keeping could well be gotten into the same space. It must be remembered that no matter how full and complete a bee-book may be within the limit of a certain number of pages, there can not of necessity be full minute upon all points that may arise. New complications will always be arising that will raise questions which can only be answered by some one of experience, and for the very purpose of answering such questions a department in the American Bee Journal and in some other journals is constantly maintained. The readers of this journal need never hesitate to make free use of the department of "Questions and Answers." Especially are questions allowed, and even solicited, from our regular subscribers who have made careful study of the text-books.

Study carefully your text-book, and become familiar with it; for the question department is not intended to take the place of the text-book, and after you are familiar with the contents of any good work on bee-culture, you will ask intelligently questions whose answers will be useful to many others. But don't ask too much of the text-books, and don't expect a study of them ever to leave you without some question that needs answering.

Warming Combs.—When Wm. McEvoy gives additional combs of honey in the spring, he takes the precaution to have these combs warmed before being put in the hive, by keeping them in a very warm room until they are warmed clear through, as he relates in the Bee-Keepers' Review. If one stops to think, this will appear a rational proceeding. The combs in the hive, whether full or empty, will be of about the same temperature as the cluster of bees, so far as the combs included in the cluster or touching the sides of cluster. Now suppose the cluster is divided to receive a fresh comb of honey, or even if it be placed close up against the cluster, it is easy to see that the bees would be thereby chilled, and perhaps serious damage done. Mr. McEvoy is doing a wise and paying thing to warm the combs that he gives. Of course these combs are given in the evening, and then there will be little fear of robbing.
tars (vetch) from the wheat without destroying the latter. Vetch is usually sown with timothy or some other tall-growing plant which aids it to stand up.

If any of our readers know vetch to be a nectar-yielder in their locality, we should be pleased to have it reported; also time of sowing, and how to grow it successfully.

**FUMIGATING COMBS WITH BISULPHIDE OF CARBON.**

"How soon may combs that have been fumigated with bisulphide of carbon be given to bees without killing the bees?"

Mr. Benton—I have frequently used bisulphide of carbon and used the combs an hour after that; but if you put a whole colony of bees in, there would be a chance of killing the bees. I don't think there is any danger in a few hours. It evaporates very rapidly.

Mr. Abbott—I don't think that bisulphide of carbon would affect anything in 3 minutes after if it is not confined. Bisulphide of carbon won't affect anything if it is not confined; and if you can pour all the bisulphide you please on a comb in the open air and it will all be gone in three minutes, and I don't see how you could kill the bees without it being confined.

Mr. Benton—The odor would be disagreeable; I don't think it would kill them.

Mr. Abbott—I use it for keeping the moth from eating up the paste that I paste my papers with. I pour a little in a saucer and in a few minutes the moths are all killed. I do not hesitate to open the can and breathe it, but if it was confined I wouldn't want to stay there.

Dr. Miller—I would like to ask this question: Does bisulphide of carbon kill the eggs of the bee-moth?

Mr. Benton—I think it does. I never have had them develop in combs that were thoroughly subjected to bisulphide of carbon. I would stack up the combs side by side in a heap of bisulphide in there and let it stand several days; some of those combs that had stood two or three months in hot weather; there were eggs there I know because other combs developed.

Dr. Mason—I had some extracting-combs that I noticed the worms working in, and I put the combs up and put a teaspoonful of bisulphide of carbon in a dish on top of the frames, and in two or three days when I examined them there wasn't a sign of any worms but dead ones.

Dr. Miller—We have been using sulphur, and now we are told bisulphide of carbon is better, and we want to know about how much better. Now, in using sulphur, if the combs have in them the larvae of the bee-moth, I wish Mr. Benton would tell us a single word that we can do with them. As far as these worms, when they have attained any size—say if they are half an inch or an inch long—you may sulphur them so thoroughly that you will turn them all green, and those big fellows will still be alive and happy after they come out again. Now, will the bisulphide kill those old chaps?

Dr. Mason—It will kill every one of them. We have tested this that summer that had wormy combs in it, and when I discovered it they were great big fellows, and in an hour's time after using the bisulphide every one of them was dead.

Mr. Barb—I would like to ask Mr. Benton whether he applies that bisulphide above or below.

Mr. Benton—On the top, because it is heavier than the atmosphere. I put an empty super there and set a little tin can in there—possibly half a pint, or a small can, for quite a stack of hives. Mr. Abbott—Did I understand Dr. Miller to say that sulphur gas will not kill the big worms? I have never seen anything that I could not kill by sulphur gas. Seriously, I think you are laying down a proposition that seems to be contrary to all scientific investigation. If there is anything that threatens the life of a live in sulphur gas, I have yet to see it. I used to be in the patent medicine business, and we had a vat in which if you had hung anything from an elegant down to a mosquito it would kill it.

Dr. Miller—I don't know of any way to get it sufficiently strong by ordinary means.

Case—My business down in Ontario County a few years ago was raising hops. I found a colony of bees one time, when I was drying hops, that the worms had destroyed, and I says, "Now I have a chance to fix you." So I took the combs that were a mass of worms, and put them into a small sack and put them into that in which there was perhaps 20 feet square, where we burn all the way from 25 to 50 pounds of brimstone in about three or four hours, and I took pains to hang them on the wall with a stick so that I could get them up as near as possible to the ceiling to get the benefit of the brimstone; and I left them there all night and burned the brimstone myself, and when I took them out in the morning the worms were alive.

Mr. Abbott—Was that kiln air-tight? Mr. Miller—There was an air-tight bottom, but the air is full of brimstone.

Mr. Hutchinson—Has any one used gasoline for killing moth-larva? Mr. Root—We have used it for killing ants. We made holes in the nests and poured gasoline in instead of bisulphide of carbon to kill ants.

The following is a letter made in an obscure (?) journal, (I think it is called Gleanings,) the statement was made that it had been used to kill the larvae of the bee-moth, and in connection with that the editor stated that he had used it to kill ants.

**Weekly Budget.**

Mr. R. A. Henderson's Apary is shown on our first page this week. He is in this (Cook) county. He began last spring with 11 colonies, and he says, "With the American Bee Journal and A B C of Bee-Culture as my guide, I increased to 45 colonies, by rearing and buying queens; and took off 1500 nice, finished sections." Mr. Henderson succeeds because he puts sense and enthusiasm into his work with bees. Of course, his good location makes up the rest, as nothing else could replace the lack of that.

Mr. A. L. Booten, of the A. J. Root Co., is soon to visit the West Indies—Barbadoes, Jamaica, Cuba, Trinidad, etc. Also Rambler (John H. Martin) is to "trip it" through Cuba with bicycle, camera, etc. There is no more enterprising concern on the continent than the publishers of Gleanings in Bee-Culture. And that elegant periodical shows the wonderful amount of work and expense constantly bestowed upon it. It richly deserves all the success with which it is meeting these autumnal days.

Mrs. Clara West Evans, one of the subscribers of the American Bee Journal, has been nominated as a candidate for superintendent of schools for Allamakee Co., Iowa. The local newspaper where she lives, besides giving an excellent picture of the nominee, has this to say among other endorsements:

"Mrs. Evans has the health, energy and ability which fit her for the duties of superintendency of schools, and we selected her best to meet the requirements of that office. As a business woman she is thorough, honest and reliable. After the death of her husband, three years ago, she assumed the management of his business, and by reason of study and close application, ranks to-day as one of the most successful apiarists in the State of Iowa. She has held various offices of trust and responsibility in church and lodge wherever residing."

Some people don't believe in women going into politics. Neither do we—in the kind of politics most in evidence to-day. But some day politics will be cleaner. It would be cleaner now if only men and women of the stamp of Mrs. Evans were allowed to have influence. A woman who in her own industrial and social life has more manhood and womanhood in our officials—less party blindness and more righteousness in the voters.
Dr. Mason—Will the sulphur fumes kill the eggs?

Dr. No, sir.

Dr. Mason—Well, the bisulphide will, and there is no sense in using sulphur when you can get the bisulphide.

Now I pile up the hives as high as I can reach, eight or nine I don’t think I poured over two teaspoonsful in, and it killed every worm.

W. J. Craig, of Ontario—I have been much interested in experiments with the bisulphide, and have piled the hives up in the same way, but I found that the eggs developed into a grub inside of a day or two. But I have piles of them.

At the same time, when I used the drug in an air-tight vessel it killed the grubs and destroyed the vitality of the eggs as well, but with piling the hives up I find that only the grubs were destroyed.

Mr. Benton—Of course, it would be absolutely air-tight.

Mr. Craig—I am sure that I used two ounces of the liquid to ten supers, and I put it top and bottom.

Pres. Root—Then you probably had only one ounce on the top, if you divided the amount as a rule? I mean as a large margin. Would it be sufficiently, would it, Mr. Benton?

Mr. Benton—I think it would be, if of good quality.

Mr. Craig—We have found a good deal of difference in the quality of the bisulphide. Sometimes we have had it good and sometimes bad.

Mr. Mason—I have been able to state that it is extremely explosive, and if this was used in a room one should never go into the room with a lighted lamp, or candle, or pipe, or any fire whatever, for there is very little with great caution. I called attention to it in a publication of the Department of Agriculture about five or six years ago. I would like to know whether it had been mentioned before for this purpose.

Pres. Root—I don’t remember seeing any mention of it.

On motion the convention adjourned until 9 a.m. the next day.

SECOND DAY—WEDNESDAY FORENOON.

The meeting was called to order by Pres. Root at 9 o’clock.

ANNUAL PROCEEDINGS IN PAMPHLET FORM.

"Should the proceedings of the National Bee-Keepers Association be published annually in pamphlet form for distribution to its members?"

Mr. Hershiser—I feel very much interested in the work of the Association and the extension of its membership, for the reason that in order to carry out its aims it is necessary to have a fair and reliable publication available on hand to use when necessity requires.

In order to get members it is necessary to show them that they get something out of it. Most everybody when approached to join an association like this, the question immediately occurs to them, What is there in it for me? Now, there are a great many bee-keepers in this country and in others that has been members of the Association, but they are not members simply because they do not see that they are going to get anything out of it. They don’t expect it to be prosecuted for keeping bees. The chances are very remote for people living in country districts to be prosecuted; it is only in the case of some difficulty arising between neighbors. Now, if you could give a bee-keeper the idea of getting something out of it, it is very much easier to get him to join the Association; and anticipating that these proceedings would be published in pamphlet form, I have induced seven or eight people to join the Association with the idea that they were going to get something valuable from it. As far as I can see, the question as to the advantage of bee-keeping by the different bee-keepers from the different parts of the country are very valuable if the bee-keepers can get them. I think that it would be a great advantage to have these proceedings published in pamphlet form, and every member to get a copy, and, if that is the case, I think that that is the best means of extending the membership and making the Association strong, and getting the two or three thousand members that so many of us ardently desire.

Franklin Wilcox, of Wisconsin—In addition to what has just been said, I might say that I think that every member of the Association that pays his dues is entitled to a copy of all the proceedings of the Association. He should have it in some form. The question as to whether it should be published in pamphlet form is the question for the members to solve. It is published, as here-tofore, in the American Bee Journal, or any other journal, and each member of the Association furnished with a copy of that journal. Whether a subscriber or not, it covers all the requirements, in my mind, and would save some expense. The expense of publishing it in pamphlet form is more.

Mr. Hershiser—I would say in answer to the question of expense, that it is for that reason we want to go to the expense. If it is unfavorable to go to that expense, then we want to go to that expense.

Pres. Root—As I understand, the American Bee Journal containing the copy of the report has here-tofore been sent to every member.

Mr. Wilcox—That covers all the requirements, as far as I can see.

C. J. Baldrige, of New York—Last year I didn’t get the American Bee Journal.

George W. York, of Illinois—I think last year I offered to send all the copies of the Annual Proceedings and containing the report upon receipt of 10 cents. Perhaps some of the members didn’t get notice of it.

Mr. Hershiser—I think that would cover all—ten cents—and have it published in the American Bee Journal; and those who aren’t members could get it for 10 cents.

Mr. Wilcox—I had no idea when I made the offer that the proceedings would run through so many numbers. I wouldn’t care to make such an agreement again, but I might say that I agree with Mr. Hershiser, that it ought to be published in pamphlet form, and I know that the expense would not be any more than what I have been paying—perhaps it is much higher. It is much more pleasant to have the pamphlet and have the proceedings sent to each member. And, Mr. Hershiser, I think that the officers of this Association should publish the pamphlet, and charge 10 cents for each copy, and let the Association pay the printing expenses of that pamphlet, and charge the members 10 cents for each copy, and let the Association pay the printing expenses of that pamphlet, and charge the members 10 cents for each copy. I think that the proceedings of this Association are of sufficient interest to the members to have them published in pamphlet form, and each member should pay 10 cents for each pamphlet.

Mr. Mason—It is not a question of expense.

Mr. Hershiser—I think that the officers of this Association should publish the pamphlet, and charge 10 cents for each copy, and let the Association pay the printing expenses of that pamphlet, and charge the members 10 cents for each copy. I think that the proceedings of this Association are of sufficient interest to the members to have them published in pamphlet form, and each member should pay 10 cents for each pamphlet.

Mr. Abbott—This matter is subject to the discussion of the Board of Directors.

Mr. Mason—I may say that heretofore the Association has shared the expense of the stenographer with the American Bee Journal. The Philadelphia convention the bill was paid by Mr. York alone, and this year also he pays the stenographer. If the Association expects to get any of it out of the general cause of bee-keeping by paying their dollars.

Pres. Root—Of course, you understand that the discussion is advisory for the Board of Directors.

Mr. Mason—I may say that heretofore the Association has shared the expense of the stenographer with the American Bee Journal. I believe that such reports give tone and character to a meeting, and I think that in the time as though we were a kind of Cheap John affair, simply because we trusted the papers to circulate our literature and be paid alone. I have intimated as much to the general manager, but he and some of the Board of Directors seem to think that a Cheap John arrangement is just as good and cheap as any arrangement. There are some beekeepers who are keeping bees according to the old methods that prevailed 50 years ago, and 50 years ago we would not have needed any report of that kind in order to promulgate our interests, but the time has come now when we need a report, bound and separate, and distinct from any paper, any journal or anything else, and as a newspaper man I know that there can be enough advertising put into the back page of the Journal necessary, to pay for issuing the pamphlet; in fact, I am not so sure but I can find an advertising solicitor who will make the solicitation and get the sale for the sake of the advertising that he can get in it. I understand that we are near the thousand mark in membership, and we are going to begin the next edition, and if you have not given your dollar to help pass this thousand mark, we would be glad to have you do it now. I am glad that this matter has been brought up. We can get character and influence outside of the bee-keeping fraternity by having a thing of this kind. For instance, we can get famous men who are driving that honey. I want to sit down and write to him with regard to it. I say to him: "Dear Mr. Smith, I mail you today under another cover a copy of the Proceedings of the last National Bee-Keepers Association. It includes the names of officers, and the constitution, and explains our aim and purpose, and shows how they can be done. Now, don’t want to make any warfare on your business, but you will notice that we are a thousand strong, and unless you stop your advertising we shall have to bring the law to bear.
on you." A business man sometimes is known by a letter-head. If I get a letter from a business house on a Cheap John piece of paper I generally chuck it up and go no further attention to it. But if I get a neat letter, printed nicely, on good paper, written in good style, proposing something in a business manner, I say, 'there is a firm that stands for something,' and I write to them. These things tell in the world, and we want to use the things that are used by others also, spending of a few dollars for a report will do more, in my opinion, to help the bee-keepers of the United States than anything else we can possibly do. The bee-keepers are not the only people who are interested in the arguments presented now, as well as some other things, that the use of such a report might be an excellent investment; that, even if it does cost something, it will bring in more than goes out, and on that same line I endorse the thought that we don't want it on the Cheap John line. We have taken a stand and we shouldn't get a clean report. I believe if we are going to go on the dignity, we would better keep it clear of everything that isn't a public notice.

Dr. Mason—Mr. York informs me that a thousand copies of the proceedings can be published in pamphlet form, and a copy mailed to each member for 50 cents. N. D. West, of New York—If we get the pamphlets printed, would it not be a good plan to have more printed than our present edition? We might obtain them for a certain stated price, the amount to be thrown into the treasury to help maintain this organization? Also, is it possible the report is in pamphlet form, we would expect it and want it in the American Bee Journal just the same. In regard to the advertising in the back part of the book, I do not see that that would materially injure our pamphlet, if it was gotten up in a neat and attractive shape. It is necessary for us to save all advertising in this form. In regard to these things, and yet we do not want to do anything that would be any injury or injustice to the pamphlet itself; but I am looking forward to a time today that would like a pamphlet that belong to this Association, and which might be an encouragement to get others to join the Association later on.

Mr. Hershiser—I know that this convention recommended the Board of Directors to print the proceedings of this convention in pamphlet form, and to issue a sufficient number to supply each member and, I think, at a reasonable number as they may think best.

Dr. Miller—I second that motion.

The motion was carried.

Mr. President: The President of the Buffalo Society of Natural Sciences, was then introduced to the convention, and gave the following address of welcome:

Dr. Smith's Address of Welcome.

Mr. President. Ladies and Gentlemen:—I trust you will continue to remember the generous and noble disposer, who adulterates honey, but the one who is doing all he can for the advancement of information and of science in the city of Buffalo. It was with very great pleasure that we received information from the National Bee-Keepers' Association that they would meet in Buffalo, as we desired very much to entertain this organization, and hence we wish to state to you that these rooms are yours during your stay here. We have made a plan and a list of several other rooms in connection therewith, in which your directors and committees may meet, and, of course, as can be seen by the roll, we would have you here stay agreeable and pleasant and we will be very happy to do.

Nearly 20 years ago the citizens of Buffalo subscribed nearly three quarters of a million dollars for the erection of this building. It was to be the home of the Public Library, of the Academy of Arts, of the Historical Society, and the Fine Arts. Since then the Fine Arts have outgrown the limits of the building, and a public-spirited citizen of Buffalo, Mr. Alforth, has provided them with a very beautiful building, which you will notice as you enter the Pan-American grounds. This will be the headquarters of the Fine Arts. Their board of directors has been taken by the Public Library, which was formerly supported entirely by private subscription and membership, but with the growth of it has grown so great that the city has fathered it, and now devotes nearly $75,000 per year for its maintenance. The ground upon which this building stands was given to the city.

Of course, this is simply an idea of what the spirit of the citizens of Buffalo is in regard to educational and scientific work. Everything is being done by the city for the finer arts, and further the work of such organizations as this. The presence of the bee-keepers is simply another step in the interest that is felt in this city in the subject of bees. Nearly ten years ago one of our most lovely members, the Hon. David F. Day, a man of great learning and of ability, a botanist, perhaps that we can in the United States and in the world, suggested that it would be a very interesting and valuable thing if the subject of the honey-bee was studied more deeply as nearly to the understanding of the public.

The matter was canvassed by the board of directors of the Society of Natural Sciences, and that possibly the general public was too busy with other affairs, and had lost interest in such matters, and that it would be better to begin with the young. After considerable consideration, the question of giving an exhibition, in these rooms, of the honey-bee, to the children of the advanced grades in the elementary schools was taken up.

The Society made the offer to the Superintendent of Education, and to the Board of Education, and it was very agreeable to both.

We had long known Mr. Sleeper, who was familiar with the bee from A to Z. I entered into correspondence with him, suggesting that he bring here some of the public demonstration to these children of the different classes, answer questions, and give them an idea of the interest, the usefulness, the marvellous instinct of the honey-bee. Mr. Sleeper very kindly accepted this invitation, and came on here in winter and these rooms were thronged with the pupils of the public schools in the 8th and 9th grades, with special classes from the high school, and with classes from the various private schools. At that time we had in the city also a school of pedagogy in which advanced teachers were given courses. This school also agreed to repeat, and I have exhibited very carefully. The result was a profound success of the enterprise. I don't think that any departure made, Mr. Smith and Superintendents of Sciences, brought it more valuable returns in the way of interest of the public in its work. We extended that system of educational work, and we sent, for instance, collections of Indian relics, of animals, of birds. We have classes here from the schools that meet to study birds. But it began with the honey-bee. It was a case where the opening of the bee opened the ball, and our department in this line is the most successful of the branches of the Society of Natural Sciences.

Mr. Sleeper, I may say, almost made himself a martyr to this cause of science, in that one of the very coldest days he was due here to lecture at the Public Library, and at that time the station and in getting them in here he was taken with pneumonia, and lay at death's door for some time. It was a case of necessity that he did not, and we had then to call upon Mr. Hershiser, who very kindly offered to continue the course of lectures, owing to the illness of Mr. Sleeper. This department will steadily be continued.

You see, therefore, that we owe a great debt to the bee-keepers, and in inviting you among us, and being able to offer you some little entertainment—a place to meet, or some little thing we can, I give you an idea of the debt of gratitude we owe to the bee-keepers. I have also given you a little suggestion of what is being done here, and I have in my course a study of the honey-bee. Of what great interest the study of this subject is to the general public, and I hope to see the time when every school shall have in its course a study of the honey-bee, with a practical demonstration. It is a wonderful creature and the subject is fraught with the greatest scientific interest in all its details.

The diseases of the honey-bee are something that every scientific views with the greatest interest, and you gentlemen with practical knowledge of those subjects can do so much to advance the scientific inquiry in regard to the diseases that are common to the lower orders of insect life. Of course, the same general line of diseases to kill the honey-bee kill many of the insects that are destructive to vegetation, and a whole world of inquiry is opened up by the study of this one little insect creature, which is a part of the animal kingdom. I wish to thank you most kindly for your attention, and again I wish to welcome you most heartily to our rooms.

(Continued next week.)

Requeening Every Year is coming more in favor all the time with Adrian Getsa, Bee-Keeper at Review. All bee-keepers quite commonly prefer to leave to the bees the task of requening. With young queens he has fewer drones and less swarming. But some will object that annual requening gives less chance for thorough establishment of a reputation for queens to breed from.
No. 1. APICULTURE AS A BUSINESS.  
Plant-Growth Conditions in the Arid and Irrigated Regions.

BY R. C. AKIN.

FOR two years the general honey crop has been rather limited. The great forage-plant of the West—alfalfa—is not much grown outside of the irrigated districts. Drouths to the extent of 10 years are not uncommon and the main source of the East—white clover—and the Eastern short crop has made a demand for honey from the irrigated districts.

I observe that the people are prone to jump at conclusions, both in general and in particular; and, regarding honey-production and apiculture as a source of a living income, an analytical discussion dealing with facts and figures touching the industry as a business seems timely and much needed. Among the things that lead me to this discussion, are the rash ventures made by inexperienced ones going into the business without due investigation and consideration. But, how are we to reach these people? My thoughts through bee-paper channels will entirely miss the most of these rash enthusiasts, for they do not read such literature, many of them possibly but little of any kind, especially of a scientific nature. However, many now in the business are to be esteemed, and who would exceed our liars, some who are planning to extend their business, or, perhaps, to change locations, may be benefited by a discussion such as I am about to undertake.

ALFALFA.

Two things that need to be understood better are sources of honey and the dependence to be placed in them. There is a great diversity about the nature of these. Westerners share in it—that the two main sources of the irrigated districts—alfalfa and sweet clover—are a certain supply, never failing. This is one of the things that must be considered in the business calculations. If an annual yield of a given number of pounds per colony can be obtained, we have somewhat to build upon.

When I came to this place the farmers here were making an effort to grow red clover, and many fields of it were to be found all over this district, although alfalfa was the main crop. Their two efforts have proved quite a crop of red clover honey, then the clover ceased to exist. So far as I have observed, any and all the clovers do exceedingly well. I have never seen anywhere such immense growth and blossom. While clover then and now is the tap-root, it is decidedly a clover soil, white and red clover will never succeed in general. Our climate is so dry—that so many months in the late summer, fall and winter without sufficient rain to keep the ground moist—that the clovers do not get started or, if started, are soon killed out by drought. Irrigating water begins to get scarce in August, and in September and October we can scarcely get any. Just now—October—there is but a very limited water supply. I get many inquiries from the East about our country—this answers many.

In winter and spring—particularly late winter and early spring—is when most of the snows fall upon the mountains. When snows fall upon the Precipitation in the Missouri and Mississippi valleys, we are having ours, too, but ours mostly falls upon the mountains. The general trend of air currents is from west to east, and the high, cold mountain tops condense and precipitate moisture from the Pacific; thus the moisture is, as it were, strained out of the air before it gets to us, hence the country at and near the mountains on the east is a dry one.

Beginning at the "foot-hills" (first hills of the mountains, and I use distances on a magnificient scale), is the dry or arid region. This arid region continues arid, and gradually changing to one of more humidity as distance increases from the mountains, until when the Missouri valley is reached, it is no longer arid. The Missouri species fall becomes sufficient to make farming a reasonable success. Precipitation varies as air currents vary because of high or low mountains and other physical arrangements of the country.

The reader will comprehend that in the spring, as the weather begins to warm, the accumulated snows begin to melt and flow out of Great Rockey mountain. The altitude of the "Rockies" and you will understand that spring up there is late. Comparatively little water gets down before April, the greater part coming in May and June. We depend upon spring rains to start the crops growing, and, by that, the clovers and alfalfa—on which the fat bee bees feed. Of course, there are other reasons, however, for for starting crops without irrigation, but not necessary to discuss them here.

Remembering, then, that there is but little water to apply the soil in early spring, rather from early fall till late spring, you will see how almost an impossibility it is for white and red clover, or any shallow-rooting plant, to live here. The red clover fields planted here 10 to 12 years ago are now winter-killed and there are none on hand.

Only such as send long, thick tap-roots deep into the ground, and such plants as by nature are fitted to withstand drouth, these only can survive here. As an illustration, buffalo grass will become almost perfectly dry, yet retains vitality and responds when moisture comes again.

These conditions necessarily limit our flora to such plants as are peculiar to arid districts, and the principal of these, aside from the California region, are alfalfa, sweet clover, and cleome. The former is grown of necessity, because the honey is desired, and clover cannot be grown here. Sweet clover is just in its element of soil and climate here, and while an unwelcome addition so far as the farmer is concerned, yet it flourishes along ditches and roadsides where it is not needed, and moistures, if it is not cultivated out. While sweet clover endures much dry weather when once started, it is not by nature an arid-region plant. It grows most luxuriously by ditches and water-courses, and around the bridges and wells, because the alkaline soil is its natural soil, and its long tap-root can reach deep to moisture, it makes quite a growth in quite dry soils, though depending upon rains to start the new plants. It is a biennial. Alfalfa is of the same nature as sweet clover, but will not stand quite so much moisture in the way of a wet, soggy soil. Alfalfa is a perennial, whereas the other clovers are more truly biennials, hence the former once established grows on and on indefinitely, roots becoming large to 20 feet long, penetrating almost straight down. Alfalfa never reaches its best until after the third year.

Now, while in some localities there is more or less bloom that gives a surplus honey, so far as the irrigated regions are concerned as a whole, we have but three sources of honey—alfalfa, sweet clover, and cleome. The first is the famed world over, the second is a common and well-known plant in all beedom—so far as its reputation goes—and the third is probably confined to the mountain regions, including all arid districts. Cleome is truly an arid-region plant, growing where neither alfalfa nor sweet clover will. Not one of these plants is absolutely sure as a honey-yielder. Each needs its peculiar conditions to make it succeed, both in making a growth, and in nectar-yielding. My own field of the three sources; first in importance is alfalfa, second sweet clover, and last cleome—this latter not in quantity to give a surplus with the great numbers of bees to work upon.

As to conditions necessary for the plants, I will briefly give my opinion, but consider this only as an opinion, for I am not certain. Alfalfa needs to be well irrigated, and have a rich, healthy growth, then bright, hot weather while growing. It does not mind drought. Alfalfa, or sweet clover is much the same as alfalfa, though to yield well I think it needs a more humid air, and probably less heat, showery weather seeming best. Cleome yields pollen in the morning, is visited by the bees before alfalfa is scarcely touched, and evidently does best with cool, moist weather. While cleome will grow almost from the dry, hard road, yet I believe it secretes best with rather cool weather and occasional showers. Not living in a region of great abundance of cleome, I am not so well acquainted with it.

I have harvested much alfalfa, also quite freely of sweet clover, and a little cleome. Because of irrigation keeping some fields of alfalfa in prime condition every year, we seldom fail to get more or less honey from these. It in no way requires paying for water, for until 12 years ago we have not taken at most more than six fair to good crops, and of these, generally speaking, I may say we were alfalfa, two red clover and two sweet clover. But, while two were almost exclusively alfalfa, four were mainly so,
Introducing Queen-Bees by the Improved Method.

BY W. W. M'Neal.

It devolves upon me to write farther of the method of introducing queen-bees, recently submitted for the benefit of the readers of the American Bee Journal, and which was referred to Wm. M. Whitney.

I wish to say that I have no ill feelings whatever towards my opponent; neither is it love for discussion that brings me before this intelligent audience of bee-keepers. I only desire to take issue here, and in many instances, on a practical principle involved which honey-producers cannot afford to ignore.

Mr. Whitney now professes to be very much surprised (see page 99) at my taking issue with him, and says all his statements are antagonizing one of the grandest truths which has been given to the bee-keeping world. If he knew the position he took was not "tenable," then what motive had Mr. Whitney in taking the position at all? If the assertion be true—"love, hatred, prejudice, and selfishness" are unknown qualities in the make-up of the honey-bee, how does Mr. W. harmonize this with his former statement that the honey-bee is "prompted by the highest type...of love and patriotism?"

This, however, is not the point directly at issue and I must not linger here. I did not "take seriously" the words of my esteemed fellow-bee-keeper, though it seems that he is in fact, to place a lower estimate upon his writings than I was wont to accord him.

Now, what I specially wish to ask of Mr. Whitney, and all who are interested in apiculture, is to try the method I give you for the safe and practical means of introducing a queen-bee. In the name of progress, I ask of you, at least, to try the plan and see if it is not good.

I have tested it and find that I can introduce a queen-bee safely into any colony where a queen-bee can be introduced by any other method; and, in many instances, more successfully than by any plan of caging. I know others can do what I have done if they pursue the same course. One does not need to be an "expert"; in fact, the system is practically self-sufficing in itself.

The fact that these teachings are not recorded in the pages of any of the recognized works on bee-culture does not signify that they should not be there. I hope no one of the readers of the American Bee Journal is so impractical as not to be able to recognize a good thing till it is written in some text-book.

Instead of throwing cold water on a principle that has real merit, why doesn't Mr. Whitney come out and do the practical thing, and advise the beginners against the folly of purchasing such valuable queens as he seems to have in mind? What use has a beginner with a queen so valuable that he cannot make use of her?

Cats with which queens may be exchanged, and the time thus gained, when time means honey, eventually stored by bees reared from eggs laid by the queen during the interval the adviser of the caging method would have had in his cage

When the queen of a strong colony is taken away and introduced into another by caging her, I believe that it will be safe to say that a week's time will be required for the queen to reach her former proficiency in egg-laying. Now, all this causes the new queen to appear at her worst at the very time when she should be in her best physical condition. The colony thereby becomes impatient from the inability of the strange queen to fill all the place of the one taken away, and shifts its hopes to the rapidly-developing larval queens; thus, in a measure, she becomes a prisoner awaiting execution by her younger rivals.

To show farther the utility of immediate introduction of the queen, let me relate that I have found no difficulty in thus introducing queens into colonies from which the old queen has not been removed. This is no "idle dream," and what I have done you can do.

Where a colony occupies two sets of combs, take the old queen and a frame or two of the brood and place them in the upper story over a queen-excluding honey-brood. Now close the hive and smoke the colony from the entrance while pounding lightly upon it to frighten the bees thoroughly. Do not use enough to drive out the bees, but a moderate smoking while pounding will eliminate them so efficiently that the stranger queen may be allowed to run right into the hive from the entrance; and she will occupy the lower apartment as wholly as if the former queen had been driven away.

These are facts, and I give them as freely as the air we breathe, because I want to help as I have been helped.

Suppose you do make one or two unsuccessful attempts, is that sufficient cause for you to cast the thought aside as being destructive to the best interests of both the bees and bee-keeper?

Let some one even yet not understand, I repeat in all simplicity: Have your stranger queen at hand when you take away the reigning one. Disturb the colony as little as possible while catching the old queen; when she is found, close the hive and smoke the colony from the entrance, pounding on the hive, of course, while doing this. Do not smoke or pound alternately, for two or three minutes only; then allow the new queen to run into the hive by holding the cage up close to the entrance so that she may not escape in the air. Send a puff or two of smoke into the hive, but don't pound on the hive any more. The object is to frighten the bees as much, and the queen as little, as possible. See?

Next, I want to let a good job alone for a few days and do not disturb the colony. A frightened queen is almost certain to run up against her doom, be it in her own hive or in the midst of stranger bees.

I cannot continually call your attention to these living truths; so again I ask that they be tested upon the earliest opportunity; test them thoroughly, and I know that they will stand with you as they have stood with me.

Scioto Co., Ohio.

Questions and Answers.

CONDUCTED BY DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—Editor.)

I have subscribed to the Bee Journal and invested in the "A B C of Bee Culture" in the hope of being able to answer my own questions, but, unfortunately, I find myself farther at sea than ever, from the fact that the experience of nearly every bee-keeper is directly at variance with that of every other, and even the directions given by the same apiculturist contradict themselves constantly.

For instance, my first instructions were, "Keep your colonies strong," so, having several small colonies, I commenced to look up some general directions. I came to "I would advise deferring the uniting of bees until we have several cold, rainy days in October;" but farther on I find, "Beware of having weak colonies to be united in the fall. Much safer to have them all united long before the cold weather begins," and I am at a loss what to do—"defer until winter," or "unite long before winter?"

Again, I intended to introduce an Italian queen, so I ordered one and got directions to "remove the old queen at least three days before introducing the new one," but I did this, but the queen was killed. So I ordered another, and read that the proper way to introduce a queen was to "get the old one out, thoroughly frighten the bees, and run in the new one before bees can really see the new queen," and this, and also failed. Now, should you wait three days or not wait at all? The advocate of each plan says he has succeeded with 99 out of 100. I have failed twice out of twice.
The trouble with bee-books seems to be that either they tell everything except what you want to know, or they presuppose you know all about it and merely add an intelligent sort of a summary. I am the author of one; if I may be allowed to express the idea, that it is a pleasure to answer your questions, and I may say to you that whenever you reach the point where you can answer all your own questions, you have a whole lot of it that I'd like to have you answer. But it is to be a secret between you and me that I don't know all about bees.

Now I'll see what can be done toward reconciling the apparent contradictions that seem to trouble you. Your no-colony rule, and if any of the four words in it should be emphasized, it should probably be the first, making it read "Keep your colonies strong." Now, if you keep all colonies strong there will be no need of long-range planning. Your bees will always be likely to have some colonies that are not strong. If you use the nucleus plan of building up colonies, of course they will be weak at the start, building up as the season progresses, and there will be none that fail to build up satisfactorily; some colonies will become queenless and weak; indeed, there are different ways in which good beekeepers may have, each year, colonies so weak that they should be disposed of. But you must try to prevent having weak colonies late. A plan of having strong colonies to be united in the fall. Better unite not later than August, while bees are gathering and not inclined to quarrel, and while brood-rearing and other work is going on, so that the united colonies will have plenty of settled bees to divide into one harmonious whole before cool weather comes.

"Much safer to have them all united long before winter comes." By the carelessness, ignorance, or, perhaps, of some entirely satisfactory reason, October may come, and you find you with some colonies so weak that they will stand a poor chance of getting through the winter. It doesn't do any good to say reproachfully that you ought to have been in August in the first place. Your question is what to do now. They are not gathering and so are inclined to be quarrelsome, and if united at a time when very active a good many may be killed. A few days' waiting will make no material difference, for everything is at a standstill; so I would advise deferring the uniting of bees until we have several cold, rainy days in October. Then the bees will be inclined to be somewhat dormant and little inclined to fight; and, besides, they will be more likely to cling to any nursery with which they may have been united from which they were taken. Now, don't you think I have made a pretty good job of reconciling what seemed to you contradictions?

If it comes to the matter of queen introduction, I'm afraid I can't satisfy you so well. All the different ways of introducing queens, with various modifications and adaptations, would make a book of itself; and constantly new plans are being given that are said to be infallible, which, upon further trial, are not found to be always sure. I know of only one way that may not fail one time in a hundred, or oftener. Take two or three combs of just emerging brood (no sealed brood, which would only die of starvation), close them in a hive with the new queen, that no strange bee can enter, keep the hive in a warm place if weather makes it necessary, and, after five or six days, open the hive on the stand which it is to occupy. You will see that there is no chance for the queen to be molested, for not a bee is present which has ever been fed on any other queen, and, of course, every worker born in the hive will be loyal to the queen present. Other plans have their exceptions. You tried two plans, each of which had succeeded 99 times in a hundred, but you have been unlucky on the one time in a hundred, or else there was some little thing in which you did not minutely follow out instructions. One plan may put the new queen in the hive at the time of removal, the other in the hive after several days; and one plan may be as successful as the other, providing the proper instructions for each are fully carried out.

In the summertime it is some comfort to you to know that you are not the only one who has made a failure. There are others. But as you gain experience your failures will become less in number. Yet, unless you do better than I have done, you will be satisfied occasionally in introducing a queen as long as you live.

The Afterthought.

The "Old Reliable" seen through New and Unreliable Glasses. By E. E. Hasty, Sta. B Rural, Toledo, O.

LONG TONGUES AND LONGEVITY.

Having duly "banged" the long tongues, I begin to think we must choose some big gun and bang him against "longevity." Peers like certain brethren approve the work of certain colonies in the yard and credit it to longevity, when they have never tried to know anything definite about it beyond their own imagination. Has any careful, scientific-minded bee ever published any set of experiments showing two side-and-side colonies as differing much in longevity? We may not find all bees rigidly alike in term of life, but at present there is too much possibility of it for such jumping at conclusions. Perhaps we ought fairly to consider longevity in a colony is really such a lack of constitutional health that a large percentage of the young bees emerge alive but worthless. Page 599.

Mr. Dantan an Exemplar Vacationist.

For bee-keepers on vacation bent, C. P. Dantan is an excellent exemplar. Go to some nice town which has not been spoiled by tourists. Page 537.

Editors and Correspondents that "Spat." And so our editors must not "spat" so much, but just follow Paddy W. T. S., and hit every head in sight. Page 508.

A Pace for Guessers.

Thank you, Comrade Miller, for setting a good pace in the matter of guesses. We don't agree to replace them with new ones in case they fail to give satisfaction. Page 602.

Setting Mulberry Cuttings in July.

Mulberry cuttings to be set in July, Dr. Peiró says. Some of us do dull as to think that all cuttings should be set in the spring, of course, and we would make a total failure of it, very likely—and then scold the man who said mulberries could be raised easily from cuttings. Page 605.

A New "Bee-Society."

I'm afraid that the bee has a life-membership in the Gothic name-up-and-be-abed till-I-noon Society—this in respect to accurate mathematics, and in respect to neatness, and possibly in respect to some other things. Page 605.

Bee-Escape in Corner vs. Center.

I am no authority at all on bee-escapes, but my conjecture is that escape in corner is a great improvement on escape in the center of the board. With a quiet mass of bees above and below, which feel in communication with other—why should they do anything special to change so satisfactory a situation? Looked at theoretically we should suppose that the main thing is to make them want to get easily credited as short-lived in a colony is really such a lack of constitutional health that a large percentage of the young bees emerge alive but worthless. Page 599.
FRAUDS, MUMBUGS AND SUPERSTITIONS.

Is there anything in this world of ours that is grander, and more delightful to the soul, than genuine truth, entire absence of pretense, perfect ingenuity? On the other hand, is there aught that is more repellent, more discouraging in society, than fraud, humbug, superstition, all—or anything that maketh a lie? Among all these blessed fruits of our high development of science is that uneartihour frauds, revolting humbugs, and dotderones superstitions. She stamps her great, honest foot hard on whatever maketh a lie. How generously education touches her patrons to bless and to help. Is not one of her brightest objects that she so summarily dumps out of the mind its superstitions?

PATENT MEDICINES.

No doubt Holmes voiced a grand truth when he said that it would be a blessed thing if all the medicine of the world was dumped into the ocean; but, he added, it would be awful on the fish. As a learned and experienced physician, Holmes was entitled to speak. If he had but prefixed mediocrity was “patent” how much more of truth would have been uttered. It is fearful to note the great floods of advertisements of patent medicines that fill the pages of our newspapers. Millions of dollars are poured annually into the cesspool of the newspaper. It is awful to think of the amount of these vile compounds that are gulped down by a too trusting and suffering people. A synonym for patent medicine would be FRAUD, in capital letters. It is, indeed, for an absolute, unheralded forth as cures for all maladies? And are not all the tricks of the most artful, skillful and expert advertising agents employed to get these concoctions of the Evil One into the hands and stomachs of poor, suffering humanity? The poor, deluded victim of the patent-medicine vendor gulps down the atrocious potion, all ignorant both of disease and remedy. It seems strange that any one possessed of judgment and reason can ever be duped into patronage of the patent medicine chest. The discouraging feature is that sickness destroys sentiment and reason as they destroy her first legacy. Will we not all, in our various home circles, lift our loudest voice against this greatest fraud of the century?

THE MOON.

At our Farmers’ Institutes a very frequent question is asked, even in cultured Southern California, to-wit: Should the farmers observe the moon’s phases in planting and tilling? Of course, I always say plant when condition of soil, cultivation, and season of the year are right; and only watch the moon to see when to take evening rides with the “nude wife” or one’s best girl. And yet when I say this, I see many a head shake which speaks dissent. It is passing strange how any such superstition can hang on where once gets a foothold in one’s beliefs. This belief, so utterly void of any scientific basis in truth, I suppose comes down from our credulous forefathers, and from the fact that good tillers who practice watching the moon usually have good crops, as they surely would had they never heard of the moon, or noted whether they saw it over the right or left shoulder. It is good to talk all such absurdities over with the children and bury them in whose innocent laughter, for such burial is rarely followed with resurrection.

FRIDAY, AND THE RIGHT SHOULDER.

It seems impossible that in our day, when science shows the absolute absurdity of all such nonsense, that anyone would be disturbed by seeing the new moon over the left shoulder. Yet such is often the case. The person is usually advanced in years, for the science of today is hard on such tomfoolery. I have known not a few, some of them men of intelligence, who would never commence a new work or enterprise on Friday. They usually bluff to own the fact, and do not pretend to have any reason for the opinion; but superstition is usually so inwrought in their make-up, that they feel that it will be dangerous to disregard this old law. Such persons still dread ghosts, and are haunted by the hundred and one other nonsensical beliefs in signs and sayings that are utterly without foundation, and which, like belief in witchcraft, will soon by only known to history. It will be a good ridden. There are so many grand beliefs that take hold of our very lives and help us to better thought and nobler action, for us to waste thought or energy on all such baseless claptrap.

ROAD-SIDE TREES.

What is there in this world that is more worthy of admiration than a fine avenue of trees? There is one of peppers and another of blue-gums not far from Claremont. I always drive to these and through them when I have visitors. Often the visitors will exclaim, in surprised delight as we turn upon these lovely vistas, Can anything be finer than such avenues of trees? Ask the students who have enjoyed the clime of Cambridge and New Haven. Would not our home circles be philanthropists of the best kind, if they would undertake to secure such avenues along all our highways? I believe that if we combine utility and beauty, we show still better sense and judgment. So in the East, why not add to the honey-resources by planting great rows of line lindens, or the equally unobtrusive tulips? In the South the tulip and the Judas-tree are not only beautiful, but each comes each season with beautiful flowers laden with most delicious nectar. In California the eucalyptus is very handsome, a strong grower, stands drought well, and by a judicious selection of species we can have blossoms and nectar each month of the year. All have showy flowers, which, in some species, are very beautiful.

USE OF PROPER WORDS.

I have learned to have such respect for our good and genial friend, Mr. Hasty, that I rarely skip anything he writes, and as rarely find fault to criticise. So I was surprised that he suggests to let a dead use of words alone, as it will be useless to combat it. I say, Never. If a word is wrongly used, so as to mislead or work mischief, “go for it” with all the might, coat off, and shirt sleeves rolled up.

Yesterday our pastor spoke of coral insects. He might as well say “weedy birds,” or “hairy snakes.” Indeed, he would not have been as wide of the truth. Coral animals belong to a branch wholly distinct from that of insects. The old word “strain” rarely peeps up now in descriptions of honey. Why? Because it was a mischievous misnomer. We hit it hard blows, and, happily, knocked the very life out of it. “Larva” is correct. “Worm” means a thing wholly different. The added syllable with truth to stand on should not vex anyone. The recent bulletins regarding our beloved President did not confuse the terms digestion and assimilation. Of course not, the physicians know and practice the right use of words, and do they not show good sense?

I should like to hear from our good friend, Dr. Miller, on this point.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.
REVERSIBLE WALL MAP

OF THE

UNITED STATES AND WORLD,

WITH SPECIAL INSET MAPS OF

China, Cuba, Porto Rico, The Philippines, Hawaii, and Alaska,

Especially prepared to meet the demand for a first-class map that will give a quick, general idea of location of events the world over, and particularly to the United States and our territorial possessions. Very useful in every Home and Office.

66 x 46 INCHES IN SIZE.

ELEVEN BEAUTIFUL COLORS.

Best and Most Necessary Map Ever Issued.

No Home or Business House should be without it.

The Plates

are works of art. The engraving is plain, bold, and decisive. The color work is elegantly contrasted, but not gaudy.

Perfection and Artistic Elegance

a salient feature of this map not approached by any similar publication.

Photograph of the World

The 1900 Census

of the largest American Cities is given.

One side shows a grand map of our great country, with counties, railroads, towns, rivers, etc., correctly located. The other side shows an equally good map of the world. Statistics on the population, cities, counties, rivers, mountains, products, business, etc., a veritable photograph of the UNITED STATES AND WORLD.

The map is printed on heavy map paper and is mounted on stiff cards ready to hang. Edges are bound with tape.

1901 EDITION. Every reader should consult it every day. The plates show all the new railroad lines and extensions, county changes, etc. Special attention is given to the topography of the country; all the principal rivers and lakes, mountain ranges and peaks are plainly indicated. The leading cities and towns are shown, special attention being given to those along lines of railroads. The Canadian section of the map gives the provinces of Ontario, Manitoba, and British Columbia, with nearly all of Quebec and New Brunswick, the county divisions being clearly marked. The Southern portion of the map includes the Northern States of the Republic of Mexico, and the Bahamas Islands.

On the reverse side is the Library Map of the World. The largest and most accurate map on Mercator's Projection ever produced. The political divisions are correctly defined and beautifully outlined in colors. The ocean currents are clearly shown and named. Ocean steamship lines with distances between important ports are given. A marginal index of letters and figures enables one easily to locate every country in the world. A series of short articles in alphabetical order is printed around the border of this map in large, clear type, containing valuable information concerning agricultural, mining, and manufacturing statistics, also the value of imports and exports in dollars.

The area, population, form of government, and chief executive of every country in the world is given up to date, also the names of the capitals and their population. The Inset Maps are elegantly engraved and printed in colors. They are placed in convenient positions around the United States map and will be invaluable to every person desiring a plain understanding of our possessions. An inset map of China on the World side of map adds to its value.

Two maps on one sheet, all for only $1.50, sent by mail or prepaid express; or we will forward it free as a premium for sending us Three New Subscribers at $1.00 each; or for $2.00 we will send the Map and the American Bee Journal for one year.

Address,

GEORGE W. YORK & CO.,

Great Combination Subscription Offers.

Combination and concentration in business are the magic watchwords of the age in which we live. Why should it not be applied to the matter of subscriptions to magazines and periodical literature in general? We believe it is a wise move, especially when it is in the line of economy for the reading public. Now, if we can be the means of saving our subscribers several dollars a year on their reading matter, and at the same time help them to the best literature published to-day, we shall feel that we are doing a good thing, indeed.

We have entered into an arrangement whereby we can furnish the following excellent periodicals at greatly reduced prices:

<table>
<thead>
<tr>
<th>Magazine</th>
<th>Regular Price</th>
<th>The Dollar Papers</th>
<th>Regular Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>Review of Reviews</td>
<td>$2.50</td>
<td>Cosmopolitan Magazine</td>
<td>$1.00</td>
</tr>
<tr>
<td>Current Literature</td>
<td>$3.00</td>
<td>Frank Leslie's Popular Monthly</td>
<td>$1.00</td>
</tr>
<tr>
<td>New England Magazine</td>
<td>$3.00</td>
<td>The Household</td>
<td>$1.00</td>
</tr>
<tr>
<td>Leslie's Weekly</td>
<td>$3.00</td>
<td>Good Housekeeping</td>
<td>$1.00</td>
</tr>
<tr>
<td>North American Review</td>
<td>$5.00</td>
<td>Success</td>
<td>$1.00</td>
</tr>
</tbody>
</table>

P.S. Please notice that in all combinations Success and the American Bee Journal must be included.

Here is our List of Liberal Offers:

American Bee Journal and Success

If a renewal subscription is wanted for the Review of Reviews, Current Literature, or the North American Review, add $1.00 for each renewal subscription to the combination prices named above. On all the other combinations a renewal counts the same as a new subscription.

2. No foreign subscribers can take advantage of these combination offers.

We shall be pleased to have our readers examine carefully the above list, and send us their subscriptions.

Garden of Eden Was Irrigated.

When God made man and appointed him His most perfect condition He placed him on a piece of land watered by irrigation. Farming by irrigation still remains the most scientific and successful. With control of the water-supply the element of chance is completely eliminated, crops are sure, larger, of better quality and commanded higher prices. The most successful and profitable farms in the United States are irrigated, 50 bu. of wheat, 100 bu. of oats, 300 bu. of potatoes, 5 tons of alfalfa per acre per year are regularly produced.

UNDER THE WILSON PLAN

such farms can be had for little money on easy terms, possessing the requisite of Abundance of Water, Rich Soil, Home Markets, Good Society.

We share profits with those who can advance cash for land. Profits large; no risk.

Address for Bulletin giving full detailed information,

Homestead Land and Irrigation Company,

JAS. W. WILSON, Manager.

Better Report This Year.

I have a better report for the season of 1901 than for 1899 and 1898. The bees came through in very poor shape, short of stores and bees, half of the colonies with practically nothing; but they built up in June nicely, making up my loss in the spring by working about 30 pounds of surplus honey, spring count; and all hives were well filled for winter, with good honey; and nearly all colonies had young queens. C. H. CHITTENDEN.

Middlesex Co., Conn., Oct. 16.

Honey a Light Yield.

The season here was good until the drought set in July 10, when the excessive hot weather cut the flow short. The dryness of the air has caused the honey to be of heavy body and low quality. I started with 18 good colonies in the spring, increased to 24, and have taken off 540 pounds of comb honey—about 30 pounds to the colony. It is a rather light yield, a little above an average with my neighbors. Bees are in good condition for winter. JOHN CLINE.

Lafayette Co., Wis., Oct. 23.

Crop Not as Good as Expected.

The honey crop is not as good as was expected by the bee-keepers of this section. With a late, wet spring the bees did not swarm very early, and, therefore, were not ready to catch the first honey-flow. However, the honey flows well, and in the last two weeks of the season, at least in some parts of Pennsylvania, Buckwheat honey was almost a failure this year. The weather at the time it was in bloom, a good sale for comb and extracted honey. Bees are in fine condition for winter.

W. H. HcMM.

Poor Year for Honey.

This has been a very poor year for honey on account of the drought, but I think most of the bees are well fixed for winter. I started with 8 colonies, spring count, and increased to 12. I have got about 27 pounds of honey this season. Our spring honey-flow lasted only about two weeks, then came the drought; but I think the fall flow will prove sufficient for wintering.

W. H. Ellis.

Calhoun Co., Iowa, Oct. 12.

Crop Nearly a Total Failure.

Through smelter smoke, drought, and grasshoppers the bee-industry in this county, as a rule, has been nearly a total failure. I have 56 colonies at Pleasant Green, where they have lived for three years, and have not done well, but this season, owing to the grasshoppers eating the corn off bare to the ground, I have not taken off a pound of honey. There are several hundred pounds lighter—perhaps 15 to 15 pounds to each colony less than they were last year.

No. 1 comb honey is worth $8.00 per case, and extracted is worth 6 to 7 cents a pound, according to quality. The Omaha report of Percey Bros., in the American Bee Journal, is a burlesque as far as Utah is concerned.

E. E. SLOVEST.

Salt Lake Co., Utah, Oct. 22.

The Honey Crop and Prices.

We note in the American Bee Journal of Sept. 29 some dealers quote Utah comb honey at 10 cents for No. 3, and 9 cents for No. 2. This is a mistake. We have this season a quarter of a crop of what it was last year to make case, pay, etc. Sharples Cream Separators. Book "Business Directory" at 25c. Winslow, W. Chester, Pa.

year, and prices have been from $2.65 to $2.95

for cases of 24 sections, which means 13 to 15 cents per pound.

Of extracted honey we have half a crop of what it was last year, and producers are hold-

ing firm at 6 cents. This, of course, is too high for Eastern markets.

Knowing what we do about the crop condi-

tion of comb honey in the Western States, and

what information we have gathered from the bee-papers, we consider comb honey good property this season.

VOGELER REED & PRODUCE CO.,
Salt Lake City, Utah, Oct. 11.

Dark Combs and Color of Honey.

"Dark old combs give to honey a darker color. This is the experience of some—others say. Why this difference of experience?"—Bee-keepers' Review. May there not be a difference as to careful observation? Will not the length of time the honey is in the comb also make a difference in color? Some keep a black comb with water, and immediately throw it out, and the water will be clear. Let it stand for several days and it will be like ink.—Gleanings in Bee-Culture.

"Reviewlets" from the Bee-keepers' Review.

Too many Irons in the fire, is a bad condition of things. I saw it illustrated in several instances during recent trip through Ontario. So many made excuses about the appearance of things, and of the way in which they were worked, and of how they were behind, and always driven with work, all because they had so much to do; as one man said, he was "tired out all of the time." For instance, Mr. McEvoy has an apiary of about 100 colonies, several acres of berries, and is inspector of apiaries for Ontario. All need his attention at the same time, and he was free to acknowledge that had he turned his attention to bees, years ago, his financial success would have been many times greater. Those men who had bees alone, and a lot of them, were making the most money with far less worry.

A Hiving-Box made from a cheese-box was one of the handy things that I found in the apiary of Jacob Alpnaugh, of Ontario. Two staples on the side of the box are for slipping in the end of a long pole, whereby to raise the box up under the cluster on the limb of a tree. The bottom of the box is covered with muslin. The cover is also of muslin, but it is fastened at only one edge, opposite the side where the staples are, and can be drawn over the top of the box by means of two strings passing over the edge of the box and down the pole. When then the warm to get down, the box is put upon the pole, the cover slipped back, the box raised up under the cluster. The comb gives a sharp jar by means of the pole. This causes the bees to drop into the box, when the cover is quickly drawn over, thus means of the string, making them close prisoners. The box, bees and all, may be slipped off the pole, and set to one side in the shade, where it may be left until the bee-keeper has leisure to

BEST EXTRACTED HONEY—FOR SALE ALL IN 60-POUND TIN CANS.

Alfalfa Honey ★ ★ This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who knows its value to our health at all can’t get enough of the Alfalfa extracted.

Prices of Alfalfa or Basswood Honey:
A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 8 cents per pound; four or more cans, 7½ cents per pound. Basswood Honey, ¼ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are boxed. This is all ABSOLUTELY PURE HONEY. The finest of their kinds produced in this country.

Read Dr. Miller's Testimony on Alfalfa Honey:
"I've just tasted the honey you sent, and it's prime. Thank you. I feel that I'm something of a heretic, to sell several thousand pounds of honey of my own production and to urge the selling of honey of others. It is imperative that people know to the honey of his own region, there's no denying the fact that for use in any kind of hot drink, where one prefers the more wholesome honey to sugar, the very excellent quality of alfalfa honey I have received from you is better suited than the honeys of more marked flavor, according to my taste."
McIlroy Co., Ill.

Order the Above Honey and then Sell it.
We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, order the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.
center of the frame to prevent any sagging of the top-bars. Mr. Miller likes a battery for imbedding the wires; the only objection being that he becomes too hot and the wax requires rework-

Find Queens without the tedious operation of picking them, in a bulb, at a cost, some sure, short-cut method would be very desirable. Honey and Bee Wax

MARKET QUOTATIONS.

CHICAGO, Oct. 10—There is a very good trade in the market today, and the demand for five cents per pound which will not grade No. 1 or fancy sells at from 130 to 140c; some small lots of fancy have brought more than 15c; light dark honey graded 126 to 128c; the dark honey of various grades ranges from 100 to 150c; the dark honey of exceptional quality sell well at 55 to 65c for white, according to quality and size; while white clover honey brings from 50 to 60c,

Cincinnati, Oct. 25.—The honey market is rather dull at present. Extracted honey is selling at from 66c to 68c per lb; white clover honey from 66c to 68c; white honey from 65c to 66c. CH. G. WEBER, & Co.

ALBANY, N. Y., Oct. 25.—Honey in good demand, at present the price is 65c to 68c per lb, according to quality and size.

OMAHA, Oct. 25.—New honey is coming in by express in small quantities from Iowa and Ohio, and selling at 70c to 72c per lb in case in a re-

Peytons Bros.

New York, Oct. 25.—New beemoney is coming in, and demand is pretty good, and sells at the following rates: Fancy clover—white, 70c per lb; No. 1, 65c; No. 2, 60c; No. 3, 55c.	

Peyton Bros. & CHANTLEY.

Detroit, Oct. 25.—White clover honey, 140 to 150c; No. 1, 130 to 140c; No. 2, 120 to 130c; No. 3, 110 to 120c; No. 4, 100 to 110c; No. 5, 90 to 100c. Extracted clover, white, 60c per lb. Bee wax, 25c per lb.

San Francisco, Oct. 16—White clover, 105 cents; black, 85 cents; dark, 60 to 80 cents. Extracted clover, white, 50 cents; black, 40 cents. Prices are ruling steady, with no very heavy spot offerings and a fair inquiry, more especially for extracted. A shipping vessel, clearing the past week for England, 70 per cent. of the cargo is clover and 30 per cent. of the clover are 140/145c; the demand being quite brisk, a firm market is anticipated. Inquiries for extracted are heavy, but the buyers still seem to have their ideas too low. In a small way 90 to 100c, prices after the holidays.

BEE-KEEPING LINE.

WE MAKE ONLY THE BEST.

Our Falcon Sections and New Process Foundation are ahead of everything, and cost no more than other makes. New Catalog and copy of this American Bee-Keeper free. Address, THE W. T. FALCONER MFG. CO., JAMESTOWN, N. Y.

W. M. GREDISH, East Nottingham, N. R., carries a full line of our goods at catalog prices. Order of him and save freight.

Please mention Bee Journal when writing.

River Forest Apiaries!

FILL ALL ORDERS
By Return Mail.

Italian Queens Warranted

Unquestioned, 75 cts.; Tested, $1.00; Select Tested, $1.50. Half dozen or larger lots as may be agreed on. Address, RIVER FOREST APRIARIES, RIVER FOREST, Oak Park Post-Office, 30 AIL Cook Co., ILL. Please mention Bee Journal when writing.

THE NICKEL PLATE ROAD
will sell tickets each Tuesday, Thursday and Saturday during October to Buffalo Pan-American Exposition and return, at $6.00, good in coaches, return limit 5 days from date of sale. Tickets with longer limit at slightly increased rates. Three through trains daily. Chicago Passenger Station, Van Buren St. and Pacific Avenue. City ticket office, 111 Adams St., Chicago, 36-41 A4T.

A New Bee-Keeper's Song—

"Buckwheat Cakes and Honey"

Words by EUGENE SECOR.
Music by GEORGE W. YORK.

This song was written specially for the Buffalo convention, and was sung there. It is written for organ or piano, as have been all the songs written for bee-keepers. Every home should have a copy of it, as well as a copy of

"THE HUM OF THE BEES in the APPLE-TREE BLOOM"

Written by EUGENE SECOR and DR. C. C. MILLER.

Prices—Either song will be mailed for 10 cents (stamps or silver), or both for only 15 cents. Or, for $1.00 strictly in advance payment of a year's subscription to the American Bee-Journal, we will mail both of these songs free, if asked for.

GEORGE W. YORK & CO.
144 & 146 Erie St., CHICAGO, ILL.

Please mention Bee Journal when writing advertisers.

24th Year Dadant's Foundation. 24th Year

We guarantee satisfaction. *** Why does it sell so well? ***

What more can anybody do? BEAUTY, PURITY, FIRMNESS, NO SADDING, NO LOSS.

PATENT WEED-PROCESS SHEETING.

Send name for our Catalog, Samples of Foundation and Veil Material. We sell the best Veils, cotton or silk.

BEE-KEEPERS' SUPPLIES OF ALL KINDS.

Very fine pure-bred BARRED PLYMOUTH ROCK Chickens and Eggs for sale at very low prices.

Langstroth on the Honey-Bee—Revised.
The classic in Bee-Culture—Price, $1.25, by mail.

Beeswax wanted at all times.

CHAS. DADANT & SON, Hamilton, Hancock Co., Ill.

Please mention Bee Journal when writing.

Texas Bee-Keepers.

We beg to announce the opening of a branch office and warehouse at 493 W. Houston St., San Antonio, Texas. Rates of transportation from Medina in less than car-load lots are high, and it takes a long time for a local shipment to reach Southern Texas points.

Low Freight and Quick Delivery—than San Antonio. It has four great railroads—the Southern Pacific R. R. east and West—the International and Great Northern R. R. from Laredo up through San Antonio and Central Texas, the San Antonio and Arkansas Pass R. R., and San Antonio and Gulf R. R. It also has the American, Wells-Fargo and Pacific Express Companies.

Our Managers. We have secured as managers Mr. Udo Toepferwein, formerly of Leon Springs, and Mr. A. Y. Walton, Jr., both of whom are well known to the bee-keepers of South and Central Texas. They are also thoroughly familiar with practical bee-keeping and all matters associated with it, and any orders sent to this branch will receive prompt, careful attention.

Our Catalog. To secure these two necessary advantages—low freight and quick delivery—and to be better prepared to serve the interests of our Texas friends, is our reason for establishing this new branch office. No other point in Southern Texas is better adapted to serve as a distributing point than San Antonio. It has four great railroads—the Southern Pacific R. R. east and West—the International and Great Northern R. R. from Laredo up through San Antonio and Central Texas, the San Antonio and Arkansas Pass R. R., and San Antonio and Gulf R. R. It also has the American, Wells-Fargo and Pacific Express Companies.

Our Goods. As usual our motto is to furnish the best goods of the most approved pattern. We do not undertake to compete in price with all manufacturers. Bee-keepers have learned that it does not pay to buy cheap supplies, for a saving of 10 cents on the first cost of a hive may be a loss of many times this amount by getting poorly made and ill-fitting material. Every year brings us many proofs that our policy of "the best goods" is a correct one.

Our Catalog. Very few changes in prices will be made in our new catalog, so do not delay your order, but send it at once. You will be allowed a refund if lower prices are made, and in case of higher prices ruling in the new catalog, if any, you will secure the benefit by ordering now. Catalog and estimates may be had by applying to the address given below.

Our Invitation. Whenever you visit San Antonio you are invited to call at our office and make it your headquarters. Here you will find a display of Apiarian Supplies not equaled elsewhere in Texas. You will also find on file the leading bee-journals to pass pleasantly your leisure time.

Spanish Catalog. Some of you may read Spanish, or have a bee-keeping friend who does. If so, call for our Spanish catalog. It's sent free.

FACTORY AND HOME OFFICE: THE A. I. ROOT CO., Medina, Ohio.

Branch Office: THE A. I. ROOT CO., San Antonio, Texas, 438 West Houston Street, TOEPFERWEIN & WALTON, Managers.

GEORGE W. YORK & CO. are headquarters for ROOT'S BEE-KEEPERS SUPPLIES in CHICAGO. Send to them for their Free Catalog.
TEXAS HORSEMINT—A PLANT THAT HAS LONGER FLOWER-TUBES THAN RED CLOVER.
(See page 706.)
Weekly Budget.

We (this time the "we" includes Mrs. York) had a splendid visit last week, for a day and two nights, at Dr. C. C. Miller's, in McHenry Co., Ill. We expect to have more to say about it later. Dr. Miller is well, and enjoying life better than most young men who are on the other side of 70.

Mr. Geo. W. Riner, of Lucas Co., Iowa, writes us that he expects to be present at the meeting of the American Bee-Keepers' Association, on Dec. 5. He will then be on his way to New York—his old home—where he commenced bee-keeping in 1868, six miles north of Auburn. Next spring he expects to go to Colorado with his 200 colonies of bees. Rev. Jasper—the colored preacher—said: "The sun do move," Surely, bee-keepers "do move," too. They are more and more going to locations where they "can keep more bees." Success to them all.

Mr. J. W. Ferree is the four-brood inspector for Los Angeles Co., Calif. "Rambler" has this to say about him, in gleanings in Bee-Culture:

"Mr. Ferree is a genial bachelor, a member of Mr. Bresee's church; will go a long way to serve a friend; generous every day in the week; polite and condescending to the ladies; always shows an even temper; and the mantle of four-brood inspector could not have fallen upon more worthy shoulders."

Mr. Ferree has inspected 148 apiaries, 830 colonies: 284 four-brood colonies. He estimates that there are 100 bee-keepers and 20,000 colonies in Los Angeles county. Mr. Ferree seems to be the right man in the right place.

The Apiary of J. M. Paxton, of Brooks Co., Ga., is shown on page 711. He commenced bee-keeping in 1899, buying an apiary of 29 colonies of Italian and black bees. In May he bought the bees and honey crop of about 1000 sections of comb honey. He had little or no experience in bee-keeping, but sent for the book, "A B C of Bee-Culture," and did fairly well the first year. The bees were kept about one-half mile from his home. He paid $150 cash for the bees and outfit, and sold about $230 worth of honey the first year. He moved the bees home the following winter, and lost five colonies, having 22, spring count. He increased them to 41, and sold $113.50 worth of honey that year, which was a very poor one for bees in that part of the country.

HORSEMINT—Monarda punctata. — The engraving of this honey-plant, shown on the first page, was kindly loaned to us by Gleanings in Bee-Culture, from which periodical we also take the following paragraph:

"Horsemint begins to bloom in May, sometimes a little later, June, depending on the rainfall of the season, and is always in flower in the spring. The honey is compared with that of the basswood of the North, on account of its peculiar strong flavor which it resembles; it is of light color; one of the best honey-plants of the South, and tremendous yields have been obtained. I have just gone out to procure some of the flowers, and send some to you herewith. Perhaps you remember what you said about a chance for long tongues who could be taking the shot at the horsemint on our porch. I have been interested in this question, and can not see how honey could ever get everything that is nectar out of those long tubes. What do you think of that? It Red clover not alone for long tongues."

Editor Root took the picture while in the South, and also wrote the above paragraph there.

PEARS IN CALIFORNIA. — Mr. B. S. Taylor, of Riverside Co., Calif., writing us Sept. 16, said:

"I enclose a small picture that will give some idea of how pears grow in California. The branch was taken from a small tree growing in my front yard. I think they are the Bartlett, but I am not certain. It is one limb, and there were 67 of them in the two clusters at the time photographed, though about 20 had previously fallen off."

Surely, California is a wonderful fruit country. We think we never saw such clusters of fruit growing anywhere as are shown in the picture. It wouldn't take long to pick a few bushels of them when growing so thick. (See page 714.)

Mr. John H. Martin (Rambler), of California, writing us Oct. 26, said:

"I am packing up and going to move over into Cuba to sow there through the winter. By so doing I secure a continuous honey-plant for the next four or five years. Field No. 1, in southern California, from April until July; Field No. 2, in central California, from July until October; Field No. 3, in Cuba, from October until April."

Rambler ought to be the sweetest rambling man in all the world—continuously sweet.

But isn't it rather risky for him to go over into Cuba? Some of those chocolate-colored young ladies in that "Pearl of the Antilles" will be making "goo-goo eyes" at him, and then we will Rambler be!

And just think, if a Cuban girl should be able to accomplish what no Californian belle has been able to do!

Rambler, you'd better come to Chicago.

The Thanksgiving Number of the Ladies' Home Journal is replete with good fiction and interesting and novel features. It opens appropriately with an article which tells "Where the President's Turkey Comes From." Then there are delightful stories by Heczkia Rutterworth and Laura Spencer Porter, and a new love story called "Christine," by Frederick M. Smith. Cleveland Moffett has an interesting story about lra D. Sanicky, the great evangelist, and Edith King Swain recounts the famous ascents she has made in various parts of the world. Will Bradley's original designs for a house begin with the breakfast-room, and Wilson Eyre, Jr., presents plans for a country-house and a garden. Mr. Bok gives much good advice to young married couples in his editorial. Another most timely feature is, "Why Should a Young Man Support the Church?" by the Rev. Francis E. Clarke. Many home-made Christmas gifts are shown, and the first of "The Journal's Amusing Tales" appears. The regular departments are exceptionally good, and the illustrations superb. By The Curtis Publishing Company, Philadelphia. One dollar a year; ten cents a copy.

Note.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one of these buttons as it will enable people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more bee plants, and at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."
The Chicago Convention.—One of our correspondents, who evidently is interested in the next session of the Chicago Bee-keepers' Association, writes as follows:

"Mr. Editor:—In the notice of the convention to be held in Chicago, Dec. 5, it is said that the railroad rate is $1 for one fare plus $2.00 for the round trip. That is given as the reason for holding the convention at that time. But if this is a convention of Chicago bee-keepers, a rate of that kind would not be any benefit to them, nor indeed to any one living within less than 70 miles of the city. Is it to be understood that Chicago includes all the surrounding States?"

PLAIN BEE-KEEPER.

No, Chicago has not expanded to quite that extent. But there's nothing small! Chicago bee-keepers, and residence in Chicago is not essentially requisite to membership in their society. Indeed, at their previous meetings, bee-keepers from a considerable distance have generally taken a prominent part. The live-stock show will bring to Chicago quite a number who are more or less interested in bees, and the low railroad rates will, it is hoped, attract others. There is no reason why there should not be the same gathering of bee-keepers in Chicago Dec. 5 as were formerly gathered at the meetings of the Northwestern Association, so pleasantly remembered by many as among the most successful bee-conventions ever held.

Fastening Frames for Hauling may be accomplished by driving a nail partly in at each end of each top-bar, or by slipping wedges between the top-bars at each end. R. F. Hobermann gives, in Gleanings in Bee-Culture, a plan that may be better, as follows:

A separator cut into four pieces will do. Lay this across the ends of the frames and drive a small tack through this into the bar, and they will not only keep from moving sidewise, but the piece across will prevent the frame from swinging at the bottom.

Glucose-Feeding.—A remark in "The Afterthought" calls forth the following:

Mr. Editor:—On page 61, Mr. E. E. Hasty, referring to an editorial on page 57, says: "It is somewhat in the line of news to be told that one can feed a ton of glucose to his bees." Do that mean that it is news that bees will take so large an amount, or that they will take glucose at all? No. It is hardly news that bees will take glucose at all—sometimes. They are not likely to feed upon it voraciously when good, honest nectar is within easy reach. Whether under any circumstances a very large amount could be fed at one time may be questioned. The editorial does not distinctly say what our sharp-eyed "afterthinker" seems to understand it to say, namely: "that one can feed a ton of glucose to his bees." It says that a certain bee-keeper tried to feed that amount. That does not say whether the whole of that amount was taken by the bees. Even if that amount was all taken, it would not necessarily be such a very large amount for each colony, when it is noted that the colonies were numbered "by the hundreds."

Glucose as bee-food is reported in Le Progrès Apicole as producing diarrhoea in some cases and constipation in other cases. Some across the Atlantic report no inconvenience to the bees from its use, while others report heavy losses by death where glucose has been fed. These discrepancies are accounted for by the inconstancy of the product, some samples being pure, or nearly so, while many others contain free sulphuric and hydrochloric acids, etc., and often traces of arsenic.

The safest thing for bee-keepers to do with glucose is to let it entirely alone. "Trench not, taste not, handle not," is good advice.

Price of Honey receives further attention in Gleanings in Bee-Culture, without however materially altering light. At least there seems no reason to change the view heretofore given in these columns, and it may be well to repeat that one will not be likely to go far astray if one closes promptly with any offers made at last year's prices. A note from Dr. Miller has some bearing on the subject. He says:

"I'm sorry to say I had not time enough to call on you either on my way to Jacksonville or on my return. I did, however, make a pop-call on R. A. Burnett in passing. He promptly introduced the subject of prices on honey. I had considered his theory that rumors of a big crop helped to increase sales without lowering prices, and thought it utterly untenable. I do not know that I have entirely changed my views, but I must confess that after hearing his five cases right out of his experience that seemed to support his theory, I don't feel so sure of my ground as I did. It seems, however, that in the long run the greatest good to the greatest number ought to be secured by having 'the truth, the whole truth, and nothing but the truth.'"

"The Life of the Bee!" by Maurice Maeterlinck, translated by Alfred Sutro, is a unique work. It is not intended to supplant or to supplement any of the text-books as a text-book. The author says: "It is not my intention to write a treatise on apiculture or on practical bee-keeping." The man who has mastered the contents of one of our excellent text-books will learn nothing new from this work. But he will find the everyday facts about bees, with which he is already familiar, painted in such exquisite fashion that they will seem almost new to him.

The book contains 427 pages, with an undue amount of white paper, for the page measures 7½ by 5 inches, while the printed portion is only 4½ by 3¼.

One wonders at such spelling as "labour," "favour," "savour," and "waggon" in a book fresh from the press, and still more to find "swarm" used for "colony," and "hive" with the same meaning. But these are minor matters, and we must remember that the book is a translation.

The author says: "I shall state nothing, therefore, that I have not verified myself, or that is not so fully accepted in the text-books as to render further verification superfluous. My facts shall be as accurate as though they appeared in a practical manual or scientific monograph." Yet the practical bee-keeper will hardly forbear some doubt as to the accuracy of some of the supposed facts. Dezerion's hive, "still very imperfect, received masterly improvement at the hands of Langstroth;" when, as a matter of fact, Langstroth completed his invention before ever hearing of Dezerion's hive, and no after-improvement was made. (Page 15.)

Our author will delight the heart of the Rev. W. F. Clarke, when he teaches that the bees "ensure the preservation of the honey by letting a drop of frame settle in from the end of the sting." (Page 43.)

Sixty or seventy thousand as the number of bees in an average swarm will stretch the credulity of the average bee-keeper, to say nothing of our good friend, the editor of Gleanings in Bee-Culture. (Page 46.)

In speaking of preparation for swarming, the author says: "The bee-keeper has only to destroy in their cells the young queens that still are inert, and, at the same time, if nymphs and larve abound, to enlarge the store-houses and dormitories of the nation, for this unprofitable tumult instantaneously to subside, for work to be at once resumed, and the flowers revisited; while the old queen, who now is essential again, with no successor to hope for, or perhaps to fear, will renounce this year her desire for the light of the sun."

Beautiful as is the language in that sentence, and much as the practical bee-keeper would like to believe it, he will hardly believe it a general rule that when preparations for swarming are made, all he has to do is to destroy queen-cells and give more room to secure the abandonment of all further thought of swarming for the season.

Do swarming bees carry with them a certain amount of pollen?" as stated on page
The Buffalo Convention.

(Continued from page 394.)

Response by Dr. C. C. Miller.

Just a little while ago Pres. Root said to me that he wanted me to say a few words in response to Dr. Smith's address of welcome, and my heart sank. I said that I didn't know that I could put on dignity enough for that; but when I found that I was to respond to plain, unadulterated Smith, I made the task easy for me. So I say that there has come to me something of a surprise. If there is one thing above others that I don't want to see the time taken up with in a convention of beekeepers it is an address of welcome and the response thereto; and in trying to make a response the thought generally will be, now what shall I say that is different from what has already been said? In what has been said today there has been an intellectual word of welcome, recognizing with a great deal of intelligence and probability what we are trying to do for the world, so that I do really feel that we are welcome. We are welcome to this room, which is something that we are really receiving something of real value, and the words that have been spoken of encouragement as to our work has been something that is of value, and I do hope that fruits may stand upon the shall be.

Now, if you please, allow me to turn the tables just for a moment and speak a word of welcome—let me make an address of welcome. For we have heard such words from such men; we do welcome a feeling of recognition, of intelligent appreciation, and I want to say, as a citizen of the United States, a word that I have said in private, that we welcome our brethren from across the line. I don't know whether the Canadian brethren know how kindly we feel toward them. I trust that the feeling of brotherly affection that these words of welcome that our plain friend Smith has spoken to us will make us feel this stronger than we ever have felt it before; and that in the moving of a kind Providence the good work that may be done will be a pleasant thing for us to remember all the remaining days of our lives.

The convention was then favored with a song by Miss Ethel Acklin, of Minnesota, entitled, "My First Music Lesson."

Mr. N. D. West, one of the inspectors of black brood and foul brood, of the State of New York, then read a paper on the subject as follows:

Black Brood, Foul Brood, and Bee Inspection in New York.

The bee-keepers in several counties of eastern New York have had a hard fight with a new contagious bee-dis-

ease. Dr. Howard, of Fort Worth, Tex., has made many examinations of diseased brood sent to him by myself and others. West has said, the disease being new and differing from the old time foul brood, he would, for convenience, call it "Black Brood." It is very similar to foul brood, which we have known for years, and the treatment for its cure is about the same, but it does not yield so kindly to treatment, and it spreads more rapidly.

With us the black brood started at Sloansville, in the northern part of Schoharie County, some six or seven years ago. Many whole apiaries died, and the disease kept spreading on and on until it had reached other counties, and it seemed as if all bees must die. The disease spread rapidly, and some of the surrounding apiaries for many miles. It was known as "foul brood," and surely it was a foul brood.

Finally, Charles A. Wetling, Commissioner of Agriculture of the State of New York, appointed Mr. Frank Boomhower as his agent for bee-inspection, to exterminate the disease in Schoharie County.

Mr. Boomhower went to work and inspected apiaries, and he caused a great many colonies to be burned, hives, honey, bee-stands, etc., wherever was needed. The bee-keepers did not object. Many apiarists who knew they had diseased bees would not object. It was considered the bee-inspector an enemy who delighted in destroying their bees because the law gave him the opportunity to do so.

Quite late in the fall, Mr. Boomhower laid off from his work as bee-inspector. In 1899 the bee-law was passed so that it was the apiarist's chance to cure his own bees, and if he was successful the bees will not be destroyed. Commissioner Wetling has since appointed four agents as bee-inspectors for the State of New York. These agents are inspecting apiaries and are instructing the beekeepers as best they can how to treat their apiaries. They have discovered that the diseased colonies are weak. If their owners will treat them properly, and do all they can to prevent the further spread of the disease according to instructions given by the agent, the diseased colonies are not destroyed.

This diseased territory, having Sloansville for its center, is about 60 miles east and west, and about 45 miles north and south. Many apiarists have

Green were the leaves at sunset:
To-day they're scarlet red;
Like men they play their proper part.
Then fall to earth bed.

Gleanings in Bee-Culture.
so learned to treat and handle their diseased colonies that our apiaries are improving. The prospects are better. Bee-keepers in the midst of the disease, who once thought the trade would sink, are now beginning to believe that, with good management, much can be accomplished. The black bees do not get diseased as quickly as do the honey bees, and they stand it better when they do get diseased. Disease is much more common among Italian bees, when very strong, and having a good, young queen, and the honey bees are more susceptible to the disease than the black bees. The black bees have not the disease as much as the honey bees. The number of colonies of Italian bees, and their condition, is much better than that of the honey bees.

But the season has much to do with the progress and curing of the disease. I find that bee-keepers have been much more interested in treating diseased black bees and effecting a cure this year than ever before, on the territory where I have been working. Bee-keepers should not allow any colony, no matter how weak and die or get robbed on their surface. All colonies should be kept strong during the summer, and in the spring and fall seasons the apiaries should be prepared for disease. Good queen, and all weak colonies removed from the apiary where disease exists.

Colonies treated for black brood, by some method, is all right. Every method should have plenty of honey bees, and there should be plenty of honey in the field, or the bees should be fed with a syrup or good honey cake. One reason that disease sometimes occurs is the failure of them to moisten the honey. A comparison of reports of the agencies for the work begun on the first of May to the 21st of July, 1900,

- Number of colonies visited
- Number of colonies examined
- Number of colonies destroyed

The Commission will be pleased to receive letters from those in this State who have bees, and it is anxious to do anything in its power to increase the products of apiculture.

The names and addresses of the four New York State Inspectors of Apiculture are as follows:

- M. Stevens, Pennsville, N. Y., for Oswego County.
- Charles Stewart, Sammounds, N. Y., for Fulton County.
- F. Wright, Aphon, N. Y. or Albany County.
- N. D. West, Middleburg, N. Y., for Schoharie County.

Pres. Root—This matter of black brood is before you. Perhaps before we go on to the general discussion we should hear from Mr. Stewart, one of the inspectors.

Charles Stewart, of New York—I don’t know as I have anything to add to what Mr. West has said except that we find throughout the locality where black brood is at its worst that it is a case of the survival of the fittest. As he said, the yellow race of bees is in much better condition than the blacks or the Carniolans. Then, too, it is a survival of the fittest among bee-keepers. Those who were negligent or careless have lost nearly all their bees, especially those who have black bees. Those who have been thorough in their work have been successful. I think the other inspectors will agree with me that the disease has not spread as it has formerly, owing to our work about April 1st, and our going about and cutting off all colonies that were weak, seeing that they were destroyed and put out of the way, and no robbing took place in spring time. It seems that black brood has spread in my section but very little during the past season, and all who are practical bee-men are greatly encouraged and feel that they now have the disease under control so much so that many talk of buying bees again and going back into the business.

Pres. Root—It is very gratifying to know that the disease has now been got under control, and I believe is now under control. A question I would like to ask is: Do you have any difficulty in distinguishing black brood from foul brood, or is there a difference, and, if so, what is the difference between the two diseases?

Mr. Stewart—There is a difference. You will notice, particularly in the stage in which the brood dies. In the late autumn, foul brood—a large percentage of it—died after it was capped and was usually very stringy. I am speaking now of foul brood. Black brood looks much the same as the disease before it is capped, the greater part of it, not much dying after it is capped. Occasionally you will find a combination of both. Sometimes you will find a combination of black brood and foul brood, and again, a combination of black brood and sickled brood, and we have sometimes a confusion of diseases, but the main difference between black brood and foul brood is the time at which the larva dies, and its ropiness; also that the black brood is much more contagious than the old-time foul brood.

We have some apiaries in various places where they have had foul brood for five or six years, and, perhaps, it has not spread to adjoining apiaries; whereas, if it had been black brood, you are sure to have spread over a whole county, showing that the black brood is much more contagious than the foul brood.

Pres. Root—Is it necessary to disinfect the hives in the case of black brood?

Mr. Stewart—We always advocate that, using corrosive sublimates or naphthaline, or something of that character. It is if it is simply shaking them once on the same hive, and they are healthy up to date; but this, perhaps, is not a working method among bee-keepers, because some of them are a little careless and they would not be successful, and we would be censured for it, so we advocate shaking twice and also disinfecting the hives. We think it is safer to be over-cautious than not to be careful enough.

Edwin B. Tyrrell, of Michigan—Does the black brood spread in the same manner as the foul brood?

Mr. Stewart—It is spread by the honey being robbed from one colony by another, but sometimes it is spread we hardly know how. I have had an instance called to my attention in a locality where the bees were all healthy, you might say, and found only once or twice one hive injured, and afterwards one man that had a large apiary found combs of honey near him that somebody had thrown out for the purpose of infecting his bees; but he had no enemy, or someone you have never injured in any way, yet he feels that he has lost his own bees and is a little envious of you because you are in a flourishing condition, and occasionally, it spreads in that way. It is something I dislike to mention, but it has been brought out, and such a case will occur occasionally. It is spreading in other ways, because it will spread quite a distance, two or three miles, when you can discover no robbing. Perhaps it is by a bee flying from one colony to another, or there may be carried by the bees to the flowers and other bees get those germs from the pollen. We know we are able to tell you, but we don’t know now, that is something no one can tell.

A Member—I would like to know something about the treatment of these diseases.

Mr. Stewart—We have had very successful treatments. We have been shaking them on to comb foundation, and in about four days taking those combs away and shaking the bees on to another set of foundations, and by destroying the hive, or using another hive. The bees from that time on will be healthy unless they reach some infected honey.
F. J. Miller—Do I understand that it is simply the McEvoy treatment for foundation that Mr. Stewart object to? Mr. Stewart—With the difference that we recommend being on the safe side by disinfecting the hive by boiling or some other means of burning. Mr. Case—How can you manage to get the bees from the combs or the starters on which you first shake them, on to the foundation that you are going to use? Mr. Stewart—You could simply put them in a box in a cellar until they have thoroughly used up the honey in their honey-sacs, and then put them on comb feeders, as I said the other day, and add the honey along with the bees. The difference is small, but if you are using a lot of bees, it is very important.

N. N. Belzinger, of New York.—I have found it better to use the McEvoy combs, or put them in a box in a cellar for 48 hours, or something like that.

Mr. McEvoy—I agree with Mr. West on that point, when he puts them in the cellar he feeds them.

THE USE OF COMB FOUNDATION.

"Is the use of foundation profitable in the production of comb and extracted honey?"

J. Greiner, of New York—I would say that the best, and most profitable, use of comb foundation, in the production of comb honey as well as extracted honey, and the question in my mind is, do we want to use comb honey with comb foundation as we could without? That is the only point why I hesitate sometimes in advocating and using comb foundation in sections, it is the very best comb foundation that could be procured; and yet I will say that I do not use the flat-bottom foundation—there might be excellent reasons of that. I have used the regular comb foundation as it is manufactured by other manufacturers. I can detect the comb foundation in almost all my comb honey, and my wife very seriously objects to my using comb honey or bringing such in the house for use, on account of this comb foundation. I think we really should say it was profitable to use. Of course, in the production of extracted honey, if you don't have the combs there is no other way. If you have to shake the bees off the way to do is to use comb foundation.

Dr. Mason—Wouldn't the bees build it if they didn't have any? Mr. Greiner—They would, but it would not be as profitable, and we want as tough combs as possible. In the brood-chamber certainly it is profitable in more than one way to use comb foundation. You get splendid combs, and a good deal quicker, and the drones are easier to get out of the cells, but there is no other way that we can prohibit the rearing of drones than by this method.

Dr. Miller—I don't doubt at all the importance of the question. I do doubt the advisability of taking much time in discussing the reasons for the differences of opinion. It occurs to me that if Mr. Hutchinson were here, he might answer these divergent questions asked and simply get opinions how many think so and so, and it occurs to me that if Dr. Hutchinson were here, he might answer these different questions that are required, and ask us where we will put ourselves on record, I believe it would be of use. Simply get the number of those who think they want to use foundation, and so on.

Mr. Hutchinson—Is it profitable to work for extracted honey, to hive swarms upon full sheets of foundation in the brood-nest? How many would favor hiving swarms on comb foundation in the brood-nest when working for extracted honey? Evidently, most of us use full sheets. How many would use comb foundation? How many would use starters? Is there any one here who would use starters in the supers only? Mr. McEvoy—I would make a half sheet of it by using it saw-tooth fashion.

Mr. Hutchinson—How many would fill their sections full of foundation? You see most of us use full sheets of foundation. Is there any one here that would allow the bees to build their supers combs in producing extracted honey?

Mr. Wilcox—The foundation costs me nearly a dollar a hive, and by using a few sheets of foundation starters they will build a few short combs; it is more economical in the brood-chamber. I use old combs in the supers.

Mr. Betsinger—I voted for using full sheets of foundation in the sections. Now, I don't know anything more about that than you before did. The question is why I use them.

Dr. West—We haven't got the time to tell why. We have got to take the expression in this way.

Mr. Hutchinson—I will fill them full in my locality, because they can finish the combs so much quicker and take care of the harvest. I think if the honey-flow was slow it might be more profitable to allow them to build combs in the sections, but when it comes in with a rush, and they can fill the super in three days, the time to build the combs and gather the honey, and for that reason it is profitable to use foundation, because they can get storage room quicker; but I have found it to be a mistake. I want to say that the use of foundation in the brood-nest when hiving swarms and working for comb honey, in my locality, I have taken this opinion off a year ago and put them on the new, and have the same bees working in the sections again in 20 minutes, with all the enthusiasm of a comb of honey, and all the combs that go in must go in those sections, and they will build brood-combs, and as fast as they build the queen will fill them with eggs, and I have gotten as nice honey as by allowing them to build their own surplus combs. But, as far as results are concerned in surplus honey, I can get more by allowing them to build the new ones on the brood-nest. I would confine a swarm to about five combs.

Mr. Abbott—As we seem to be establishing a practice here, I cannot see anything to gain by it, cannot see any advantage to be gained by it. I do not think I can see anything in it—a lot of people holding up their hands that they would do this and that. A National ‘bee-keepers’ meeting is such a thing, where a certain amount of information and instruction and information at the same time, and to hear from these people who are not in the habit of talking, I want to hear Dr. Miller and we want to be able to satisfy.

Difficulties in Breeding for Long-Tongued Bees.

By C. P. Daidant.

There has been considerable discussion of this subject for some time past in all, or nearly all, the bee-papers. There was a time when a heated debate, and would throw myself head first into the battle on the side which I thought right. But that time has gone, and, although I still love to have my say, I much prefer to say it when the two sides are through and the matter seems very nearly settled one way or the other. Yet it is much pleasanter to discuss bee-culture now-days than it was in years gone by, when each man thought those who did not agree with him on any particular question on the natural history of the bee must have a special spike against him. Hot words and epithets in scientific discussions are becoming a thing of the past.

The question of long-tongued bees is not new. When the Italian bees were first imported into America, many apiaries, it was held by many that they could gather honey from the red clover, while the black bees could not. I remember an old neighbor who had bought Italian bees of us, when I was hardly yet a man, and came one day in great glee to tell us that his Italian bees were working on the second crop of red clover. "And," said he, "the black bees see them at work on it and try it, too, but they can't get anything out of it. Their tongue is not long enough." I went with him to see this wonderful performance, but it seemed to me as if both the Italians and the black bees were industriously at work and shared alike, for, although some bees seemed to fly about over the field without any result, others would stop long enough on a blossom to show that they harvested something. And this seemed to be quite uniformly the case with either race. And our old friend could hardly be relied upon for something very positive, as he was in the habit of ready believing what he earnestly desired. But, later on, I have seen, without doubt, many Italians at work in a field of red clover, while the black bees were totally absent. In that case there was either a difference in length of tongue or a difference in tastes and abilities. Yet the actual results in pounds of harvest could hardly be proven to the advantage of the red clover, for, even without pollination, we have always seen a better result with the Italian bees than with the black. But it can not be doubted that there is a perceptible tendency to longer tongues in the Italian race.

The discussion of the long-tongued bees will have the result of causing investigations in that direction, and breeding as much as possible from the bees showing the greatest disposition to harvest honey from flowers with long corollas, or from the breeds of bees producing the largest results. After all, is not this what we are seeking?

But, can we expect to get a set type, an invariable breed of long-tongued bees, readily? Can we make sure of a distinct race, in a word, upon which we may positively rely to harvest honey from red clover whenever the honey is in it? I think not. It seems to me that, handicapped as we are by the almost impossibility of controlling the selection of the male in the fertilization of queens, we cannot for a long time expect to duplicate our best breeders and produce an invariable race. But, aside from the difficulty due to this obstacle, we have before us the tendency of all beings to return to the original type.

Those who have persistently worked for years—for a lifetime—to the change desired in breeds of horses, pigs, cows, chickens, and in fact in the improvement of any domestic animals, or plants, or trees, those men know how little can be accomplished in a single man's life. If you take a breed which has already well-marked traits in the direction you seek to follow, you can only hope to make a very slight improvement by years and years of persistent effort. Have any of my readers ever tried to produce a new kind of potatoes, or a new grape, by artificial fertilization? If they have they will remember how many worthless specimens they have brought forward, and how few good ones. Many of us have made such trials in the hope of producing something far ahead of our neighbor's stock, but how many disappointments?

So it must be with the bees, and worse, since we cannot control the reproduction as we control that of most of our domesticated animals.

But, nevertheless, it would be an error to discourage those who try, for they are certainly on the right road. It is not only by repeated trials and by selection, long-continued, constantly discarding the inferior subjects, but constantly keep-

An Experience with Black Brood in New York.

BY P. W. STAHLMAN.

SOME time ago I promised to report my experiments on black brood, the following being the first season of my work with this disease in the Netherlands. In the fall of 1899 I moved two colonies of black bees (apparently clean and free from any disease) from an infected apiary. Both were very populous, and when the honey was removed and the examination made, the sealed brood in three combs was found in No. 1, and a few cells were rotten; No. 2 was found to contain some sealed brood also, but free from disease. The first examination was made on the 20th of Nov., and our presence was known to the bees, as the bees were kept in the cellar for about six days and fed with bottled honey. While this was going on, I cut from the combs of the same hive five pieces of combs, six inches square, on an average, containing neither honey nor pollen, and fastened these pieces of comb in a new hive, contracted to about five frames, and then turned the bees onto these combs, only to find about two weeks later another case of disease again in its first stage.

I now took what few bees were left (perhaps two quarts or more) and put them on starters of comb foundation, and contracted to three frames, leaving them in the same hive, just as it was, and using the same combs, and all was well. I think I was more successful in the first experiment, as the disease never appeared again. This was taking bees from their winter quarters to treat them at once. Today (Aug. 19) the swarm is a "dandy," and I have installed a famous Italian queen to produce the next year. No. 2 bred up to contain nearly six frames of brood, but when I put the last outside comb, full of honey, in the center of the hive, the whole thing was struck with the disease, and, of course, to be destroyed. The bees were shaken off the combs in front of their hive, on a large newspaper, and as soon as they crawled into the empty hive the newspaper was burned. In all cases the shaking was done at nightfall. The colony was left to work at liberty for four days, and then, without smoke, the hive containing bees (which contained no frames) and what comb they had built, was quietly set on the ground and a clean hive containing starters, a la McEvoy, was placed on the old stand, and then the bees were suddenly jarrt out of the box and were left to enter the prepared hive and go ahead.

All was well for about seven weeks, when, from some cause or other, the disease again began to appear. After a few days the colony, which was strong, was again treated in the same way, and today, after seven or eight weeks, it is clean and good. The combs were cut out and destroyed, brood, honey and all, and two tea-kettles of boiling water was poured over the frames and hive, giving it a thorough scalding, and, of course, the disease is gone. No. 3 being also a treated colony, our friend and I (whom I had treated in the same manner) cast a swarm. This swarm was hived on these scalded frames, with starters, the same cover and bottom-board and all the usual paraphernalia. The result was a healthy and populous, open for inspection to anyone, as the season was especially good for experiments.

It has been a wet season, and not of the best for honey. My colonies, four in number, are now headed as follows: No. 1, a queen from Kentucky; No. 2, one of a California stock; No. 3, a daughter from the Kentucky queen, and No. 4, a Carnolian. By this I mean to keep them free from disease next year, and increase my colonies. It takes Italian bees to fight black brood. Black ones are "no good."

Hance Co., N. Y.

Questions and Answers.

WINTERING BEES ON THE SUMMER STANDS.

I wish to ask about wintering bees on the summer stands. I have the "Langstroth on the Honey- Bee," but I can't find much about wintering bees on the summer stands in it. I am going to winter two colonies on the summer stands; they are eight feet apart and have plenty of stores; they are in eightframes. Have wintered hives in the cellar and two winters. How must I pack them and when? The winter here is usually cold, sometimes 30° below zero. Last year I put the bees into the cellar Nov. 26, and took them out Apr. 2. The hives face south. What shall I pack with?

MINNESOTA.

Answer—You must have overlooked what is said in Langstroth, beginning at page 326, and especially pages 336 to 344. If you have always been successful in cellar-wintering, it is doubtful that you can do better outdoors. The packing should be done early enough so that you will not suffer from any very severe freezing. Langstroth recommends for packing material, chaff, straw, forest leaves, woven rags, and corks. The last is probably the best, but it is not always easy to be obtained. Even corkslings are quite popular, and are not generally difficult to get.

Introducing Queens.

A queen I ordered some weeks ago arrived in good condition. I introduced her according to directions, the colony being queenless one day. After 24 hours the bees had done nothing to the cage, the weather being rather cold; so I pulled off the card at the end. The following day, it being still colder, the queen was still in the cage, and almost frozen. I then took her out and dropped her among the bees. A few days ago I examined the hive but found no queen, eggs, nor unscaled brood. Was I at fault in my way of introducing, or how do you account for the disappearance of the queen?

OREGON.

Answer—Were you entirely certain about the disappearance of the queen? Many a time has an experienced beekeeper looked in vain a long time without finding a queen, especially a queen that is not actively engaged in laying. Of course, you may now be sure, some weeks later, for if present she would be laying. Dropping an almost frozen queen among the bees was hardly the wisest thing. From what you say it would appear that the queen was more or less separate from the bees, otherwise she would not have been chilled. The result probably would have been different if you had put the cage right in the cluster of bees so that there would be no question as to warmth, and then at their leisure the bees would have liberated the queen.

Baked Sweet Potatoes for Bees—Finding Black Queens.

1. Are baked sweet potatoes good bee-food? They are almost entirely sugar and starch, and the bees eat great holes in them.

2. Is there any way of finding the queen in a colony of black bees besides shaking them all off the combs in front of the hive in the evening like clover? We have hunted mine over a hundred times and never could find one.

3. Why are queens dearer in the spring than in the fall?

LOUISIANA.

Answers—1. I don't know. C. should suppose they might answer a very good purpose if consumed while bees are not actively flying, but they might be had for winter stores.
2. The usual way is to look over the combs till the queen is found, and I suppose that is the way you mean you have done a hundred times over. After you have looked over the combs two or three times without finding the queen, it is hardly worth while to continue. Close up till some future time, not sooner than half an hour, and you may then find her the first thing. Another way is to put the combs in pairs. Put two of them into an empty hive, the two close together but an inch from the wall of the hive. Put another pair at the other side of the hive. Displace the rest in the same way, sending a couple of empty combs, only leaving one pair in the hive on the stand. Now look at the first pair, lifting out the frame nearest you. If the queen is on either of these combs, you may be sure she is on the side next the other comb, so to say out of the way of views. As you lift out the comb glance over the side of the comb left in the hive, and if you do not see the queen on that comb look quickly at the comb in your hands on the side from you. If unsuccessful in your search through the different pairs, let them stand for a time, and you will find the bees showing signs of uneasiness when the queen is missed. The pair that has the queen will remain quiet, and your search will now be brought down to those two combs.

3. Like other commodities, the law of supply and demand affects the price of queens. Queens are plentiful in the fall; it is easy to have them in nucleus, and it is not easy to winter them except in full colonies.

**Queens Killed in Introducing—Saving Queenless Colonies.**

1. About Sept. 5 I ordered half a dozen queens, but did not get them until the 28th. The breeder sent no directions for introducing, so I followed as closely as possible the directions in the little booklet put in with the package, one being killed when received; 48 hours after I put them in I looked in and found a lot of queen-cells which caused me to feel uneasy, and I examined the front of the hives and found two dead queens. I think all the others were killed, as there were cells in each hive. Why was it they were all killed?

The bees had a good lot of honey and were getting honey from asters.

2. What can I do at this season of the year to save the queenless bees?

**Answers—**

1. It is impossible to tell what may have caused the loss without more particulars, and it is not certain that full particulars would allow an answer to be given.

2. You can buy queens to introduce to the queenless colonies, and as they will have been queenless a considerable time they ought to accept queens readily. If, however, they have reared young queens already, they will make trouble. It is possible you have colonies with laying queens that are weak in bees, and it would be a profitable thing to strengthen them with these new bees.

The "Old Reliable," seen through New and Unreliable Glasses.

By E. E. Hasty, Sta. B Rural, Toledo, O.

MONUMENT FOR THE BEEFLY-ESCAPE IDEA.

But Mr. Alpang's adaptation of the bee-escape to keeping a room clear of flies—that seems to have gotten beyond theory to practical success. Who knows but some one sometime will vote him a monument for that? And he needn't use the monument for a good long spell yet, either.

MELTSE, HONEY, TURP, ETC.

Yes, and do you see that not only Dr. Strickland, of Tennessee, but also the Battle Creek Sanitarium, of Michigan, are pushing methods as a substitute for honey? Well, "Every tub on its own bottom;" but the venders of the good old tub need hardly be expected to lead in singing hallelujahs to the poor new tub. Page 611.

CONDUCTIVITY OF HONEY.

Honey is queer about its conductivity. Perchance it is partly because of the speed with which both the absorption and exhalation of water from it goes on. If we try to cool warm honey, recently cooled air (practically sure to be damp) at once envelops the surface. Surface soaks the vapor, and in changing it from gaseous to liquid condition sets free the latent heat—practically manufactures heat. If we try to heat cold honey we are liable to find that a thin film at the surface has got very thin in the other sense of the term. This liquid water is easily changed into vapor (at the surface) and so practically manufactures cold at a rapid rate. The amount of heat which an ounce of water vapor will change to the latent state, and so disappear or cool, is thus almost beyond all possible calculation, the how and the why of it that is takes such an amazing spell to get cold combs fit to extract. Hang them far apart—up to the top of the room—and give them two days if you possibly can spare. Another good way is to extract what you can while in a half-warm condition, warm them some more, and then extract again.

WATER AS A CONDUCTOR OF HEAT.

"Water, if kept from circulating, is as bad a conductor of heat as copper." That's a big sentence. Better we keep it on probation awhile before we swallow it whole. An ounce of water distributed in the caff of a cushion is pretty effectively kept from circulating. Would it, or would it not, affect the cushion like mixing in an ounce of elder-dow? I'll choose the down for my bees. But when it comes to honey, I'll admit without argument that honey is a poor conductor—and the lack of mobility in its particles helps it to be so, very likely. Page 613.

POSITION OF BEES IN WINTERING.

"Observer" does well to call our attention to the fact that wintering each individual bee in a four-inch cluster must furnish heat twice as fast as a bee in an eight-inch cluster. Also we have thought that spacing the combs is a help towards the further part of the argument, feel about ready to tumble to his argument that it is not a help, but a disadvantage. But the bees of massed in a "Hill's device," with their backs up against a warm, dry cushion, and getting honey from below. "Observer" does not handle that case, I should say. Page 613.

BULK COMB HONEY vs. SECTION HONEY.

Mr. O. P. Hyde, bees do not create honey out of nothing. If your bees store twice as much bulk comb honey as of section honey it must follow that somehow or other, actual or potential, there is a waste of one-half by the section-storing bees. That's not the way bees do at my yard. Yet I'm not sure but some strains of bees will do just that when you try to get them to work in sections. Page 616.

CRABBEDNESS AND DYSPEPSIA.

"Zatsa," Prof. Cook? Does crabbedness breed dyspepsia? The popular impression is that dyspepsia breeds crabbedness. Perhaps the bottom fact is that they mutually foster each other. Page 618.

SCREEN HIVE-TOP AS A ROBBER BOTHERER.

Take off the cover of the hive, and fasten on the screen top as if for moving. We had several excellent devices to bother robbers before, and this evidently adds another. I have plan to have our quiver full of them—and wit enough to select quickly the right one to shoot in sudden need. Page 621.

THE QUEEN AND LAYING OF DRONE-EGGS.

The sharpness of the queen's desire to have some drone-comb to lay in is alluded to by Mr. Atchley, on page 630. Probably many of us have noticed this. He thinks the queen finds it easier to lay drone-eggs. How about the probability of laying drones? If you are at all proficient you may have at least a near approximation. May be supposed that a sort of nerve exhaustion has been run up by the long laying of myriads of unfecundated eggs, and that the laying of unfecundated eggs does not make so large a demand on nerve force, nor exactly the same kind of a demand. She is taking a rest not by quiescence, but by change of action. Even ye sapient editor may write, and write, and write, until it is a rest to saw dry hickory wood. Howsoever, it is also not unimaginable that the Queens lay laying eggs industrially because there are no more spermatic particles ripe enough to use.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of $1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it.

The Home Circle

Conducted by Prof. A. J. Cook, Claremont, Calif.

KINDLY INFLUENCE OF FLOWERS AND BEES.

I want to thank Prof. A. J. Cook for the "Home Circle" in general, and in particular for what he said about flowers, on page 624. The ladies-wife and daughter—of this ranch are great lovers of flowers, and have about 10 plants of different varieties in the house; but I never thought of seeing any particular moral effect on the behavior of our farm dog—a thoroughbred shepherd (15 years old now), that has always been very strict about keeping his flock on the roads and barking at any stray dog or cat. I think this is a very nice way of seeing to it that we all keep our property in good order, and do not have strays on the premises; but it is a fact that he never barks at people when they turn into our yard; on the contrary, he always goes out to meet them, wagging his tail, to strangers as well as friends, as much as to say, "That is right; come right in; you will find a welcome." He even allowed a thief to carry off a sapper of honey from my apiary one night a few years ago. I don't want that trait of his to be known very widely.

Instead of giving flowers the credit of "begging a more kindly, genial spirit," I have been inclined to come at it from the opposite way, that people who are naturally kind-hearted and genial, exerting themselves to cultivate those traits are the ones who, most naturally, take to flowers. It doesn't matter which way you take it, the influence is good both ways.

But what about bee-keeping and the influence for good that the "busy bee" exerts over those who engage in this business? It may be a little on the order of "compulsory education," but it is certainly a great school in which to learn patience and self-control-elements very essential toward the possession of a genial, kindly spirit. Who ever knew a beekeeper and real lover of bees who lacked those traits? As a rule, I find them the most sociable people I meet; even though perfect strangers to each other, it does not take long to get acquainted when they are engaged in keeping bees. There seems to be that fraternal feeling existing between beekeepers that does not obtain with people of almost any other calling.

I got out my paper and pencil to make a report of my doings with the bees the past season, but my mind persisted in running off on that track, all on account of that article of Prof. Cook's, consequently my report will have to wait.

Mitchell Co., Iowa.
A. F. Foote.

INDIO, THE SUBMERGED.

There is a very curious thing about the soil of California. Dr. Hilgard—the distinguished student of our State University—puts it very graphically. He says that we have several farms under the other, he means that our soil is away down. If we should bring a four foot soil to the top it would be immediately productive; or, if we would expose a soil four or five feet down, by removing the top soil to that depth, it would at once grow—if watered and cared for—a full crop of grain. This is why California is so immensely rich in its soil. It is an arid region and the soils have not been leached of the valuable fertilizers.

I now show you how I illustrate this truth. When I came here I graded my lots. I cut down two feet or so at one place. I commenced removing the surface soil as I would have done in Michigan, moving it to one side, expecting to return it when I had the grade to my liking. A neighbor, seeing my work, queried as to my plan. I explained that I needed not take that trouble; that the subsoil and sub-subsoil, etc., were equally fertile with the top soil. I acted on his suggestion, and, though I planted a part of my lots on this subsoil, yet all my returns were most as an overseer station on the "Espee" railroad. A little more than a year ago it was discovered to be an artesian valley. Wells were bored at slight expense, and a great flow of the most beautiful water was the result—wells costing but $250 or $300 gave, in some instances, 40 inches of water. The water is said to be of the very best quality.

The climate at Indio is, in summer, exceedingly warm—118° F. in the shade being not exceptional. Yet it is so dry that people do not mind it, and those suffering with pulmonary troubles find here a paradise. The microbes of tuberculosis find this place too hot, "throw up the sponge," and their victims rejoice in new found health and vigor. Thus we see that Indio is a veritable green-house, a pant conservatory. Cantaloupes and water-melons grow here in a perfection that makes Rocky Ford, Colo., famous, Oh, but they are sweet and delicious! Melons just like the dry heat of Indio, and, if well watered, give a sugar content that makes them savoury beyond compare. They come into market in June and July and thus antedate all other regions, except it may be Florida, and when it comes to quality, Florida simply is not in it. Last year—Indio's first year—she sent 2,360 carloads of these luscious pulp to market, mostly to Chicago. The crop sold for upwards of $25,000, and the cultivators received over $10,000. Single acres produced, it is stated, over $250 worth of extensively productive cantaloupes.

Here, as elsewhere, the traffic took all she dared to. But with reasonable traffic rates, we see that Indio has a great prospect ahead. Even with the present exorbitant express charges, the desert orchards are the most promising of all the new regions, and the Lower Salton region and the excellent water makes this endeavor improbable for much of the section—then Indio, so late a desert waste, will in the future be prized as a valuable addition to our great land. In the past it lacked a two instigate in this yearling town. The people are bright, intelligent, and full of hope and enthusiasm, which latter we visitors caught in good measure.

I am glad to give this picture, as it makes us all in love with our grand country, more to marvel at its inexhaustible resources. If the veriest desert can blossom out with scores of carloads of cantaloupes, what may we expect when our
water systems are fully developed? Let us talk around the home tables, at the social meet, on the street corner, everywhere, in favor of more energetic action on the part of the government to conserve and develop our invaluable water-supply.

JOSEPH AND HIS BROTHERS.

Wasn't that Sunday-school lesson of yesterday a most interesting one? A divided home, a partial father, a proud boy, and envious brothers. No wonder all this gave birth to bitter cancer and hatred, and stayed not until murderous intent against a brother stole into those jealous hearts. Aren't we glad that we have so many homes where discord is not known? Isn't it good that Uncle Sam set his great, splendid foot on polygamy in our fair territories? Don't we all rejoice that the Christ spirit is so rife among us that partial fathers and mothers are rarely found? All the children in the most of our homes receive the best that is to be given by food, loving parents. Can we give too much thought, study, or even money, if it tends to cement the love of brothers and sisters for each other? No doubt, Jacob's misdeeds and trials developed a character that has enriched the world. We believe that even Joseph, as true and chaste as he was, was ennobled by his great trials. That trials and afflictions may have a most blessed ministry in the building up of a proud character, who can doubt?

MOCKING-BIRDS.

The mocking-bird is one of our delights. Closely related to thrush and cat-bird of the East, it out-sings either. Ours is the very same that charms the bird-lovers of the Carolinas. It sends out its sweetest carols morning, noon and night, and even at midnight it wakes to sing. Its heart is full as it watches its little fledglings. Five growing, promising little birdlings! No wonder the wondrous song makes musical the very sunshine, and gladdens all our hearts. I rejoice that my evergreens, down by the barn, are so vigorous. Soon they will harbor more of these lovely singers. A happy pair, in these October days, give us lovely music the entire day through.

Red Clover Queens For 1902 Free

Long-Tongue Variety—Warranted Purely Mated.

We have already arranged with the queen-breeder who furnished Long-Tongue Red Clover Queens for us during the past season, to fill our orders next season. Although fully 95 percent of the untasted queens he sent out were purely mated, next season all that he mails for us will be warranted purely mated.

We want every one of our present subscribers to have one or more of these money-maker Queens. We have received most excellent reports from the queens we supplied during the past season. And next year our queen-breeder says he expects to be able to send out even better Queens, if that is possible. He is one of the very oldest and best queen-breeders. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, of beautiful color, very gentle, scarcely requiring veil or smoke.

Orders for these fine, "long-reach" Warranted Queens will be filled in rotation—first come, first served"—beginning as early in June as possible. It is expected that orders can be filled quite promptly (even better than the past season), as a much larger number of queen-rearing nuclei will be run. (But never remove the old queen from the colony until you have received the new one, no matter from whom you order a queen).

All Queens will be guaranteed to arrive in good condition, and will be clipped, unless otherwise ordered.

A Warranted Queen for sending us Only 2 New Yearly Subscribers

In order that every one of our subscribers who wants one of these Warranted Queens next season can easily earn it, we will book your order for one queen for sending as the names and addresses of two new subscribers to the American Bee Journal and $2.00. Furthermore, we will begin to send the Bee Journal to the new subscribers just as soon as they are received here (with the $2.00), and continue to send it until the end of next year, 1902). So, forward the new subscriptions soon—the sooner sent in the more weekly copies they will receive.

This indeed is an opportunity to get a superior Queen, and at the same time help "swell the list of readers" of the old American Bee Journal.

We are now ready to book the Queen orders, and also to enroll the new subscriptions. Remember, the sooner you get in your order the earlier you will get your Queen next season, and the more copies of the Bee Journal will the new subscribers receive that you send in. We hope that every one of our present readers will decide to have at least one of these Queens.

Address your order to:

GREETING ITEMS

Fairly Good Season.

Bees did fairly well the past season, considering the droughts. White clover did not amount to anything, bringing in only 25 to 50 clover bales. Spring count, and increased to 60, and have taken off, up to date, 2,000 pounds of honey. 1,000 of which is comb, and have sold most of this from my honey-room, at 12, and 15 cents per pound. I kept further increase back by caging the queen in the parent colony. After 9 days I destroyed all cells, and then released the queen. Honey is what I am after, and not the bees. Marshall Co., W. Va., Oct. 21.

Purity In Queens.

I saw an answer to my article on page 520 as to the purity of drones. Mr. Hartly, on page 617, does not understand, and said I did not believe that a queen that would produce black and golden drones was pure, and he goes on to say that if they are pure, the mate, in many cases, is brilliant in color, while the female is plain looking. But support that take do not agree with Leghorn chickens that are pure, and we will then produce white chickens still. What I meant was that our bees will, in general, produce all golden or black or black drones, and not two kinds from the same mother. I meant that if our queens and bees are three, then our drones should be one color. I am not after three banded queens, but I wanted to know if it could be possible that they were pure.

R. C. ABERNATHY.

Farms Co., Tex., Oct. 16.

Honey Crop Not Extra.

The honey crop has not been very extra here. I got 41 tons from 38 colonies, spring count, only 500 pounds of this being comb honey. “The Home Circle” is very delightful reading. H. A. H. ALLEN,

Poorest Year in Seven.

This has been a very poor year for bees in this part of the country. Although reports have been good, I fear they have been made only to keep the price of honey down. I have 180 colonies, and had 12 swarms the past season. I have experienced on other occasions, and will not have half a crop this year. I am in one of the best localities in the country. I have not in the past seven years and this has been the poorest we have ever had. I have taken the American Bee Journal for one year, and like it very much.

W. M. WILSON.

Tulare Co., Calif., Sept. 10.

Where Bumble-Bees Winter—Poor Season.

On page 108, I notice a letter from Thomas Wallace in regard to bumble-bees in winter. I suppose the majority of people think they go South, but it is not so. During the spring I was grubbing stamps, when I found proof to the contrary. I found one nearly 1 inch below the surface of the ground. I caught it by the wings when it started to “sees,” like all bumble-bees, and in 15 minutes it flew away. I found them the same way the latter part of September. The first thing bumble-bees work on is the gooseberry, and I have seen them fly until that blossom is in bloom.

The hornets, also, winter between the bark of old, rotten trees, for I have found them there very late in the fall. They were weak, the same as the bumblebees. I think they must winter here, the same as grasshoppers, snakes, toads, frogs, etc., which are never seen in winter. Last winter I found a snake which was covered with white leaves, where I was chopping cord-wood. I cut it in two with

Standard Bred Queens.

A Foster Stylographic Pen....

This pen consists of a hard rubber holder, tapering to a round point, and writes as smooth as a quill pen. The point and needle of the pen are made of platinum, alloyed with palladium, and are of great durability which are not affected by the action of any kind of ink.

They hold sufficient ink to write 10,000 words, and do not leak or blot. As they make a line of uniform weight at all times they are unequaled for ruling purposes.

Pens are furnished in neat paper boxes. Each pen is accompanied with full directions, filler and cleaner.

AMERICAN BOOK PUBLISHING CO. on the MARKET.

19,000 Postmasters use this kind of a pen. The Editor of the American Bee Journal uses the “Foster.” You should have one also.

How to Get a “Foster” FREE.

Send two new subscribers to the American Bee Journal for one year, with $2.00; or send $1.00 for the pen and one subscription to the American Bee Journal for one year; or, for $1.00 we will mail the pen alone.

Catching the Bee-Moth.
I saw in the Bee Journal an item from A. E.
Stone, of Arkansas, about bee-moths. I set a
large dish of water, and the landscape
tracts the miller, which flutters about the
lamp until it falls into the water. This pan
and lamp were in such a part of the
(with open door) so that the lamp, turned
to a dim light, reflects a little towards the place
where my bees are located, so that the light
does not reflect to the front or entrance. It
is surprising what a difference it makes if done
at the first appearance of the moth
in the spring.
I. L. MILLER.
Wyandot Co., Ohio, Sept. 27.

Poor Season for Bees.
We had a very poor honey season the past
summer due to early fall frosts, and now
have feed my whole apiary to bring them through
the winter, as we had no fall flow. Being
very busy cutting my corn and waiting on
the wheat crop, I neglected my bees when
they needed attention, and lost half a dozen
coloni\( \text{es} \). A great many colonies in this locality,
send for sample copy.

The Bees vs. Cane Sugar Question.
This is one which seems quite unwilling
to stay settled. The following editorial upon
the subject is from Gleanings in Bee-Culture:
I have received a letter from Mr. Thomas
Wm. Covent (now sojourning in California),
editor of the British Bee Journal. He has read
through the columns of that paper, has recom-
dend cane in preference to beet sugar for feeding bees. In a letter just re-
ceived, he writes:
DEAR MR. ROOT—: I have just been staying
at a fruit-cannery in the Santa Cruz
Mountains where they use nothing but guaranteed
cane sugar for canning purposes, and
their experience with beet sugar is very similar to
ours in England. It may be that the humid
climate makes something to do with it; but it is quite certain that beet sugar is bad,
not only for bees but also for preserving fruits
in general. In the laboratory it is possible
to get perfectly pure cane sugar from beets so
that, chemically, it would be identical with
that obtained from sugar cane, but in practice
it is found that there are certain

Farming by Irrigation

Is scientific and devoid of the element of chance. Crops are

BEST EXTRACTED HONEY FOR SALE

All in 60-pound tin cans.

Alfalfa Honey

This is the famous White Extracted Honey from the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey can’t get enough of the Alfalfa extracted.

Prices of Alfalfa or Basswood Honey:
A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 8 cents per pound; four or more cans, 7½ cents per pound. Basswood Honey, ¾ cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are boxed. This is all.

ABSOLUTELY PURE HONEY

The finest of their kinds produced in this country.

Read Dr. Miller’s Testimony on Alfalfa Honey:
I’ve just sampled the honey you sent, and it’s prime. Thank you. I feel that I’m something of a heretic, to sell thousands of pounds of honey of my own production and then buy honey of you for my own use. But however loyal one ought to be to the honey of his own region, there’s no denying the fact that for use in any kind of hot drink, where one prefers the more wholesome honey to sugar, the very excellent quality of alfalfa honey I have received from you is better suited than the honey of more marked flavor, according to my taste.

Mcfhenry Co., Illi.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

potash salts in sugar from beet which do not occur in those from sugar cane. Leather and beeswax have chemically the same composition, but there is a difference between them.

THOS. WM. COWAN.

It may be possible, as Mr. Cowan suggests, that the humid climate of England may have something to do with the bees. If it is not too much trouble I should like to have him give me the address of the cannery to which he refers—not that I in the least question his word, but because I should like to get a detailed statement from them, explaining why their experience with best sugar has not been satisfactory.

California vs. Australia for Honey.

Why there is so much more honey produced in California than Australia, and why a much larger number of hives can be kept in one place there than in Australia.—In Australia the highest mountain does not reach 8,000 feet, while in California they attain an altitude of from 16,000 to 18,000 feet. The white sage of the valleys precedes the black sage of the canyons, and the bees commence working in the valleys and then gradually fly higher up as the blossoms climb the mountain sides. It is much more luxuriant in the valleys than in regions not so mountainous. There is another fact that greatly extends the period of blossoms. California white sage, unlike the white sage, are in long racemes which bloom centrifugally, that is, the outside flowers, or the lower flowers, bloom earlier than the upper. This, of course, greatly prolongs the period of bloom, and, consequently, the honey season.—The Australian Bee-Bulletin.

Tarred Paper for Packing.

Last winter I had two colonies, each in a ten-frame dovetailed hive, with a half-story full of sawdust above the enameled mat, and the white bees kept the under edge of cover to the ground surrounded by a single thickness of tarred paper. This was secured by strips of wood tacked around where the paper lapped. The entrance, of course, was left open. The results were all that could be desired. The two colonies wintered perfectly, were strong in bees, stores sound and comb dry, and were the first to have supers put on. So well pleased am I with the results that I shall try the experiment on a larger scale this fall.

The tarred paper is virtually air-tight, at least in wind and water proof, but when the sun shines on it its blackness causes it to absorb much heat. I often saw bees at the entrances of these hives when my nose was found stirring in any of the others, and during the winter months I began to fear that the results would be disastrous, but they were quite the contrary.

Of course, this is only with two hives for one winter, and it is not safe to put too much dependence on the method until it has been more extensively tried.—A. C. MILLER in the American Bee-Keeper.

Uniting Bees for Wintering.

A friend inquires of G. M. Doolittle as to the best way to unite two or more weak colonies for wintering. The following conversation upon the subject is given in Gennings in Bee-Culture, Doolittle being the first speaker:

"Well, I will tell you of a plan I have used successfully for a number of years. The first thing to do is to place an empty hive where you wish a colony to stand; and if you can allow that to be where the strong weak colonies are standing, so much the better, as in this case the bees from this one will have any desire to go to any other place, as this is where they have marked their old home." "But how can I set an empty hive there when the stand is already occupied?"

"If you do this work as you should, on some day when the bees are not dying, and yet when it is not cold enough to chill bees generally, say on some cloudy day, or near summer, when the mercury stands at from
50 to 55 degrees, you will have no trouble in securing the bee hive. Stand, and taking your time in arranging the empty hive thereon.

"Having the empty hive arranged, go to the several hives having the colonies which are too crowded, and after two or three days, quite a volume of smoke at the entrance of the hive, at the same time surrounding with the dusk of your hand, or with a stick, on top of the hive.

"What do you pound on the hive for?

This pounding on the hive causes the bees to move, thus causing the honey, which is all full filling, to move, and else the bees may disgorge their load of honey back into the cells again.

"How long should I pound it on?

"One would not an assistant be good at this time?

"One would do no harm; but I generally do it about a minute and a half, as long as the hive is opened. I open the hive first, and by the hive to go in, open the hives and take a frame of comb and bees from one hive and place in the front hive, and take a frame from the next hive, placing it beside the first, and so on alternating the frames from the different hives. Reduce the empty hive filled. In doing this, select such comb from the desire, either for brood, honey, all-water comb, etc., thus putting the united colony on the best comb. Having the hive filled with comb, close it, when you will next take a frame from the first hive opened, and shake the bees off it down in front of the entrance, holding close down the bees are in or as near the entrance when leaving the comb.

Why this close holding and shaking?

"So the bees will take wing as little as possible, that they will not fall to run from the hive but that they can readily run in with the majority. Having them off the first hive, you take the bees off the next frame to the next hive, and so on, alternating in the shaking the same as in filling the hive, thus mixing the bees from the several hives all up.

Why do you wish them mixed up?

"The mixing of the bees takes the disposition away from the hives to another all out of them when filled with honey as above; for when each bee touches another it is a stranger, so that the individuality of each colony is lost, and the combined two, three or four colonies unite within two or three hours to make one colony, in which the bees feel a tenacity from itself all intruders, the same as the separate colonies did before.

"Do you always do this?

"Not quite. As soon as the bees are all shaken off theircombs, gently blow a little smoke on the bees. Then go to the next hive, enter the hive, should any be slow in doing so; and as soon as all are in the hive, place a honeycomb frame inside of it, and light it, standing the bottom out a piece from the entrance so it stands glowing over it.

"Is this done so that the next time the bees fly they will bump up against it, as it were, this causing them to know that it is a new hive; or when several of them mark the place the same as a new swarm does, after which they will adhere to it instead of wasting time over it, which bees have occupied before uniting. And to help in this matter further, it is always best to remove everything from the hive, including home-remains to entice them back."

Texas Bee-Keepers.

New Branch Office. We beg to announce the opening of a branch office and warehouse at 438 W. Houston St., San Antonio, Texas. Rates of transportation from Medina in less than car-load lots are high, and it takes a long time for a local shipment to reach Southern Texas points.

Low Freight and Quick Delivery. To secure these two necessary advantages—low freight and quick delivery—and to be better prepared to serve the interests of our Texas friends, is our reason for establishing this new branch office. No other point in Southern Texas is better adapted to serve as a distributing point than San Antonio. It has four great railroads—the Southern Pacific R. R. east and west—the International and Great Northern R. R. from Laredo up through San Antonio and Central Texas, the San Antonio and Arkansas Pass R. R., and San Antonio and Gulf R. R. It also has the American, Wells-Fargo and Pacific Express Companies.

Our Managers. We have secured as managers Mr. Udo Toepperwein, formerly of Leon Springs, and Mr. A. Y. Walton, Jr., both of whom are well known to the bee-keepers of South and Central Texas. They are also thoroughly familiar with practical bee-keeping and all matters associated with it, and any orders sent to this branch will receive prompt, careful attention.

Our Goods. As usual our motto is to furnish the best goods of the most approved pattern. We do not undertake to compete in price with all manufacturers. Bee-keepers have learned that it does not pay to buy cheap supplies, for a saving of 10 cents on the first cost of a hive may be a loss of many times this amount by getting poorly made and ill-fitting material. Every year brings us many proofs that our policy of “the best goods” is a correct one.

Our Catalog. Very few changes in prices will be made in our new catalog, so do not delay your order, but send it at once. You will be allowed a refund if lower prices are made, and in case of higher prices ruling in the new catalog, if any, you will secure the benefit by ordering now. Catalog and estimates may be had by applying to the address given below.

Our Invitation. Whenever you visit San Antonio you are invited to call at our office and make it your headquarters. Here you will find a display of Aparian Supplies not equaled elsewhere in Texas. You will also find on file the leading bee-journals to pass pleasantly your leisure time.

Spanish Catalog. Some of you may read Spanish, or have a bee-keeping friend who does. If so, call for our Spanish catalog. It’s sent free.

Branch Office: THE A. I. ROOT CO., San Antonio, Texas, 438 West Houston Street, TOEPPEWEREIN & WALTON, Managers.

The Cold Snap.—Did it catch you! No doubt it did a good many. The latter part of October was so summer-like that it was easy to think that freezing weather might be far away, and so some last preparations for cold weather were put off from day to day with the thought that there was no immediate need for haste until the weather became at least a little colder. But that "little colder" weather never came. From summer weather there was a sudden jump right into winter weather. Here in the north Illinois we had in the last of October a temperature of 90 degrees. All at once a cold west wind set in the night of Nov. 3, and by morning the thermometer registered 12 degrees.

Now, don't you wish that colony short of stores had been attended to in September? Well, look out another year.

Long Smellers.—A clipping from the Belfast Blazo, which has been received, contains among other things the following:

Mr. Ballard says that a honey-bee can smell clover honey two miles away. He cites an instance that once the nearest clover to his bees was over a mountain in the Hell Hollow district, two miles away, and his bees all went there to gather honey. He says if you go out in the woods half a mile from a hive and burn some honey-comb that within ten minutes the bees will be attracted there from the hive by the sense of smell, if the wind is right. But some of the ways of the honey-bee are past finding out.

This is a case of correct pr. mines, with a false conclusion drawn therefrom. It is true that bees will find a clover-field two miles from their home, and that in a few minutes they will find burning honey-comb within a half mile; but it by no means follows that they can smell anything two miles, or even half a mile, away. It would be just as reasonable to say that when a man went hunting and shot a squirrel two miles from home he saw the squirrel when two miles away. Bees are good hunters rather than long smellers.

Profits of Bee-Keeping are sometimes painted in rather bright colors, even when there is no real intention to mislead. Referring to some remarks on page 570 of this journal, in which some very bright painting in the August number of the American Bee-Keeper was commented upon, the editor of that journal says:

There can be no doubt that the glowing pictures sometimes painted of bee-culture and its profits are open to criticism. The beginning hobbyist—may in this way be led to expect too much; yet, with reference to the question in hand, we think no bee-keeper of experience would be inclined to regard $5.00 per colony as big returns. It should always be borne in mind that any business enterprise is subject to adverse conditions and casualties. Then, there is a limit of one's personal capabilities to be taken into consideration. One apiarist can not properly attend to several apiaries; expense increases in proportion with the number of hives he attends. One colony might easily produce 100 pounds of comb honey. This might readily amount to several dollars in the year. It can be shown that nectar, as a rule, is gathered in equal ratio. One colony might easily produce 100 pounds of comb honey. QUEEN-REARING—IN-BREEDING.

"In rearing queens is in-breeding objectionable?"

Mrs. H. G. Acklin, of Minnesota—There are so many present who are much more extensive queen-breeders than myself, that I would rather hear an expression from them. I think it is objectionable. We get queens from several different breeders and bring into our apiary every year.

Dr. Mason—Then your practice is not to in-breed?

Mrs. Acklin—Yes.

Dr. Mason—What makes you think it is objectionable?

Mrs. Acklin—I really don’t know. In getting new queens you change your stock, of course, and get good qualities. In getting queens from different breeders and bringing in the best drones from your best colonies, you get your best stock. Of course, if you have any bad qualities in your queens at home you can get them out to a certain extent. We watch our queens very closely.

Dr. Mason—Why not dispose of the queens that you have that have bad qualities, and keep those that have the good, and breed from those right along?

Mrs. Acklin—I don’t know as I am able to answer that.

Mr. Benton—It doesn’t seem to me that there is the least objection to continued close in-and-in breeding, of itself. That means, of itself, nothing. In other words, if you want to improve your stock by the process of inbreeding, you have to take great care to select the queens, and select the queens to breed drones with reference to the qualities which they possess and which you wish to perpetuate and fix in the progeny, and to avoid weaknesses, select such queens as mothers of the drones as will avoid weaknesses that are inherent in that strain that you are breeding from. From in-and-in breeding we can fix a type, or character, which we could not do by constantly bringing in different strains or crosses. In all our hybrid animals the types have been established. We have a beef animal; we have a milk animal; we have a sheep that gives us long wool, and fowls that produce eggs, others produce meat, and so on, and in every instance all of those particular-purpose animals have been produced by careful, intelligent in-and-in breeding. From the very earliest start, therefore, I claim that in-and-in breeding is not harmful, but it is the lack of care in operating to apply it that results badly. When we have a strain with a weakness and we do not bring in any other stock at all, we do not breed intelligently enough to fix the stronger points in the breed, and eventually that strain will run out.

Mr. West—In regard to in-and-in breeding, the question I was going to ask is, How much does that mean? Can we confine in-and-in breeding to bees with a queen of the same individual hive and let that constitute an apiary, and use the drones from that individual hive from year to year and remove all other colonies from the place? Would it be beneficial to in-and-in breed in that way?

Mr. Benton—I don’t suppose such a case occurs at all, and in actual practice there is no such constant in-and-in breeding. I really think it has been held up as a bugbear, and people that engaged in breeding in-and-in were not really doing so, because there was such constant out-crossing, and I don’t think that we would be able, with the greatest care, to confine to as close in-breeding as Mr. West refers to. When we speak of it generally, I think it refers to close breeding more than in-and-in breeding, confining drone-production and using perhaps the same queen mother constantly.

Dr. Mason—Perhaps 20 years ago I had a brother who kept bees, and I started in with fifteen colonies that he gave me. He lived fifteen miles from anybody that kept bees. He got a good queen and he never bought any more, but he was constantly breeding in-and-in, and showed poor qualities, and he had the best honey-gatherers I ever knew. He kept the bees pure. They were gentle and as nice as one wishes to see. That is what makes me believe in in-and-in breeding. They were Italian bees.

Mr. Benton—That person who obtained that trio of Buff Cochins must have gotten two of Buff Cochin stock, and then probably has selected intelligently. Now, Mr. Benton, I have never been particularly interested in the question of whether there had been some trouble with the stock, like leg weakness for instance, it is very doubtful if he could get a good breed. I think the proof of the pudding is on the other. I hope that we will get rid of this whole idea of Darwin, that cross-fertilization is necessary to perpetuate the race. There is nothing in it.

Mr. Abbott—I feel as if I wanted to vote on this. I am surprised to know that a man who has given as much attention to science as Mr. Benton has, is so in accord with the view that I have held for years. In theory it has been combated by poultry people, and by everybody, in fact, wherever I have expressed it. This idea, which origin- ated in Darwinian days, has been repeated without limit since that time, has gotten such a hold in the world that it is pretty hard to get it out of the minds of the people. In fact, some people think they ought to be against in-and-in breeding because it is forbidden in the Bible. They sometimes give that as a reason. But, so far as I have heard, the best illustrations of the result of in-and-in breeding is found in the State of New York. There is a man who originated what is known as the American Holderness cattle, and those cattle originated from a single cow that came from the Holderness cattle of England, some 40 years ago, and which is now a very fine, and all the cattle of that herd have the blood in them, said to be the finest herd of cattle on this continent. That man has used intelligent in-and-in-breeding, and he has taken the bad qualities, eliminated them as fast as he came in contact with them, and bred in the good qualities, and that is what I contend for. In the case of course, who have males to sell, would like to have you believe that it is a good thing to send across the continent and breed in-and-in order to keep your poultry healthy. I have been doing myself just what Dr. Mason says his neighbor has been doing, breeding Golden Wyandottes, and I haven’t had any new blood for years, and I am quite sure that if I live for 50 years more (and I hope I will 100), I am quite sure that there will be no new blood go into that stock, but I kill every roopy hen, I exterminate every diseased rooster, and wipe out with the hatchet all tendency to disease; I don’t tamper with what is good in the breed, and I don’t bury it beneath the ground out of sight. I believe that if bee-keepers can control bee-fertilization some time in the future, that they can get the very best results. I hope that I will get rid of this whole idea of Darwin, that cross-fertilization is necessary to perpetuate the race. There is nothing in it.
AMERICAN BEE JOURNAL

Nov. 14, 1901.

duced Rose Comb White Minorcas, so I started with that jet-black Male Minorca, and I've now found with the Minorca hens. Now, after two or three generations, I get hens that are pretty nearly white all over, by selection. I select the lightest black which I get and try to eliminate in that way. In a few generations I secured a fowl that was entirely white, and reproduced itself and had a pure rose comb, the true Minorca type, with the jet-black male or any other type at all, and produced with a male that was jet black, and whose progeny were always jet black. When I look at this, I can throw the race back, but that was only the exception, and that was done in and-in-breeding. After this first cross between the jet-black male and the white female I didn't get any other blood into them.

J. H. M. Cook, of New York—What relation is the drone, or a hive to the virgin queen produced in that hive? What true relation do they hold to each other?

Mr. Benton—You might say halfbrothers.

Dr. Miller—I do believe that there has been a great deal of misappréhension on this subject, and yet amongst insect workers I don't think that Mr. Abbott has been so much alone as perhaps he has felt. He has had good company. I believe that all intelligent breeders will tell you that if you put down the dictum that in-breeding must not be allowed, that it puts an end to nearly all improvement in breeding. It should be understood that in-breeding will perpetuate the good qualities, and it is also the thing through which you will perpetuate the bad qualities. It is a false view that old stock should and to understand that fresh blood introduced will be a good thing, and that the cross-breeding after all is for the average layman the safe thing rather than to continue to breed exactly the same stock straight along. I believe the old view, just as bad as it may be, is the safer view. There are many who head the idea that he doesn't need to pay the least attention in in-breeding, and that no harm can come from that, you are going to damage that man beyond computation.

Mrs. Ackin—We get our queens from different queen breeders occasionally to try them, and we test them two years anyway before we take them in, but we always get the same strain of bee; we don't make a cross at all, and I suppose that there always is more or less in-breeding, although we try not many times we breed from the same bees.

Mr. McEvoy—I would like to have Mr. Benton's opinion on the subject of crossing good Italians with Carniolans, are you going to damage a line by crossing?

Adjourned to 1:30 p.m.

WEDNESDAY AFTERNOON SESSION.

The convention was called to order at 1:30 o'clock by Pres. Root, but, owing to a meeting of the Board of Directors, which was held at Mr. York to the chair. The question asked by Mr. McEvoy previous to adjournment was then taken up.

Mr. Benton—I have never crossed Carniolans with Italians, so that my opinion in that matter would have to be theoretical, and from what others have told me. As I was rear- ing Carniolans, I have found that only a few of the matings and have had Italians in another, and not desiring to cross the two races, I haven't attempted any experiments in that direction. However, I have had very favorable reports of such crosses, and I see no reason why they should not be successful. The general type of the two races is alike, regards the form of the race, but in their general economy in every way. They are not so radically different as the bees of Europe and the bees of the Orient. The Carniolan is an entirely different type, and to cross an Eastern bee with the races native to Europe, would be like crossing, we will say, a race-horse and a cart-horse; some such comparison might be made, but when you come to crossing Italian and the Carniolan bees there is not that radical departure from the general type, and I see no reason why the two races would not amalgamate well, and having made the first direct cross I would then myself close to the Carniolan, and then make any other direct cross, but breed from the best constantly. I case I brought in any fresh blood after that first cross, I believe the race would be so close to the Carniolan, simply because of the qualities that they possess, but I believe that the Italian would introduce a disposition in the bees perhaps to breed a little bit less during the honey-dearth than the Carniolans, and in some localities that might be beneficial, provided, of course, you could get them to do it, and to prepare for a future harvest without having to feed them too long. The Italians, when the honey harvest lets up, are less inclined to work close to the Carniolans. The Carniolans are continually breeding during this time. That is a good quality, provided those bees that are produced then can be brought into a second harvesting. There is no succeeding harvest to put them into immediately, it would hardly pay to feed them up to the time of the next harvest, and at the same time I think such crossing would be beneficial.

Dr. Mason—I had two of Mr. Benton's queens that I crossed with Italians, and I think they made the crossest bees in the country, outside of Mr. Cogshall's apiaries.

Mr. Benton—It seems to me that would be rather an exceptional condition, and, as I suggested, by keeping close to the first cross the gentleness would preserve in the main.

HIVE-COVERS FOR SUMMER AND WINTER.

Have we a satisfactory hive-cover? Is there one made with a dead-air space so as to be warm for winter and cool for summer, and that will not warp or twist?

Mr. Heise—When that question was raised I was wondering why any one wanted a warm hive-cover in winter, all that I have found for it is to keep dry the packing that I expect to keep the bees warm with. All that I use is a half-inch board for the roof, packed with dry straw, which makes it cooler in the summer. I provide my bees with sufficient packing under the cover, and I don't care much what the cover is like so long as it keeps the packing dry.

G. F. Davidson—We use in Texas a flat cover without an air-space, but I don't think we have ever found one that would not warp. We need an air-space in the summer to keep the combs from melting down, but we never have found one that would last through the winter. We have used the flat board, and the covers that were made of three different boards, "auxiliary covers" they used to call them, in Texas. We have there about six or seven months of sunshine, without any rain on them.

Mr. Betsinger—I have a cover that doesn't warp or twist. It is a simple frame box with a tin cover telescoped on top of the hive, and it is so made that the cover doesn't come down to the board within half an inch. Now the telescope cover is half an inch larger every way than the hive. That cover, won't warp or twist I don't care where you put it. And it is cool in the summer; I never had combs melt under it. For experiment I had made another case just like the cover with the cover fitted that left a dead-air space and found that the bees would not melt. A telescope cover lets the air all around the interior of the hive, and although the sun shines directly on it, the bees are cool. The covers will cost about 50 cents apiece if you make them right. A 14x20 sheet of tin makes the cover.

As Mr. York was called out to confer with the Board of Directors at this time, Mr. Heise was requested to take the chair.

Mr. Wilcox—I have a gable-roof cover that sheds the water and is a good roof on the hive, and I made a cover as Mr. Betsinger has described, which also sheds water. Either will do well, but to guard against the melting of comb in very hot weather you need the double thickness with the air-space between, in some localities, but I would rather have a cover, if possible, that would make a hive warmer and make it cool. I think we are troubled more with cold weather than warm weather, but the difficulty has been with flat covers—either would do well. I have 300 ozee in around the hive, unless you have a gable cover, and I want something better if there is any.

Mr. Heise—I would like to have the next person who takes up the subject of hive-covers to tell us what is a dead-air space.

Mr. Wilcox—If you have a gable cover it is easy enough to lay a flat cover inside of that, and there will be a dead-air space. A dead-air space is simply the thickness between two quarts of boards where the air cannot circulate.

Mr. Betsinger—That point is very important. We don't want dead air; we want live air; we want live air, we want live summer air.

Mr. Wilcox—I want to criticise that. He says we don't want it. It depends upon what result he desires to attain. The dead-air space to keep the cold out; you have to let the cold air in, in hot weather.

Mr. Betsinger—a dead-air space is colder than no space at all. When the heat is great, it will penetrate through one wall two walls. The interior of the hive is dryer where the sun can shine on one single wall.
shine, and all the heat comes from the bees.

HAVING A SWARM WITH A NUCLEUS.

"When a swarm issues with a clipped queen, if the hive with the clipped queen be removed and replaced by a hive containing a virgin queen, you will find that returning swarm kill the queen in the nucleus?"

W. L. Coggshall—If you get foreign bees with a strange queen, they will kill it invariably.

Dr. Mason—That is, if it is a swarm that has gone out, and they come back to a nucleus that has a queen, they will kill it instead.

W. L. Coggshall—Strange bees are quite apt to kill another queen.

Mr. Betsinger—My opinion is that they wouldn't kill the queen, for the very reason that the nucleus wouldn't let them.

Mr. Wilcox—My experience is that they will not, nine times out of ten.

Mr. West—if I had swarming that way, with a nucleus, after removing the old colony, when the swarm returns I would shake the nucleus bees on to the ground, and let them return with the swarm. When the swarm is returning the old queen has been caged, and removed. Shake the nucleus bees, queen and all—and let them all run in together, and all is well.

Mr. McEvoy—I don't think you can do as well if you talk a whole afternoon to discuss the question.

Mr. Tyrrell—I would like to ask if a little smoke applied to that nucleus wouldn't produce the same effect as shaking the nucleus bees.

Mr. Wilcox—Before the others returned I have often poured them down from the hiving-box, smoked the nucleus, and united them with weak swarms.

Mr. Heise—When that swarm returns, having lost their queen, there is very little left to join them. They will accept almost anything—glad to get a home.

Mr. Mason—if Mr. Betsinger is correct that the queen, and the nucleus will protect the queen, and you spoke of a nucleus, that takes the protect out of them, doesn't it?

KNOWING WHETHER A VIRGIN QUEEN IS PRESENT.

"How can I tell whether there is a virgin queen in a hive if I cannot find her?"

F. J. Miller—There is no way that I know except to wait a few days and look for larve or eggs.

W. L. Coggshall—You will see the bottom of the cells polished out where the brood-nest is.

Mr. Coggshall—You would see a frame of brood in it and wait three days.

Mr. Davidson—They make a queenless noise.

Mr. Benton—Watch the entrance just at sundown after they have lost their virgin queen and they will be running excitedly about seeking for the queen. I want to ask Mr. Coggshall if the bees begin to polish out these worker-cells before the time approaches for the queen to begin laying eggs. They will begin to remove the honey and polish out the cells, but they will not do it until near the time she is about to lay. The point would be, I suppose, not to lose any time waiting for that time.

W. L. Coggshall—that would give you warning that she is there.

SELECTING LARVE FOR QUEEN-REARING.

"When a colony is made queenless will the bees, in their haste to rear a successor, select larve too old to secure the best results?"

Mr. Duffield—I think it is very seldom that the bees select that kind of larve. I have noticed it only a few times in my experience with bees, that they have selected the 'right old' larve. I have seen some hatched out about the ninth day and it didn't look as well as it would if reared from younger larve. I think that it is very seldom that the bees make a mistake.

Mr. Benton—I agree with Mr. Davidson. The conditions under which they do select rather too old larve seem to be when the colony is weakened by any means; for instance, it is a small colony, or what might be called only a nucleus, but a colony in good condition and gaining honey rapidly, they rarely make a mistake and get the larve too old.

Mr. West—in regard to removing a queen, if the bees, I have an apiary of about 80 colonies that about June 1 and about the time the swarm begins, I remove the queens from these colonies of bees and on about the 10th day I again rear about as many queens again as we need, and we make a selection again by using the best queens according to our judgment. I have never had better results in any apiary than I have had by getting my queens in this way.

HOW LONG TO REAR A QUEEN?

"How long from the laying of the egg to the emerging of the queen?"

Mr. West—10 days, generally.

Mr. Betsinger—It varies from 15 to 17. The largest colonies getting the most honey will produce queens that will mature quicker than smaller colonies with less honey.

Mr. West—if colonies are in a normal condition and everything favorable it will not vary from 16 days.

Mr. Benton—It is a question of continuity of heat in the hive, and I agree with Mr. McEvoy. The time the larve is there varies one way or the other for a number of hours. It may be less than 16 days or a little more than 16 days, but in some cases to lay the cells where the heat is continuous. I think the average time is about 16 days. We find the worker-bees sometimes comes out in 10 days and very commonly in continuous heat in the latitude of Washington they emerge on the 20th day from the time the egg is laid, showing it is due to steady heat which develops the larve.

YIELD OF HONEY PER COLONY.

"Which will give the greatest yield, a colony of bees that produced the same colony if it does not swarm?"

Mr. Hershiser—It depends entirely upon how early in the season you get the swarm.
Contributed Articles.

Unfinished Sections in the Fall—How to Obviate Them.

By G. M. Doolittle.

A correspondent writes thus: "Nearly every fall I have had more or less trouble from the wax- secretion. I have lost a number of colonies and especialy combs of honey, and it makes us less work in handling hives and extra fixtures, and it saves us considerable trouble.

W. L. Coggshall—From what Mr. Betsinger said about feeding, you might infer that I feed sugar to stimulate the bees and the amount of sugar in my life to stimulate.

can get more from the swarm and the two or three combs the queen have an apary of 80 to 100 colonies, and all the bees we need to gather the surplus honey of the field, I prefer not to have any increase to amount to anything, before the old colony will gather honey, and it makes us less work in handling hives and extra fixtures, and it saves us considerable trouble.

W. L. Coggsahl—From what Mr. Betsinger said about feeding, you might infer that I feed sugar to stimulate the bees and the amount of sugar in my life to stimulate.

WAX-SECRETION.

"Is wax secretion voluntary or involuntary?"

Mr. Bentsinger—Largely voluntary.

Mr. Betsinger—I'd like to know why.

Mr. Bentson—Simply this: If we give a colony its combs there is not a great secretion of wax, even though they are gathering honey rapidly. If, on the other hand we give the bees to do hive or hive it in a empty hive, it has its combs to build, and it will use quantities of honey that otherwise would be left. The secretion of wax to build those combs. Therefore, I regard it as voluntary, since in the one instance they have used no wax to amount to anything, and in the other they have used a good deal when there was the need of it.

Mr. Betsinger—You plant a little garden on the ground and it comes up and grows. Is that voluntary or involuntary? You can hold it back or you can force it. So it is with bees. They secrete wax and they cannot help it so long as they gather honey, but you can increase that by feeding. But they are compelled to secrete wax as long as they live and gather honey.

(Continued next week.)

The following are sections in the fall, while, had we left them as they were, all would have been finished, and we and the bees have been happy.

My plan of operation to secure all capped sections or as nearly so as may be, when the season closes, is as follows: When the bees show by building bits of comb here and there about the hive, and by lengthening the cells along the top bars of the frames, that they are securing honey from the fields. I put on sections to the amount of the smallest capacity of one of my surplus arrangements—or say 24 to 25 pounds—and leave them thus until the bees are fairly at work in them. When I add more room to the amount of one-half that put on at first, if possible; and, if not, the smallest possible amount consistent with the surplus arrangement I use, generally putting this last fast under the one the bees are already nicely at work in, if this room is needed during the first half of the probable surplus yield. When more room seems likely to be needed, by finding that the room now on is fully occupied, it is given by placing wide frames of sections containing full sheets of extra thin comb foundation at the sides of those sections the bees are already at work in; or, if our surplus arrangement will not admit of doing this, by placing these sections over those already occupied.

By working according to this last named plan, the bees always have plenty of room so that they are never crowded, yet it is given in such a way that they will always complete all of the sections under way or between, which were fully occupied when this latter room is given.

By the way more room is needed, the sections first given are ready to come off when, as they are taken off, more room is given at the sides or top, as the case may be, and thus the bees are kept finishing sections the nearest over the broad chamber and commencing in those further away. In this way the season will close with a minimum number of unfinished sections, instead of a maximum number, as is generally the case where the old way of tiering up is used.

I am well aware that we used to argue that by putting the empty sections between those already occupied and the broad nest, the bees were irritated by greater activity, and, as a result of this activity, a greater result in comb honey would be secured, but after trying both plans side by side for several years, I can see no difference in the yield of honey in thoroughly good years, while in fall to poor years the plan above outlined gives much the greater yield of marketable honey.

Gonnagad Co., N. Y.
No. 2.—APICULTURE AS A BUSINESS.
Some Colorado Conditions—Average Yield—Prices and Outcome.

By R. C. ATKIN.

I WANT the ear of all apiarists who are in apiculture to make it a business. Some few have been very successful, but those whose motive is for either home consumption or for market, surely should consider the cost. I shall write mainly for Western conditions, and, for several reasons, principal among which are, 1st, I am more familiar with conditions here; 2d, more people in the West are engaged in this business; 3d, the Western apiarist has more difficult problems to solve.

As indicated in No. 1, not even in Colorado, where alfalfa, sweet clover, and clover abound, do we have a sure crop. Each Eastern apiarist thinking of coming here to get the advantage of a field where he can have a honey crop every year, would better step and learn if his ideas are right. My field, and the county in general, as well as other counties and localities in the State, have both alfalfa and sweet clover in similar quantities, and I do not believe that either will give some surplus honey should it yield freely.

The trouble with alfalfa is this: Being in growth similar to sweet clover, a strong, rank plant, though not so large as to entangle honeybees, allows it to mature to the extent of getting into full bloom or any ripeness of stems, or parts of stems, before the honeybees learn how to get at affluence. If we could force the stems become hard and woody, so much that stock will not eat these coarse stems unless forced to do so by very scant feeding; hence, the rule is to cut for hay just as the bloom begins to appear. In this slow-ripening clover, spring is a little later than that for alfalfa, in Iowa, central Illinois, Ohio and Indiana, probably about two weeks. The southern parts of this State will be from 2 to 3 weeks earlier than here, and lower altitudes in the same general line.

Alfalfa delights and grows rapidly in a moist but not wet soil. A big rain or irrigation that fills the soil with moisture puts it in prime condition for rapid growth in hot, sunny days. In my location periods of 80° to 90° and nights, many nights in April coming close to frost, even in May and June quite cool. The fact is, that, as a rule, all the year through we have cool nights, and, often, some frost appears in places almost every month. However, while the nights are cool the days are warm, the rapid and extreme changes in temperature between midday and midnight being much greater than in lower altitudes. In May and June the days become quite hot, and then the alfalfa "gets a move on it" and grows rapidly. In my location one can see the honeybees gathering nectar averaging the date of June 15, ranging from the 10th to the 20th.

About the time the first blossoms begin to appear on the alfalfa the first honey flow is in. Out on the first hand the last fields are cut they have attained just about full bloom, hence we have had from one to two weeks of fair honey-flow from this source—the only bloom and source at this season. I say fair flow—alfalfa delight and grows freely, but never known it to give the rapid yields obtained from white clover and basswood, especially the latter. This slowness of the flow and the limited time of its duration, often find us with the brood-combs filled and possibly just a start in the supers, and also the swarming-fever on, when the first flow is about over. So far as the great and vast acreage of alfalfa is concerned, you see it has gone into hay, a very small percent of it over maturing to sufficient bloom to yield any nectar. As soon as the first cutting of hay has been finished, the mower begins where it started first, and in June and July the growth is so rapid with favorable seasons I have known the second cutting to be in July. It is in the first, though usually a longer time intervenes. Unless delayed, the farmer never lets his hay alfalfa bloom.

But there are the fence-rows, ditch-banks and here and there weedy places and plants that continue in bloom. Also, there are fields of a certain size that have had their hay cut and put away. The heavy, tough alfalfa roots are very hard to cut with a plow, and usually enough of the plow by slipping by it, in spite of three and four horse-power, to make quite a great deal of surface breaking. The honey is not any less, it is merely scattering a field here and there, and thin in the field, so our flow from this is seldom at all free.

The last of July and the main part of August is wheat harvest time here, more being harvested in August than in July, but, bear in mind that these dates vary with latitude and altitude, but in relation to each other and general application to apiculture, the principles and facts apply. In some localities and years the conditions may be much different. In Colorado the bloom to the maturity of seed is several weeks, ripe seed and bloom being on the plant at the same time, more so than red clover, but not so much as sweet clover.

You see, under these conditions we watch anxiously for the flowering of this clover, and realize the importance of having available a plentiful quantity of alfalfa, clover, and others for a scarcity of grappers and for favorable nectar-secretin weather, and hope the farmers will not push having too rapidly.

Right with the first alfalfa flow comes swarming. The combs that swarms during the first two weeks of the flow is almost sure to do so before the first super is full, many before it is even started. Now see the drooping hopes of the apiarist—super work only just getting started, bees swarming and, what is more, the bloom and source of nectar rapidly falling before the mowing machines.

It will be about July 15—one month from the beginning of the alfalfa bloom—before sweet clover comes on. Having failed of any paying surplus from the first flow (and this is common), we watch anxiously for a strengthening or continue of the flow from the sparse, scattering alfalfa in the corners and wheat-fields, and for the opening of sweet clover. If the swarming alfalfa has had a fair supply of nectar and pollen to give to the bees, then this is the time to watch for a super crop of alfalfa, and there is ordinarily about every two to three weeks on very strong colonies, and one in three to six weeks on the medium colonies. Contrast this, if you will, with, getting a hundred pounds surplus in a two to four days, if the flow, and any experienced apiarist knows such conditions will not give fair results, and satisfactory and profitable yields, without the best of management. For ten years I have had just such experiences almost constantly, slow and intermission of flow, a condition that does not ask for a 15- to 25-pound surplus to almost a hundred-pound yield. I recall from memory such yields as 10, 20, 25, 40, 75 and 80 pounds—an average yield for 10 years of about 40 pounds.

Here I must state that such yields have not been obtained where swarming and much increase have been allowed. My yields for my locality, as herein given, have been far in excess of the average bee-keeper in this vicinity, or even in this county and adjoining ones. I do not allow swarming, nor do I allow any increase in the colony to the amount of one section—either liquid or super. This is an average yield for the past ten years in this county, in the hands of any but those having more than average knowledge of the business and necessary facilities. I think there is not ex-
Questions and Answers

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.
(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—Editors.)

Moving Bees.

1. I wish to move several colonies a distance of 30 or 35 miles, either by rail or horses. They are packed for winter on the summer stands, are in 8-frame, staple-spaced hives, with one deep box of packing all around and chalk on top the depth of the supers. The cases are the same size as the stand. If I leave the hive-entrance open the full width, and fasten wire-screen over the case, entrance, and to hive-stand, will top ventilation be necessary if moved now or in March?

2. Would frames need fastening if moved on bob-sleighs?

3. Would they have to be moved at night during cold weather?

4. Would it be safe to move them now, or would they do better moved toward spring, say February or March?

New York.

Answers—1. Something depends on the kind of bottom-board and entrance. With a deep bottom-board and a large entrance, there would be no need of top ventilation. With an entrance box 4 inches, there is no use to the left entrance, and therefore there might be danger to a strong colony.

2. Staple-spaced frames, or any fixed-distance frames, ought to need fastening.

3. They could be moved in daylight.

4. While they might be safely moved now, there might be some advantage in moving them in early spring. The combs would be lighter then and less likely to break. There would be fewer chances of loss by thieves, and better chance for the bees to see the sunlight and move away and work back. We think it important that bees should have a chance to fly off after being moved, and they would probably be able to fly sooner in March than in December.

Queens for Breeding Purposes.

I have a lot of queens all reared from the same mother; of course, the mother's bees are nicely marked and are fine gatherers. But one of the young queen's bees show to very finely marked and are extra-fine gatherers. Now, if one of the queens had to be used as a breeder—the young queen just mentioned or the mother—which would be the better one to use?

If the young queen is used as a breeder the drones will be principally of her sisters, and if the old queen is used as a breeder the drones will be of her daughters.

Now, if you think of this, a new queen to breed from please let me know where I can get one that is second to none in every respect.

South Carolina.

Answers—1. Your question is not an easy one. The rule that has been generally given is to breed from the best. Mr. F. B. Simpson, who seems to be unusually well informed in the business of breeding, says that a queen whose workers are phenomally good, it is better to breed from one which is only a little above the average, providing the breeder is from a mother whose queen progeny are nearly uniform in character, and is generally of an average good being. In this case I think I should breed from both the old and the young queen. The drones prevailing in the apiary, as you intimate, will be the sons of the sisters of the young queen, and will be practically the same blood as the young queen. Assuming that these are the drones that will be used, if you breed from the young queen, her daughters will breed drones that will be practically the same blood as themselves. The assumption, however, that the said drones will be the ones used, is, in most cases, not very reliable. The drones from surrounding apiaries within a radius of a mile or more must be taken into account. It depends much upon the character of your present stock as to whether or not it may be a gain to get a new queen. If your stock is not good, you could improve by fresh purchase. But I could not direct you where to purchase, and for two reasons. It would have been much better for you, had you a fresh slock 10 years, so that you could have a new bee-paper to have one special breeder pointed out as the one from whom purchases should be made. In the second place, even if the publishers should allow it, I could not tell you where to get the very best for the simple reason that I do not know. There are, no doubt, many who are trying to rear good queens, and it is possible that a large portion of them may be nearly on equal footing.

Arranging the Hives in an Apiary.

I am going to move 100 colonies of bees to the country this winter. How would you arrange them? I will have plenty of shade and ground. I want to avoid the loss of virgin queens as much as possible.

Alabama.

Answer—With plenty of ground, you could place them regularly in rows a rod apart, each hive a rod from the nearest. That would make it all right for the virgin queens, but it would make it more difficult for the bee-keepers. In this case, if you get at a satisfactory answer, suppose we talk the matter over a little. It is not so much the distance between hives that allows a bee to find its own hive as it is other things. Set a hundred colonies of bees in a row, a perfectly level plain, not a tree, bush, stump or anything of the kind in sight, and if the hives are a rod apart there will probably be more danger of bees getting into the wrong hive than there would be in a dense, natural grove with the hives only a foot apart. Let two hives be placed touching each other, and if no other hives are about there will be no danger of bees getting into the wrong hive. Have two nuclei in the same hive with entrances facing the same way and only six inches apart, and there is little danger that the bees of the right side will enter the left side. I understand this we can take advantage of it in placing our hives. Where shade is plenty, as you say it is in your case, there are trees present to help mark locations, and a little danger of confusion if hives influence each other only six feet apart. Suppose we place them so. As already said, there is no danger of mistake if two hives are set close side by side, by the side of each hive already placed let us set another. Now that the bees can reach in and out, and for a distance a little farther, we think that the other group, that is, the backs of the second pair are placed against the backs of the first pair. Now we have our hives placed in groups of four, and if there is any mistake as to entering wrong hives, it will not be that are the confusion. If the bees have their own group but that it will enter the hive corresponding to its own hive in another group. This method of grouping I have used for years, and you will see that it allows you to have 100 colonies on a given piece of ground, with just as much shade as though you had only 25 placed singly on the same ground.
1. I have a few colonies of bees I bought one year ago. I robbed them the last of June and got 17 pounds of comb honey per colony; and again the last of July I got 26 pounds of comb in another colony; but the last time I robbed them they all fought and stung me awfully. Now I want to know why they all fought me so the last time I robbed when the first time I did not get stung at all? How can I manage to avoid stings in the future?  
2. When is the best time to rob the bees?  
3. Why did I have so few swarms this year?  
4. When is the time to transfer?  

**ANSWERS.—1.** The great probability is that when you took the honey from them in the first time in June, they were at that time too young to rob freely. As long as a larva is quite good-natured and liberal, caring little how much honey you take away. When you attempted to repeat the operation the last of July, it is likely they were getting little or nothing from the fields, with plenty of time and disposition to resent any parroting of their hard-earned stores. Even if they did considerable storing afterwards, there may have been a hull in the harvest the latter part of July. It is also possible that you were not quite so careful the second time about exposing honey in the hottest weather. If it is some with bees in a time of scarcity, avoid having hives open longer than is absolutely necessary, and take great pains not to have supers of honey exposed to the robbers. It may also be a little safer to rob at this coming of time, by that the efforts of any bees with ambition to obtain a reputation as highway robbers.  
2. Better take away all surplus as soon as the flow ceases, or to leave it however no more than suflfices for their daily needs. Something can be told about this when you find that the amount of honey in the supers is not on the increase, and at such times the very fact that the bees are unusually cross and inclined to rob may make you suspect that they are not gaining in stores.  
3. Very likely the character of the season had something to do with their not swarming, although other causes may have prevailed. Without knowing any more particulars, it would be incorrect to say what.  
4. You may transfer in fruit-bloom, or three weeks after the first swarm.

dreams and their meaning to himself. But, no, he must tell.
I hear the show of boasting may have been present to
the already unholy and sensitive nature of his dream. Was it kindly, then, or mosteful, for him to tell of the
second dream? The less was this true in that it reached to
the heart of the one who was to become subject to the son
of those wicked brothers—and they were horribly wretched—were
in the way of some potent influences which must have fed and
nourished powerfully the rancor, hate and jealousy that res-
sulted from them.
Joseph's misfortunes certainly developed in him a char-
acter magnificent almost beyond compare. That the brothers
were won in part from their evil thoughts and practices is as
surely true. Maybe many of us are most fortunate in the
irritating, vexations, experiences that come to form us.

THE SUNDAY-SCHOOL.

I find a rich treat in the Sunday-school. My father al-
ways went with me to Sunday-school. He was for years
the superintendent. I early learned to love the study and dis-
sions. How different it might have been had not my father
cared for these Sunday privileges. Nothing could keep any
father away. How could I but learn to respect this service? I have
always followed in my father's steps. My children were the
companions of myself and wife as we almost invariably went
each Sunday to study that masterpiece in all literature.

Today my son teaches regularly a large class in a large
and influential Sunday-school. A little son has just come to
the front in this fairly large Sunday-school. I am in the thought that "Little
Albert" will grow up to attend and love the Sunday-school and all the blessed teachings that it hands over to its patrons.
In just such influences lies the safety of our children. Such teachings give to our nation a grand citizenship.
We stood appalled before the last act of the anarchist. Anarchy
can not even sprout in the blessed seed-bed of the Sunday-school.

I am teacher of a large Sunday-school Bible class of over 30.
There are seldom less than that number in the class.
Yesterday we had a gentleman and his wife with us who are
not wont to come. The father told me that he did not know
it was so interesting. He assured me that they would come
regularly if the subject interested them. They have three bright boys.
One, the oldest, a very promising boy in many ways, with two

other boys, ran away last year, and were gone, to the great
sorrow and agony of the parents. In my home, I thought,
I replace any wish to do so with a better ambition. But if we
wish our children to love and benefit by the school we
must love and benefit by it ourselves. We often need its beneficent
influence fully as much as our children do.

Oh, how glad I am that my father loved such things!
How richly have his tendencies and habits in all these good
ways taken hold of my own life, and, through me, they have
been passed on to bless my children and my grandchildren.
Sunday-school teaching is more to the point to give us
with our children to a good Sunday-school?

A MINING TOWN SUNDAY-SCHOOL.

As a child I was never strong. While I remember my col-
lege life as most delightful and as the best part of my whole
life, my poor health, however, was a constant menace to its
continuance. So this life was not all roses.

I stepped from college broken in health, and came to
California to mend it. I secured a school in a rough
mountain town. There was no church there, and, as I have
ever been the only professional Christian. The children, how-
ever, were just as interesting as others, and, I thought, full
of promise. Sunday-school day I was invited to the church
with our children to a good Sunday-school?

Reader, may not you be able to work in the same way?
25 cents Cash paid for Beeswax. 

This is a good time to send in your Beeswax. We are paying 25 cents a pound—Cash—for best yellow, upon its receipt, or 25 cents in trade. Impure wax not taken at any price. Address as follows, very plainly,

Extracted Honey For Sale
ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the great alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can get enough of the alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-loaded basswood blossoms. It has a stronger flavor than alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:
A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of alfalfa, 8 cents per pound; four or more cans, 7½ cents per pound. Basswood Honey, 7½ cent more per pound than alfalfa prices. Cash must accompany order. You can order half of each kind of honey, if you so desire. The cans are boxed. This is all

ABSOLUTELY PURE HONEY
The finest of their kinds produced in this country.

Read Dr. Miller's Testimony on Alfalfa Honey:
I've just sampled the honey you sent, and it's prime. Thank you, I feel that I'm something of a hearse, to sell several thousand pounds of honey of my own production and have buy honey of you for my own use. But however loyal one ought to be to the honey of his own region, there's no denying the fact that for use in any kind of hot drink, where one prefers a more wholesome honey to sugar, the very excellent quality of alfalfa honey I have received from you is better suited than the honeys of more marked flavor, according to my taste.

C. C. MILLER.
McHenry Co., Ill.

Order the Above Honey and then Sell It.
We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

nearly all the drones, and making a hole from 4 to 6 inches square in the center of the bottom-board, with wire-cloth nailed on both sides, then keep cool and travel upward into the sections. If there are many robber-bees prowling around simply make small entrances.

Novocid Co., Mich., Oct. 21, C. CRANE.

Report for the Past Season.
I have 28 colonies at present, I wintered 18. The bees did well the forepart of the season, but it got too dry in July, and has been ever since. I sell my honey for 15 cents a pound, and can sell all I have. I sell to the consumer only. I will have about 1200 pounds this season. I have used 200 pounds of sugar.

Bees on Shares.

Contrary to the advice of some of the sages of bee-culture, a great many people in Colorado are working bees on shares, and getting a start in the business without any great cost to them from their labor. And this chiefly follows from the fact that there are a number of retired apiarists in the State. Yes, these men who have made a competency from the production of honey.

Another class, owners of bees, but unskilled in the arts of rearing queens and marking the practical apiarists, and make a handsome percentage on their investment.

In Colorado at present the share bee-keeping is about as certain to prove remunerative as rain is to fall on the Mojave desert, and when the authorities say that both parties are apt to be disappointed and dissatisfied (especially the owner of the bees), say authorities are apt to be disappointed and dissatisfied. But to reverse irrigated portions of the West, where reverse conditions prevail, things generally go along smoothly, provided the parties have observed the letter and spirit of their agreement.

In taking bees on shares, the Journal, in all cases, advises its readers to have a written contract, covering every feature of the agreement and providing for every probable contingency that may arise. Such a contract should be taken, no matter how honest and good-intentioned the parties may be; the chances for error in the understanding of a frequent trouble will be reduced to a minimum; and, besides, it is business.

The shares given for the use of the bees varies according to conditions. Where a few colonies are picked up here and there and united with another colony, the bee-keeper considers each colony is a fair compensation, if the season is good, and less if it is poor. Where a large number of colonies are united including all necessary fixtures and ground furnished for apiary, the lessee performs all the labor, charges the owner with half the expenses, sections, foundation, shipping-cases and new hives, and at the end of the season the process are divided; that is, each takes share of the honey and one-half of the increase. It is usually stipulated that the share of honey belonging to the bee-keeper should be delivered to him cashed, graded and ready for market.

The Journal will sum up the matter by saying: If you cannot get a start in bees in any other way, take them on shares. But if you can acquire queens by any other means, you must have to pay 15 to 25 percent for it, better do that and buy your bees outright. You would be better off buying your bees outright, after the latter plan.—Rocky Mountain Bee Journal.

An Aid in Setting Foundation.

In placing foundation on the wires in brood or half-depth frames, I find that the imbedding of the hexagonal teeth of the half toothed wheel, used for the purpose, by doing the rolling over a block or board covered with upwards. A piece of paper or a piece of the universe side up, would answer. Is this much better than rolling on a board. I cut a board just enough to fit the inside of a piece of an empty frame, and stretch the burpaul over it, tacking around the edges with two or four ounces twines; nail this board to a piece. After the foundation is secured in the slotted top-bar of the frame, the latter is placed over the frame or block, and the rolling done as usual.—M. F. REEVES, in American Bee-Keeper.

The Colorado Convention, to be held at Denver, Nov. 18, 19 and 20, promises to be one of the very best ever held by that excellent Association. In connection with the interest- ing program, a summary of which appears on page 675, Secretary D. W. Working has since sent us the following, which must prove of special interest to our Colorado readers:

Pro. Gillette will be prepared to measure "long tongues," and show them under the microscope.

PRESSE LIST.

A. Best and most interesting general exhibit—One improved German Steam Wax-Press, large size, offered by the A. L. Root Co.

B. Best case of a hive of bees, the best beehive or hive box, the best honey-comb wheel, used for the purpose, by doing the rolling over a block or board covered with upwards by the A. L. Root Co.

C. Best case of a hive of bees, the best beehive or hive box, the best honey-comb wheel, used for the purpose, by doing the rolling over a block or board covered with upwards by the A. L. Root Co.

D. Best case of a hive of bees, the best beehive or hive box, the best honey-comb wheel, used for the purpose, by doing the rolling over a block or board covered with upwards by the A. L. Root Co.

E. Best case of a hive of bees, the best beehive or hive box, the best honey-comb wheel, used for the purpose, by doing the rolling over a block or board covered with upwards by the A. L. Root Co.
Great Combination Subscription Offers.

Combination and concentration in business are the magic watchwords of the age in which we live. Why should it not be applied to the matter of subscriptions to magazines and periodical literature in general? We believe it is a wise move, especially when it is in the line of economy for the reading public. Now, if we can be the means of saving our subscribers several dollars a year in their reading matter, and at the same time help them to the best literature published to-day, we shall feel that we are doing a good thing, indeed.

We have entered into an arrangement whereby we can furnish the following excellent periodicals at greatly reduced prices:

<table>
<thead>
<tr>
<th>Regular price</th>
<th>THE DOLLAR PAPERS.</th>

three months ago, so that the best honey could have been saved for exhibition. Members are
urged to make the best possible use of the opportunity offered to bring the best honey and
other products typical of our industry, and to prepare their exhibits so that they will
show creditably. The place and time of the meeting will assure as a large attendance of
beekeepefis and others interested in bees and honey. The further effort is made for the
bees, and not for the exhibitors, because of their value. The honor of winning will be worth more than the
premises. It is the beehive and the bees, and the judges of the beehive will have a view with a secure absolute fairness, as
well as ability to judge justly.

D. W. WORKING, Sec.

CONVENTION NOTICES.

CHICAGO.—The executive committee of the Chicago Bee-National has arranged that the next meeting be held all day and
evening, Tuesday, Nov. 30, and Wednesday, Dec. 1. The Bee National will hold its Annual
Exposition in Chicago at that time (Nov. 30 to Dec. 1); begone one fare $2.00 for the
round trip. This notice goes by mail to all beekeepers in Illinois, and should result in the
greatest attendance ever. A special train will take nearly 300 beekeepers near Chicago, and should result in the
largest attendance ever. The writer (D. C. Miller) and Mr. C. F. Daddie have promised to be
present. Let all come.

GEORGE W. YORKE, Pres.

COLORADO.—The Colorado annual meeting promises to be a genuine success. The program
has been made out for a number of weeks, and is almost ready for publication. It has come
to be about what we expected to see at a yearly review of the state, before our Association, and so very few who
do not know of the exciting results of the first meeting. One paper is already in the hands of the
secretary. On two or three nights a big magic lantern show is given by the famous author of bees and the bee industry. And then we are
going to have an evening of the choicest—honey in the United States (made in Colorado,
you know), and wax, with bees enough to show
how the bees live in the wild.

If you want to know more, or have forgotten the
dates, Nov. 30 to Dec. 1, write to the under-
signed, 612 Denver, Colo.

D. W. WORKING, Sec.

MINNESOTA.—The Minnesota Bee Keepers’ As-
semble, under the presidency of Mr. Rev. O. W. Church, 201 14th St. and Nicollet Ave., Minneapolis, Minn.,
Wednesday and Thursday, Dec. 4 and 5, 1903, will be held at the Commercial Club, Minneapolis, Minn.
Joining the National Bees Keeper’s As-
semble, and having a meeting on Wednesday, Dec. 8, All bee keepers and those interested in bees are invited.

H. G. AKELIN,
Chairman Executive Committee.

ILLINOIS.—The Illinois Bee Keepers’ As-
semble will hold its 11th annual meeting on
Nov. 19, and 20, 1901, in room 17, at the State Il-
inois Hotel, Springfield. We have arranged that there will be a
program we expect every one to come prepared to take advantage of those asked by others. Those who attend our meeting can
arrive themselves of the Odd Fellows’ rates on the trains. The Central Passenger
Association has made an open rate of one
fare for the round trip. Other roads in the Central Passenger Association will at least
give a rate on a fare and a third for the round trip. We hope that it will be as low as this
one-fare rate. There is no better way for beekeepefis to have a place at a larger rate
than themselves of the cheap railroad rates, and terms will be given to those who ask if we
rest a discussion on some particular topic, just
write a short paper on same, and rest assured the discussion will be held.

J. A. STONE, Sec.

R. R. No. 4, Springfield, Ill.

THE MAGAZINE AGE.—Never since print-
ing began has periodical literature been so
rich, varied and attractive as at present. A
laudable effort has been made to bring the
people of our country to a pitch of excellence, while unusual activity, ingenu-
ity and enthusiasm are being utilized for circula-
tion from city to cross-land the country over.
Keen competition has also brought the price of
books and papers on a point so low as to touch the pocket lightly. All this has re-
sulted in making us a nation of magazine readers in a remarkable manner. The
former have increased in a single magazine and counted it a luxury, fifty now look upon it as a necessity.

Preuss BEE-KEEPER.
AMERICAN BEE JOURNAL

Nov. 14, 1901.

We have a Large Stock on hand and can ship promptly.

SEND US YOUR ORDERS FOR
HIVES, EXTRACTORS

OR ANYTHING YOU WANT IN THE BEE-KEEPING LINE.

WE MAKE ONLY THE BEST.

Our Falcon Sections and New Process Foundation are ahead of everything, and cost no more than other makes. New Catalog and copy of THE AMERICAN BEE-KEEPER free. Address:

THE W. T. FALCONER MFG. CO.,
JAMESTOWN, N.Y.

$5 W. M. Gershish, East Nottingham, N. H., carries a full line of our goods, at catalog prices. Order of him and save freight.

Please mention Bee Journal when writing.

Queen-Clipping Device Free....

The MONETTA Queen-Clipping Device is a fine thing for use in catching and clipping Queens wings. We sell it for 25 cents; or will send it FREE as a premium for sending us ONE NEW subscriber to the Bee Journal for a year at $1.00, or for $1.00 we will mail the Bee Journal one year and the Clipping Device. Address,

GEORGE W. YORK & COMPANY,
Chicago, Ill.

BEE-SUPPLIES!

ROOT'S GOODS AT ROOT'S PRICE.

Everything used by bee-keepers.
POUNDER'S HONEY-JARS. Prompt service. Low Freight Rates. NEW CATALOG FREE.

WALTER S. POUNDER

A New Bee-keeper's Song—

"Buckwheat Cakes and Honey"

Words by EUGENE SECOR.
Music by GEORGE W. YORK.

This song was written specially for the Buffalo convention, and was sung there. It is written for organ or piano, as have been all the songs written for bee-keepers. Every home should have a copy of it, as well as a copy of "THE HUM OF THE BEES in the APPLE-TREE BLOOM" written by EUGENE SECOR and Dr. C. C. MILLER.

Prices—Either song will be mailed for 10 cents (stamps or silver), or both for only 15 cents. Or, for $1.00 strictly in advance payment of a year's subscription to the American Bee Journal, we will mail both of these songs free, if asked for.

GEORGE W. YORK & Co.
144 & 146 Erie St.

24th Year Dadant's Foundation. 24th Year

We guarantee satisfaction. ** Why does it sell so well? **

What more can anybody do? BEAUTY, PURITY, FIRMNESS, NO SAVING, NO LOSS.

PATENT WEED-PROCESS SHEETING.

Send name for our Catalog, Samples of Foundation and Veil Material. We sell the best Veils, cotton or silk.

BEE-KEEPERS' SUPPLIES OF ALL KINDS.

Very fine pure-bred BARRED PLYMOUTH ROCK Chickens and Eggs for sale at very low prices.

Langstroth on the Honey-Bee—Revised,
The classic in Bee-Culture—Price, $1.25, by mail.

Beeswax wanted at all times.

CHAS. DADANT & SON, Hamilton, Hancock Co., Ill.

Please mention Bee Journal when writing.

Texas Bee-Keepers.

New Branch Office. We beg to announce the opening of a branch office and warehouse at 45 W. Houston St., San Antonio, Texas. Rates of transportation from Medina in less than car-load lots are high, and it takes a long time for local shipment to reach Southern Texas points.

Low Freight and Quick Delivery.

San Antonio as a Shipping-point.

To secure these two necessary advantages—low freight and quick delivery—and to better prepared to serve the interests of our Texas friends is our reason for establishing this new branch office. No other point in Southern Texas is better adapted to serve as a distributing point than San Antonio. It has four great railroads—the Southern Pacific R. R. and West—the International and Great Northern R. R. from Laredo up through San Antonio and Central Texas; the San Antonio and Arkansas Pass R. R.; and San Antonio and Gulf R. R. It also has the American, Wellis-Fargo and Pacific Express Companies.

Our Managers.

We have secured as managers Mr. Udo Tooperwein, formerly of Leon Springs, and Mr. A. W. Walton Jr., both of whom are well known to the bee-keepers of South and Central Texas. They are also thoroughly familiar with practical bee-keeping and all matters associated with it, and any orders sent to this branch will receive prompt, careful attention.

Our Goods.

As usual our motto is to furnish the best goods of the most approved pattern. We do not undertake to compete in price with all manufacturers. Bee-keepers have learned that it does not pay to buy cheap supplies, for a saving of 10 cents on the first cost of a hive may be a loss of many times this amount by getting poorly made and ill-fitting material. Every year brings us many proofs that our policy of "the best goods" is a correct one.

Our Catalog. Very few changes in prices will be made in our new catalog, so do not delay your order, but send it at once. You will be allowed a refund if lower prices are made, and in case of higher prices ruling in the new catalog, if any, you will receive the benefit by ordering now. Catalog and estimates may be had by applying to the address given below.

Our Invitation. Whenever you visit San Antonio you are invited to call at our office and make it your headquarters. Here you will find a display of Apisarian Supplies not equalled elsewhere in Texas. You will also find on file the leading bee-journals to pass pleasantly your leisure time.

Spanish Catalog. Some of you may read Spanish, or have a bee-keeping friend who does. If so, call for our Spanish catalog. It's sent free.

FACTORY AND HOME OFFICE:
THE A. I. ROOT CO., Medina, Ohio.

BRANCH OFFICE:
THE A. I. ROOT CO., San Antonio, Texas,
438 West Houston Street,
TOOPEPERWEIN & WALTON, Managers.

GEORGE W. YORK & CO., 144 & 146 Erie St., CHICAGO, ILL., are headquarters for ROOT'S BEE-KEEPERS' SUPPLIES IN CHICAGO. Send to them for their free Catalog.
MISS EMMA WILSON—DR. MILLER'S SISTER-IN-LAW
AND CHIEF HELPER IN THE APIARY.
The "Barler Ideal" OIL-HEATER ....

Saves its Cost Every Year!
No Odor! No Smoke! No Ashes!

Costs only a cent an hour to run it.

The editor of the American Bee Journal is using the "Barler Ideal" Oil Heater, and it is all right in every way. We liked it so well that we wanted our readers to have it too, so we have recently arranged with its manufacturer to fill our orders. The picture shown herewith is the one we have. It is a perfect gem of a stove for heating dining-rooms, bed-rooms, and bath-rooms. It hinges back in a substantial way, and is thoroughly well made through. The arra removes for heating water. The brass fount, or wall, has a bail, and holds nearly one gallon of kerosene oil. It is just as safe as an ordinary lamp. You wouldn't be without it for twice its cost, after once having one of these stoves. Most oil-stoves emit an offensive odor, but this one doesn't. Its height is 8 ½ feet, and weighs 50 pounds, or 90 pounds crated ready for shipment, either by freight or express.

Price, f.o.b. Chicago, $6.00; or, combined with a year's subscription to the American Bee Journal—both for only $6.50. FULL DIRECTIONS GO WITH EACH UNIT.

If you want something that is really serviceable, reliable, and thoroughly comfortable, you should get this "Barler Ideal" Oil Stove, as it can easily be carried by any woman from one room to another, and thus have all the heat you want right where you want it.

Please Mention the Bee Journal when writing Advertisers ....

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

H. HOWARD M. MELBEE, HONEYVILLE, O. 

(This Cut is the Full Size of the Knife.)

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver. The linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it, otherwise to try to destroy the name and address, would destroy the knife. It traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your Pocket-Knife will serve as an identifier; and in case of death, your relatives will at once be informed of the fact.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side? 

The accompanying cut gives a faint idea, but, cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to appreciate the name and address, and its beauty.

How to Get this Valuable Knife.—We send it postpaid for $1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with $3.00). We will club the Novelty Knife and the Bee Journal for one year, both for $1.90.

GEORGE W. YORK & CO.,
St., Chicago, Ill.
A Dr. Miller Number is what might be called this week's issue of the American Bee Journal. When we visited him recently we discovered the original photographs of the pictures shown, and decided to use them in a single number, as we now have done.

As we have described quite fully each illustration, no extended write up by us will be necessary. Still, if there is anything about the pictures our readers would like to know more of, they can easily send in their proper questions to Dr. Miller, when he will reply to them in these columns.

We wanted very much to show a picture of Mrs. Miller, but she said "No" in such a kind, yet decided, way that we felt we must respect her wish. She is a most lovely woman, greatly interested in all the Doctor's work and writings. Of course, you'd expect Dr. Miller to have just such a wife.

As our readers know, Dr. Miller is past his 70th birthday, and yet no one would suspect him of being nearly that age. He retains his youth in a wonderful manner. But that comes from the spirit that dwells within, and that shines forth in his daily life. It keeps him young and happy. May it also keep him with us yet many years, to bless and to cheer all who are so fortunate as to meet him or his helpful words.

The 3rd International Congress is to be held Sept. 9, 10 and 11, 1902, at Bois-le-Duc, Holland, and the program is already published. Among other topics are: The role of bees in fertilizing grain and grape-vines; increase of bee-pasturage; causes of swarming; influence of food upon the brood; length of bees' tongues; foul brood legislation in different countries; adulteration of honey and wax; suppression of fumigation of bees sent from one country to another. The last topic is to be in the hands of our esteemed countryman, Mr. Dadant.

Sampling Honey in the best way is a matter of considerable importance. At fairs or other exhibitions it is important that nothing untidy shall be done, and it is by no means a pleasant thing to have a spoon passed from one person to another or dipped into honey after having been in the mouth. The matter is perhaps more strongly accentuated in the case of selling honey by samples, for a prospective customer, on being handed a sample of honey in a spoon, has no means of knowing who the preceding taster has been, and in some cases he will plumply say he wants no honey rather than to put in his mouth that which may previously have been in a mouth that was filthy or diseased. The best way to have no suggestion of uncleanness is to avoid the use of anything the second time—in other words, to throw away immediately whatever has been used once.

A common wooden toothpick serves a fair purpose, and for sampling comb honey there may be nothing better, for with a toothpick there is no need to break open more than one cell. For extracted honey something a little broader than a toothpick would be better. Some have spindles specially prepared, and it might be interesting to learn from those of experience what is the best and most convenient thing.

Spraying Fruit-Trees in Bloom.—An editorial in the Farmers' Review, after speaking of the harm to bees, says:

It has also been discovered that the poison is equally destructive to the life of the pollen, even when the amount of poison is only 0.5 or 10 parts in 10,000. Even two parts in 10,000 has been frequently found fatal to the pollen. The danger to the pollen is, however, greatly lessened by the fact that the blossoms do not all open at once, but the process extends over several days. In a clump of five blossoms the central one opens first, and spraying at that time kills the pollen in only these open blossoms.

Crate, Rack, or Super.—Something of a controversy is now on in the British Bee Journal as to the proper term to use for the receptacles on the hives that hold sections. The supply catalogues and some of the correspondents have it "crate," while the journal insists it should be "rack." They might do worse than to compromise by using the word in almost universal use in this country—"super." Unfortunately, while there is unanimity in this country as to the written word, the spoken word is by no means always the same. It is just as much out of the way to say "super" in place of "super" as it would be to say "eœur" in place of "eœur."

Moving Bees.—The distance bees can safely be moved—that is, without danger of their returning to the old location unless special precautions are taken—is a matter that depends upon circumstances. It may be two feet, or it may be two miles, much depending upon the time of year. After bees stop flying in the fall, and up to the time when they begin to gather in the spring, they may be moved any number of inches or feet, and there will be little danger of any return-
placed for the bees Sept. 25, but were left untouched the entire day. Next day the clusters of grapes were sprinkled with honey-water. They were vigorously attacked by the bees, the sweetened water licked up clean, yet not a berry injured. September 29 the clusters were changed, sprinkled with honey-water, and five berries in each cluster pierced with a needle. They were promptly licked off, the punctured berries emptied, and the rest left whole. The beemasters did not question being punc-
tured in each cluster, and these alone cleaned out, except two or three berries that had probably been accidentally injured. Black Portuguese grapes were an exception; ripen-
ing early they burst open, especially in wet weather, and, of course, were then cleaned out by the bees.

A Good Word for the Blacks is spoken in the Rocky Mountain Bee Journal, A. E. Willett has blacks with a tongue-reach of 16-100 inch which gather more than his Italians with 10-100, and he thinks if blacks had had as fair a chance as Italians the blacks would be ahead.

Weekly Budget.

That Texas Horsemint paragraph, on page 706, was written by Mr. Louis Scholl, instead of Editor Root. The wrong credit is clearly an error on our part, as we have since noticed that it is plainly stated in the original article from which the paragraph was taken, that Mr. Scholl was requested to write about the horsemint, after Mr. Root had departed from Texas. We are glad to make this correction.

Mr. W. Z. Hutchinson, writing us Nov. 10, said:

FRIEND YORK,—When at Buffalo I prom-
ised Mr. W. G. Aclln that I would come up to their December convention at Minneapolis, Minn. I have just received notice that it will be held December 14th and 15th. This throws me out of attending the Chicago convention. I am sorry, as I had anticipated having an enjoyable time.

Yours truly,

W. Z. Hutchinson.

Well, that is too bad. But the meeting will be a good one, anyway. Of course, all would like to have Mr. Hutchinson present, but what will be our loss will be Minnesota's gain.

Mr. W. J. Chalf, the editor of the Cana-
dian Bee Journal, and with a very pleasant gentleman, was present at the Buffalo con-
vention, and has this to say editorially:

As was previously announced, the exercises consisted principally of questions and an-
swers. We were afraid at first that this kind of manner would become monotonous and tiresome, but the interest continued right through, and very much valuable information was imparted. Mr. E. R. Root, proved him-
self an ideal chairman, and perfect order and good humor prevailed during the sessions.

Dr. A. B. Mason, the genial secretary, has a happy faculty of making people feel at home. We Canadians were treated with the greatest possible courtesy and consideration; pleased to say we had a good representation.

The Buffalo Convention.

The Report of the Proceedings of the Thirty-Second Annual Convention of the National Bee-keepers' Asso-
ciation, held at Buffalo, New York, Sept. 10, 11 and 12, 1901.

(Continued from page 727.)

USING FOUNDATION FOR COMB HONEY.

"Is it desirable to use drawn foundation in securing comb honey?"

Mr. Wilcox—Some years ago I was called upon to conduct some experiments on the subject of the use of full sheets of foundation and small starters, and, from those experiments, I might say that the result showed that the most expedient way, when they were filled and finished, hence the drawn comb was the first filled and finished, the full sheets of foundation next, and the small starters last. This suggests probably relates to the prac-
tice of putting in a sheet of foundation to be drawn out half length or more, to be cut up and used in sections as starters for the bees. I am satisfied with that experiment and subsequent experience, that the bees produced more honey if supplied with combs fully drawn out. At the same time, I do not think it practicable for the majority of bee-keepers to do it. The difficulty or trouble of getting them drawn out balances the gain, I believe, in the use of the small.

Mr. Heise—I think probably Mr. Wilcox has the key to the question. I thought probably this referred to the artificially drawn combs. Probably it does not.

Mr. Betsinger—I hate awfully to let it stand in that form. My experience is that they will use foundation, do better work and fill the section quicker than they will with the foundation that has been drawn out previously, especially if it has been carried over one season.

FLAVOR OF RED CLOVER HONEY.

"Can any one tell me the flavor of red clover honey?"

J. J. Moore, of Ohio—We have had a good deal of red clover, which is of course the thing we have never experienced before, and generally after the middle of July the bees seemed to settle back and think they have done all that is neces-
sary, but this summer they have gath-
ered considerable honey from red clover. It is very much like white clover. When you open a hive in which it has been gathered freshly it reminds you of white clover. It seemed to be very white and nice. The bees were at work on red clover and there wasn't anything else to gather. It is in Seneca County, Ohio. Some of the bees were pure Italian; most of them were hybrids. Hybrids are kept more easily than Italians in our section. There was white clover early in the season, but later there was very little of it. Mr. McEvoy—Every kind of bee has gathered honey this year from red clover.

Dr. Mason—I suppose there are a lot of many of those present who have robbed humble-bees' nests, and if you have, and tasted the honey, you know just how red clover honey tastes. It has a real, nice flavor.

Mr. Hershiser—Referring to the secret-
ary's remark about humble-bee gathering red clover honey, I would like to know if humble-bees do not take other honey than red clover honey.

Dr. Mason—I think the flavor of red clover predominates. I have tasted of it quite a good many times in different apiaries, and the parties have called my attention to it as having been gathered from red clover.

HONEY FERMENTING IN THE COMB.

"Will honey ferment in the comb?"

Mr. Wilcox—I know it will.

Mr. McEvoy—Yes.

Mr. Mason—That depends on where it is kept. I believe.

Mr. Wilcox—Whenever it is kept warm enough to absorb moisture, and once the moisture clings to the honey, and if it is continued warm and moist, it will ferment. If it is kept warm and dry it is all right. It must absorb the moisture first to ferment.

COMBS OF CANDIED HONEY.

"What is the best method of handling combs that contain candied honey, in the spring?"

Dr. Mason—Uncap it and give it to strong colonies.

Mr. Moore—I would advise uncapping it and pouring water on the comb where it is candied. Bees will use it up.

Dr. Mason—if the honey is kept you need not pour any water on it. If it is dry, pour on some water.

W. L. Coggsall—I would just pile the combs up with the candied combs outdoors where the bees could have access to them, and that honey you can take and put in a wax-extractor and liquefy it.

Dr. Mason—if it is moist, you would not need to do that way.

W. L. Coggsall—I wouldn't pour any water on the combs.

"WHAT IS A TESTED QUEEN?"

Mr. Wilcox—One you have tried and found to be good for nothing.

Mr. Heise—is that the only way we can tell tested queens?

Dr. Mason—The other is when it has been tried and found to be good.

Mr. Beaton—I think some one who has asked that question would like to know what a tested queen is. In pop-
ular parlance a tested queen is one that has been kept until we have seen
her worker-bees and know from their markigns that they belong to the race then it is proper for them to belong to. A queen is partially tested as soon as you have seen her deposition of eggs, when you have observed that she has deposited eggs and laid them regularly; but in Mr. Benton's case, it is a queen whose workers you have seen and which come up to the standard of the race she is supposed to belong to. You can possibly get somewhat farther and test her for her queen progeny, test her for their gathering qualities; but I think everybody understands the popular method.

Mr. McEvoy—I like a queen to lay her eggs so that when they come to cap the cells they will all be capped in one day. I do not like an irregular layer.

Mr. Benton—I want the brood to be in solid. It develops better because of its mutual heat. The developing insect develops a great deal of heat, and we can test a queen from the appearance of her eggs.

Mr. Moore—I have an idea that the man who would dream a bee's last motion would like to know if he has an Italian queen. How would you know the progeny? What is the marking of an Italian queen?

Mr. Benton—The first and prime point is three yellow bands on the anterior part of the abdomen, that is, directly under the wings or near the throat of the bee. In the light, because there are dark and light Italians, and I should say that the queen that gave workers showing those things is nearer the general large form of the Italian. Whatever brownish tint over the body that is due to the fuzz on the body, would come up to the standard of an Italian queen, and as near as I know that marking is the better it would be in that particular respect. An evenness in the points, every worker like every other.

A Member—I would like to ask Mr. Benton if he could dream a bee an Italian that showed four bands?

Mr. Benton—I would say that was a queen that had been produced by selection, but I would not require that the worker had four bands in order to come up to the Italian standard.

A Member—Suppose most of the bees had four bands, but once in a while you saw one with only three, would that be against her?

Mr. Benton—Decidedly. I would not call that a pure Italian bee.

Mr. Wilcox—I agree with Mr. Benton, that uniformity of markings is the most important point.

MISCELLANEOUS MATTERS.

The secretary then read a letter inviting the members of the National Bee-Keepers' Association to attend to the annual meeting of the Ontario Bee-Keepers' Association, to be held at Woodstock, Ont., in December.

Mr. Heise warmly seconded the invitation.

Mr. York—I would move that we as an association accept the invitation so courteously tendered by our friends from across the border, and as many as wish be bound for that meeting.

The motion was seconded by Dr. Mason and carried.

Mr. York—It seems to me it would be well to have a committee on resolutions to report at the close of the session.

The motion, Messrs. Abbott, C. C. Miller and N. D. West were appointed.

Mr. Benton—I move that the convention adjourn tomorrow at 1 o'clock and meet at the Epworth Hotel in the evening.

The motion was seconded.

Dr. Mason—I move as a substitute that those who wish to go to the Pan-American can do so, and the others retain here.

After a brief discussion the substitute was carried.

Mr. Young—I move that the matter of selecting a badge be referred to the Board of Directors.

The motion was seconded by Dr. Mason and carried.

Mr. Young—On the matter of score card, I would move that the same committee that acted last year be re-appointed to act this year. I think Mr. N. E. France, of Wisconsin, was chairman of that committee. Mr. Hutchinson was also a member, and Mr. Hershiser.

The motion was seconded.

Dr. Mason—if I remember correctly, the score card committee last year made a recommendation and it was adopted by the Association.

Mr. York—I move that the convention select a committee of five to report on the score card before we adjourn, as recommended last year.

The motion was seconded by Dr. Mason and carried.

Mr. York—I nominate Mr. Benton.

Mr. Wilcox—I nominate F. Greiner.

A Member—I nominate Mr. Miller, of Canada.

The score card is a card recommended to be used by judges at honey exhibits.

Mr. Hershiser—I nominate Mr. Hutchinson.

Mr. Heim—I nominate Mr. Hershiser.

Mr. Benton—I would prefer to withdraw in favor of somebody else.

A Member—Then I would nominate W. F. Marks, of New York.

The motion was put and carried.

It was moved, seconded and carried that the roll of those present be called by States. The result was as follows: Massachusetts 2; New York 42; Pennsylvania 8; Maine 7; Vermont 1; Virginia 2; Cuba 1; Texas 2; Missouri 2; Iowa 1; Minnesota 3; Wisconsin 1; Illinois 4; Indiana 1; Michigan 4; Ohio 8; Canada 18; Maryland 1; Connecticut 1; New Hampshire 1; Jamaica 1.

QUESTION ON QUEEN-REARING.

"How many days after the egg hatches will the queen cease to live on the royal jelly, and what does she then live on?"

Mr. Benton—It varies from 5½ to 6 days; in other words, she lives on this royal jelly from her first larval period to the end of her whole larval period; the cell is then sealed over, and she then lives on the fatty tissues derived from the food she ate in the larval condition. The tip of the abdomen, or nymph, is inserted in the food which remains there. I express the opinion that by absorption she does not take from this food anything in addition, but for the greater part I should suppose that she lives from the food deposits or tissue derived from that food. At the end of the larval period the pupa of many insects remain over winter—large numbers—and some insects remain two or three years in this condition before they come out. We have the 17-year locust that remains 17 years in this condition, living on the absorbed tissue.

Mr. Bettsinger—A similar question was discussed within the last two years, and I asked the question how the queen took this food, and of course I renew that membership by the time Dr. Mason gave: but I see he has added that she takes the balance of the food through the abdomen.

Mr. Sleeper—I think I have seen indications that this substance called royal jelly is largely absorbed by the posterior portion of the abdomen during this time after the larva is sealed.

Mr. Benton—I am not in a position to say that I expressed an opinion merely; I have a little basis for that opinion. I have noticed that if cells have been taken at a very early period, this juncture of the pupa in the queen-cell is broken, and she drops to the bottom; of the cell and may never emerge after that—it depends upon the state of development if she emerges; and if she emerges, she may be somewhat inferior through having dropped down. My inference was that she was deprived of the initial part of her development.

Dr. Mason—I think I have seen cases of that kind where the queen was detached in that way in an early period of the development. It injured the queen very materially.

Mr. Benton—The idea would then be not to handle queens roughly, or to move them as little as possible until the perfect queen has emerged.

MEMBERSHIP QUERY.

"If I fail to renew my membership and renew it after, when does the renewal date from?"

Dr. Mason—The renewal dates from the time you renew. If you are a member of the Association and you fail to renew it before the time the year expires, you cease to be a member; so, those of you who are members, don't entertain the idea that you can have the protection of the Association and pay at the end of the calendar year.

DOES COMB COLOR AFFECT COLOR OF EXTRACTED HONEY?

"Does the color of comb make any difference in the color of extracted honey?"

Mr. McEvoy—Take old combs and sprinkle them well with water, shake them, and see if you don't get something a little the color of tea. Take a very young comb, and see what you get from that. Now, after a comb has been used several times and extracted, the bees have cleaned it out so much that you cannot get anything from it.

Mr. Bettsinger—I made it a business to attend a good many fairs and I have seen some pretty fine honey; I have made a great point to find out where it came from, and I believe there is an exhibition today in our State, and the
extracted honey was taken from old combs. There was also honey there taken from new combs. It has not taken the first premium because of its lack of color. Now, I will admit that you must have brownish or yellowish combs and get color from them, but it is not honey. Honey doesn’t take on color. You can lay it down in the dirt and it will still be white.

Mr. Wilcox—I would like to ask you if your first extracting is not a little darker in color than the next honey-

Mr. Betsinger—I would say, no, sir. The honey taken the second time is no whiter than the first, but the season in this State is not long enough to get honey. The honey has been on the combs so long that I would have to extract every day to get the same quality; our flowers vary from day to day.

Mr. McEvoy—I have been 18 years an inspector in the Province of Ontario, and I think very few men have more thoroughly tested the quality of old and new combs, and my experience has been that old combs do not have a shade of color. You will get, perhaps, a little better color of honey from one colony than another.

Mr. Betsinger—I don’t mean to say that one colony gets whiter honey than the other from the same field?

Mr. McEvoy—I would not say the same.

Mr. Davidson—I would like to add my experience to that of Mr. McEvoy. I have been in the extracted-honey business a good deal, and while I have not always taken color, I do know that honey taken at the same time stored in light and dark combs will have different colors. I have tested it in our extracting in Texas. The bees store the honey in the brood-combs sometimes, and I have to separate those combs and keep them separate from my regular extracting-combs in order to keep from coloring the whole lot of honey. I know it is gathered at the same time and by the same colony.

“Journal”—My opinion is that the comb has a lot to do with the color of the honey, because down our way all our honey is pure white. I have known the bees to extract honey in dark or old combs and it brings out a dark honey with a very inferior flavor.

A Member—It occurs to me that perhaps there may be a double meaning. Mr. Betsinger may refer to old combs that have been used a number of years for extracting, and some one else may refer to combs that have been used in the honey business, and put into the hive and honey extracted from them. In that case my experience would be that the honey is somewhat colored.

W. L. Coggshall—Mr. Davidson, in talking of that matter, said he got more or less bee-bread in the honey, which made it a little bit colored. Mine is almost colorless, but honey, and, of course, you couldn’t see much difference there. I think there is hardly enough difference to make it worth while to take care of.

Dr. Mason—This is an important matter. Some of you produce dark honey only, and that is all, and your opinion isn’t worth much. It is only a few years since, that I advocated this matter that it did color, and I was laughed at; and no longer ago than two years, in the Philadelphia convention, when I spoke of this, President Whitcomb said, “Do you believe that honey dissolves the wax?” Mrs. Harrison recently said something on this subject. Mr. Betsinger has a lot of bees—“when you want nice, light honey get nice, new combs.” Now, I have had a good deal of experience in this line, and this year I have been fully convinced of it than ever. I have combs that had been used as brood-combs for years, and that had not been used as such for the last two years. I am just about to put them in supers with combs that were never used for brood-rearing; I uncapped the old and the new and extracted, the old combs in one extractor and the new combs in another. I put them in supers with combs that were never used for brood-rearing; I uncapped the old and the new and extracted, the old combs in one extractor — and the co or was so different that you wouldn’t believe it was the same honey. Now, I am so thoroughly convinced of this that, although I have about six full extracting combs to the colony, I am going to destroy every one of them and put new ones in place of them, and I shall have honey not colored by old combs.

Mr. Betsinger—I may be behind the times, but I am not behind in long years of experience. I have extracted, and I am convinced of course, that old and new combs, and I would not give a snap of my finger for the difference between old and new combs.

Mr. McEvoy—I couldn’t be under- stood as saying that using old combs is going to give you a dark-colored honey. I would use it several times before I would think it sufficiently washed out.

Mr. Terrell—I wish to endorse what Mr. McEvoy has said. The question is whether it refers to old combs that have been used for years for extracted honey. This season I have taken combs from old colonies, placed them on top for extracting purposes, and the first honey extracted was decidedly colored, but as I kept on taking off the honey, the last extracting there was not very much difference between the honey from the old combs and the new ones.

Mr. Benton—When the honey is first gathered it is about three-quarters water. Now, if pure water would take away all the color in the honey, I have said, Mr. Mason—I have used a lot of dark quarters water and one-quarter sugar!

W. L. Coggshall—In sending some bees down to Cuba I sent along some combs, and I left from 10 to 12 pounds of honey in each colony, and it took them that whole season down to get that dark honey out of the colonies. The bees kept carrying it up, and it took longer to get the dark honey out of the hives.

F. J. Miller—If there is any person who is doubtful about this, if he will just send me a sample of honey to show how it will stand half an hour and then pour it out, he will see a decided black color; and if he refills that comb the color will gradually grow lighter. Dr. Mason is right in saying that I could not make an exhibition article of honey from those brood-combs. Commercially speaking, it would not matter, but it is probably the right thing if you were doing it for exhibition purposes it would make a decided score against you.

Mr. Wilcox—All the arguments go to show that the first extracting is darker colored than the second, but they don’t show why, because that color comes from the comb itself, or the accumula-
tion of dust and dirt that may be in that comb during the winter season. I have supposed that it was an accumulation of smoke or dirt which might have gotten into the combs during the winter. I don’t know whether that coloring is in the comb itself. I shall be slow to destroy my old black combs. I shall keep them and extract from them.

Mr. Betsinger—The gentlemen mention their first extracting as being a little colored. Honey isn’t water; it is an extract. You cannot make a wash with honey.

Mr. McEvoy—Allow me to explain a little. A member speaks about the first extracting of honey. Now, honey no honey excepted clover, and the clover from the white combs is a shade whiter on the start than it is from the old combs.

Mr. Betsinger—if you were in a locality where you didn’t have one drop of honey in the brood-chamber—none at all—no colony coming to maturity—then I must say you are a happy man to extract honey.

Mr. McEvoy—I uncrap between fruit, plum and clover, and I convert the honey. I see it differently. I think of course, that the honey is as the system I follow, and Mr. Miller knows it. I think that I can prove my case.

Mr. Betsinger—Does any mustard grow in that locality?

Mr. McEvoy—I dare say you could find some, but I myself don’t know where it is.

Mr. Stevens, of New York—Is the honey stored in those dark combs affected any in flavor by storing in them?

Dr. Mason—No, sir; it takes a fine taste to tell it. No man who chews tobacco can tell the difference.

SMOKING BEES WITH TOBACCO.

“Is it detrimental to the bees to use tobacco-smoke whenever necessary to open their eyes?”

Mr. McEvoy—I don’t think it is necessary ever to use tobacco-smoke.

Mr. Benton—I would say, decidedly, never use tobacco-smoke on the bees. I have had a lot of bees with which I don’t think of using smoke or veil. I take out the combs and shake the bees off without ever getting a sting.

Mr. Benton—I think there are times when some have claimed that tobacco-smoke was useful in introducing queens, but I should think that being strong-scented and producing a strong odor in the hive would probably convey to the receiving of a queen, and I do not think it is properly introduced, not to use tobacco-smoke on queens.

Mr. Moore—Does tobacco-smoke have a more detrimental effect in conquering very cross bees than just ordinary smoke?

Mr. Benton—I think if used on the ordinary cross Italian bee it is a good thing, but not on Cyprians.

Dr. Mason—I have sometimes tried it in introducing queens, and it has seemed to be a help.

Mr. Hershiser—I tried uniting colonies of bees, or nuclei, to make the colonies strong enough to winter, some years ago, and gave them so much that it made them sick, so that they dropped down to the bottom of the hive, but after they “came to,” again they
Queen-Breeding and Improvement in Bees.

BY A. NORTON.

There is no matter for rejoicing that so much attention is now being given to the improvement of stock in the apiary. In one sense the movement is not new. For years individuals have worked along this line and have done what they could independently, some in one direction and some in another. But the movement has not become systematic; it has grown so much in magnitude and is attaining so many of our most systematic apiarists and queen-breeders that we may expect to see it assume more and more systematic shape each season. The results do not prove too temporary to warrant its continuance. At least the united efforts of breeders will demonstrate how much dependence may be placed upon this hope of improving our races of bees, so that more intelligent estimates may be formed in the near future than at present. Even yet there is room for betterment in the aims of our improvers, some of whom decry what others are bringing about, and narrow their desires down to certain points, to the exclusion of other desirable ones. But we may hope that broader and so more uniform aims may be realized and that all breeders will be pursuing the same parallel paths.

Through but few pages of earth's record can we trace back bees and breeding. Geologically we know bees of sundry species as early as the Eocene epoch (or Mammalian time). The oldest known specimens are found preserved in the Eocene amber, or fossilized wax, on the shores of the Baltic Sea. That was about the time of the first appearance of flowering plants and trees, and before there was any one to domesticate and breed them. There were none even to love the sweetness of their garnerings till the cave bear came, unless animals of some other then existing orders were fond of honey.

How long honey-bees have been the associates of man as domesticated insects can not be ever conjectured. Historically, the searches into this question that we have seen from time to time in the American Bee Journal have carried as well into antiquity, but have not brought us to any answer. They have shown, however, that anything like intelligent handling and careful breeding is by no means ancient, and that our present improvements have been accomplished within a short period. While we should avoid over-conservativeness, or "old fashionedness," in regard to progress, we may, on the other hand, get into over-enthusiasm in our visionary hopes.

In considering the subject of breeding bees, and the possibilities that lie therein, men are liable to let preconceived ideas carry their hopes, if not beyond the possible, at least beyond the probable. Yet the experiments and expectations of what breeding may bring forth, are likely more wrong in their premises than in their conclusions. If the theories we are just now told we must believe or be behind the times, are true, the tide evolved from dead matter and man originated in some monkey, and so on back in formless protoplasm, why need we limit our ambition in the line of breeding? Let us produce Apis dorsata, or something just as good, from the bees we already have, instead of searching Asiatic jungles for them. Let us breed bees from wasps, or perhaps develop mosquitoes into storers of nectar instead of probers for blood.

Domestication hastens variation and increases it; but the balance of variation and heredity will always continue stable. Natural selection, therefore, may be considered as God's preventive of degeneracy, and not a substitute for creation; and, as surely as God circumseribed the ocean, He has also set the bounds of propagating organisms—"So far shalt thou change, and no further." Logic may lead us astray in these matters. If we reach the North Pole and keep on traveling, we will be getting away from it. So it is with truth, which is the only science: for logic, assumption, and speculation are not science.

"Take, for instance, the familiar illustration of the deer and the wolves. The fastest deer can save their lives and breed faster offspring; and thus their speed has been attained, say logic, assumption and speculation. This necessitates the assumption that they once were slow. Do we know this to be a fact? How did they become slow if not by a process of evolu-
course this was all since the time when flowers had no nectar at all, and bees had no use for honey, but made their living in some entirely different way. However, we must sadly admit that no assumption and logic based on natural selection can satisfactorily explain the uniformity of color in worker-bees, especially when we consider how variable in this respect are both queens and drones—the progenitors—and how shockingly they disregard all color-lines in mating; also, how little they could tell (if they wanted to know) what complexities their children would have, from the looks of each other.

But coming more directly to the subject of breeding bees, we really face the fact—which in proportion as it is known constitutes so much true science—that by careful selection we may induce changes in our bees in various directions until we reach the limit which the Creator has established: but beyond that we can go no further. The evolution of the yachting has shown continual increase of speed for many years. But the fact that this year’s "Constitution" couldn’t outsail last year’s "Columbia" awakens us to the realization of what we should have already known, that the speed of sailing-vessels can not increase forever. A swifter yacht than "Columbia" might yet be built; but some vessel must some time be built than which none can be made any swifter. And so with bees, or poultry, or anything else domesticated. But we should strive to improve as far as improvement can be made. If we take care of the improvements, the limits will take care of themselves.

The writer does not assume to tell eminent and successful queen-specialists what they should do to better their strains; he will be content if he brings out any established truth that they may have overlooked, or the "laity" have forgotten, is a mistake to assume that development can be carried on in only one direction at a time. Our Italian bees may be made (and they have been made) better in more respects than one. To take any one example among domestic animals: the Hou- dan fowl was in some period bred into one having a large, shapely crest and muff, a peculiar comb, regular characteristics of color, good size, great prolificness in egg-laying, and small amount of offal, and with the sitting instinct about entirely bred out. And with all this the fowl is hardy and strong. Now all these make a great many features to work for in the same breed, and the result was surely achieved. And we can find the same to be true of too many varieties of fowls, cattle, etc., to be mentioned. Hence we may conclude that we need not look to long tongues alone in breeding bees. We can carry on simultaneous improvements in hardiness, length of life, length of tongue, gentleness, beauty, and other points, until we reach the bounds of each. Do not, therefore, decry any one of these because it is not what you have been developing heretofore; and do not be in such great haste to develop one that you forget to keep up the others. It is true that inability to control queen-mating is a great handicap, but enough has already been done to show that progress can be made despite this obstacle; and, besides, those who make so much of natural selection must admit that it has less control of mating of queens and drones than man can exercise.

The idea is often advanced that crossing would be a means of improving varieties. This does not seem in keeping with all the facts. If crossing carries the better points of parents into the offspring, it carries the poorer ones as well. In crossing you cannot say what shall or shall not be perpetuated. From its very nature crossing does not carry characteristics bodily from either parent so much as it divides or averages those of both. If each had one good point carried to excess, the cross might make a better average; but its greater variability, resulting in more types to select from, would be offset by the greater difficulty of making the mongrels uniform and stable. Hence, there is more hope in selecting from the best among established varieties, because each step is more easily kept.

And, finally, it should be urged upon the masses of apialists to patronize the regular queen-breeders. Especially does this apply to those who live in districts rich in honey and filled with bee-keepers. You are far more at your neighbor’s mercy and under the power of wild bees than is the case in any other kind of stock-raising. The majority of your neighbors will not try to improve. No matter what you may try to do in the way of bettering your stock, you must lose it on honey. The swarms of drones from inferior stock produced around you. You must, more or less often, have recourse to the permanent improvements made by beekeepers who have succeeded in getting places where their own drones mate with their queens. You thus help yourselves, and at the same time help the beekeepers to maintain the business which you would be sure to miss should it fail through lack of patronage.

Monterey Co., Calif.

Quoting the Honey Market—Other Matters.

By Francisco Brown.

I wish to add my approval to that portion of Mr. Cooley’s criticism, on page 365, in reference to the commission-houses quoting fully up-to-date. I am particularly interested in the market quotations, but I wish them up-to-date. There is a feature in one of the bee-papers, if no more, of which I distinctly disapprove, in reference to said quotations, and that is, a house, quoting regularly, deprecating the beekeepers’ interests by cry of “overstock,” or words to that effect, and creating the impression that the price is going down, and then saying, “We are not a commission firm.” This kind of quotation is simply advertising their own honey. I wonder if the publishers of that paper would give all the rest of us a standing “ad” by telling them honey was worth so and so. I warrant the honey-dealer referred to does not tell his customers that honey is “down,” “big crop,” etc. I have dealt with commission-houses in honey for 15 years. Some, like the Horrie-Wheadan concerns, have treated me scandalously, and others have treated me remarkably fair. Under the present conditions of business we cannot well get along without the honest commission men. In some instances the producers are the gainers by consigning their product—not selling outright. How? Why, if we have a fancy, gilt-edged article, it brings the top price when buyers bid against each other. When we wish to sell outright, maybe only one or two buyers come along. For my part, I want the commission man, and I want him to know that I am alive—to my business; that the house that gets me the best price is the one that handles my honey. I have been converted to this decision more than once. To illustrate: I once had a crop of extracted honey that I wanted to sell outright. I offered it at 5 cents, and would have taken 7. After sending him a sample, a commission man wrote me your honey—I will sell to best advantage, and you will be the gainer.” I sent it. He put it into small glasses, and sold it at 16 cents, netting me 12 cents a pound. In the course of time this man sold nearly 50,000 pounds for me, selling my two combs in Dr. Miller frames.

One frame dripping with bees, and both so filled with sealed-brood there is no room in them for honey.

Dr. Miller’s Farm-Wagon Loaded with Bees from the Ouch-Apiany.
SAMPLE OF DR. MILLER'S "PAT MURPHYS."

Half-bushel (to Carmen No. 3, weigh 26 lbs.; 3 largest weighed 6 lbs. and 34 oz. The stick lying on them is a foot rule. Photographed Oct. 11, 1900.

comb honey for 16, 17 and 18 cents, when the best cash offer I received was 11 and 12 cents. 

THOSE "HINTS ON HIRED HELP."

Tell Mr. Hyde (page 564, "Hints on Hired Help in the Apiary") to be thankful indeed that his ideal helper is not to be found. If conditions would regulate hired help to do all we want to exact of them, Mr. Hyde and a lot of the rest of us would be hired help. It proves me as much as anyone to see hired help do things awkwardly, carelessly, or without thought or judgment, that a little reasoning would obviate. And yet these very things are necessary, or there would be no hired help—all would be owners—for it doesn’t cost much to start with bees. Its details, especially, are our capital. So do not expect hired help to furnish the capital, and give you the lion’s share of the earnings. A banker once asked for a cashier. Said his friend: "I can send you an honest young man, who knows nothing of banking..." "That is the man I want," explained the banker, "for I can teach him my methods and systems, and he will not have to learn knowledge that I do not want in my business." Much so with hired help, especially in the apiary. Either make a partner of the man at once, or hold yourself in reserve, and let him realize he is only a part of the machine.

LOSS OF BEES BY COMBS MELTING DOWN.

In regard to Mr. Gerelid’s loss of bees by melting down (page 560), the lack of water I do not believe had anything to do with the bees. All the colonies probably melted down within the space of an hour; when the breeze hilled they been out in a 10-acre field the loss would not have been 10 percent, I feel. We have long, hot summers in Florida, often getting up to 95 and 100 degrees, and last year, in August, it was 105 and 106 degrees on two different days, still I did not lose a single colony from melting down, and in several apiaries that I am acquainted with there was not a loss. In this line, if Mr. Gerelid will raise his colonies on benches and will put the two rows of hives about eight feet apart, then put a roof over them, extending it well over the sides, he will have a comfortable place for his bees, and also a comfortable one to work in. 

In Florida a large ant is very troublesome to bees, often destroying a good colony in a single night. If there are any to contend with, hang the benches with wire from above, instead of having legs, or attach to the posts of the shed; then dab coal-tar on the wires, and the ants will be rid of.

The most serious charge against shed-aplaries—and I have four in use, some of them several years—is the failure to get queens mated in colonies so kept. But to offset this, there is the satisfaction of having everything under cover, out of the rain, and the case of manipulation when all colonies are close together. You can have all under lock and key by using 6-inch fence-boards on the sides, leaving a space of eight inches or a foot opposite the hive-entrances, and then stretch a strand or two of barbed wire along this. For 10-frame hives allow 20 inches space each in length of building. At one end have your work-room, made bee-tight by use of burrap or mosquito netting—I use old corn and oats sacks rapped up—in which have a table and your extracting outfit. I mention the use of burrap instead of wire-cloth on account of the latter rusting out quickly in our moist climate.

Florida, Sept. 7.

SPECIAL FACILITIES FOR MOVING BEES.

It seems that the Atchleys are so inclined to the perambulator, pick-up-and-start kind of bee-keeping that they have 200 special hive-shells or cases into which bees and combs are put for moving, and taken out on arrival. As special wagons also are provided I infer that the cases are made of light materials—so light, and so much wire screen that they might crush on the road if the wagon body did not embrace each one and furnish the strength. How about this? Is it a winning idea; or is it too much expense? It stops, once for all, the smothering of bees—also the crushing of bees, so far as that comes from combs getting loose and thrashing around; but it can hardly stop new, weak combs from breaking out of the frames. Wonder if the imprisonment of each colony is supplemented by an outside screen over the whole concern. That would reduce to a very decided minimum the stinging of horses. I suppose one idea is that bees which do not get killed enroute, many of them have their lives shortened by what they suffer. If that’s the case it may pay to spend some time and money to have the honey-gatherers arrive at home Canaan in perfect order. Still my fancy hears some brother saying. "Too many traps and calamities!" and. "If I had such an outfit I shouldn’t actually get to use it, on account of the time and fuss it calls for." Page 659.

STACHELAUSAN AND LARGE BEE-CHAIRMEN.

Stachelausen seems to favor decidedly the large broad-chamber. He strikes an idea pertaining to the matter which is not familiar to all of us. Let the queen lay all she can for a spell early in the season and she wants a partial rest when the main harvest is on. On the other hand, let the queen be obliged to restrict her laying to a mere fraction of what she is capable of, and her time to avenge herself will probably come eventually; and very likely it will come just when moderate laying should mean more surplus honey. It occurs to me that the very worst cases of this could happen in a very big hive with large frames, if the colony itself came through very weak in the spring. Page 659.

LEGISLATION FAVORING FRAME HIVES.

Aha! Ye legally appointed inspector, inspect he never so wisely, cannot inspect to any purpose the apiary where all the combs are built cross-cross. That is, he can’t when foul brood is nicely beginning in 20 colonies, and none have yet got putrid or weak. To meet this case, our legislative man, Hambagh, wants everybody compelled by law to have bees on actually movable frames. Sounds seductive. But if we begin with that kind of legislation where will the end be? Where, indeed, till every dog is law-bidden to wag tail. Down, left, right, up," as the singing-master would have him? And what shall we answer if some one at the state-

HOME FROM THE OUT-APIARY.

Dr. Miller and Miss Wilson in bee-wagon used for going to and from out-APIARIES, hauling home honey, etc., drawn by "Beauty" and "Grandy."
house inquires, "Is it advisable to pass eleven laws for ten men?" Page 631.

PACKAGES FOR RETAILING EXTRACTED HONEY.

It is not so much by showing our conclusions at one another that we shall conjure up the ultimate truth from the bottom of the well, as it is by candidly laying our real experiences side by side. Mr. Davenport finds his customers don't return packages worth a cent. I find mine, pretty much all of them, so carefully conscientious in the matter that keeping a memorandum book, to show where the out pails are, seems rather a waste of time. Are my customers so much higher in their moral level than his? Impossible. What then? The full answer to that question is not likely to be reached except by a good deal of grubbing—perchance by a good many grubbers. I'll only just begin a little at one corner of the subject. Folks of low-average honesty, if they think (rightly or wrongly) that they have paid too much for the contents of a package, will gobble the package itself—as reprobial in part. I have several times tried to sell in the city by means of an intermediary, he to fix his own prices, and the result is a heavy loss of pails. Page 631.

THE LEAKY HONEY-BARREL.

Davenport's experience with barrels should be noted. All leaked; both soft wood and hard wood, although dried for two years. Wax and warrant both failed. The wax cracked; and as for the warrant, honey doesn't seem to understand the meaning of a warrant at all. Page 631.

Questions and Answers.

CONDUCTED BY

DR. C. O. MILLER, Marengo, 111.
[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail—Editors.]

Packing Bees for Winter—Other Questions.

1. 81 purchased 40 colonies of black bees, 20 in Falcon chalk hives and the rest in box-hives. The entrances of the chalk hives are only ¾ by 12 inches. Do you think that large enough for winter and summer?

2. Would you advise me to take the inner cover off of the brood-chamber and put burlap over the frames, and pack with forest leaves?

3. Would it be all right to raise the brood-chamber say ¾ inch in the summer, or would it cause the bees to loaf between the bottom-board and brood-chamber?

4. The frames have never been manipulated in these hives, and are badly braced and burr-combed. Would you advise transferring the bees and using full sheets of foundation?

5. The hives are painted red. Do you think it advisable to paint them white?

6. Would it be well to leave the packing around the brood-chamber all summer?

7. Is there any danger of using too much bi-sulphite of carbon in fumigating the honey? Does it taint the honey? About how much should one use to fumigate 100 pounds? Does it matter in regard to quality?

Answers—1. For outdoor wintering such an entrance is large enough. For hot weather, and for wintering in the cellar, I should prefer it much larger.

2. That's a good plan.

3. It would be all right.

4. If combs are straight and there is no trouble except the brace and burr combs, it would be a waste to transfer. Just cut away all the superfluous bars and braces.

5. White is generally preferred, but if hives are in the shade it makes little difference.

6. Most bee-keepers prefer to remove the packing for summer.

7. An excess is not likely to do any harm, as it evaporates rapidly. Two table-spoonfuls would be enough, or more than enough, for 100 lb. of honey if placed over the honey and closed up tight. I think you need pay little attention to quality. See interesting discussion in the report of the Buffalo convention, page 502.

8. If you are in a hurry to get the bees started, almost any honey is safe. If you trust to the bees to get them started, you may use a little brood (and you will need two or more honey super:s). There are so many ways. One way is to double up in the fall to nearly the number you want, and, if none of them die in winter, to do some more doubling-up in spring. Another way is to remove the old queen when a prime swarm issues (if your queens are clipped they will be destroyed if you let them entirely alone), and then as soon as the first of the young queens issues—which you may know by hearing the young queen pipe in the evening—destroy all remaining cells; or, return the swarm as often as it issues with the young queen.

The Home Circle.

Conducted by Prof. A. J. Cook, Claremont, Calif.

OUR COUNTRY.

If there is any one thing that should make our hearts well up in gratitude more than any other thing, it is the thought of our incomparable land. True, the home comes nearest to us, and touches our hearts and lives with the best gifts. But our American homes could not exist outside of America. Britain is the only other country that comes within telephoning reach of America. And Britain as a whole, as a land of comfortable home, hardly deserves either.

I believe the best gift or possession that any boy or girl may fall heir to, is a good education. It can be too broad or liberal. Even the day-laborer would be vastly better off with a good education. Were I to train a boy for the farm, I would have him pursue a course as thorough as that coveted by the would-be lawyer or physician. I would urge that he get all he could in the college; that he go then to the university for graduate work; and then it would do him no harm should he study abroad for a year or two. Do you say that this would likely fit him for agriculture? I know it need not, for I have the proof. Isn't it the glory of our magnificent country that any boy of will, energy and determination can, all unaided, secure all of this, if he is only so fortunate as to be an American? I know he can, for here again I have the proofs.

I have just been rejoicing in some statistics that fill my heart with gratitude as an American citizen. Our total debt now is $1,000,000,000. It was three times that at the close of the war. Yet this in the face of the fact that the war cost our Government more than $6,000,000,000, if we take direct and indirect expenses, such as pensions, etc., into account. In 1860, when our credit was at the worst, we could not borrow more for less than 12 percent. Now our 2 percent bonds are at 8 percent premium. Our present debt is $84 per capita, Russia's is $24, with a great army of people who are wholly impecunious. Even England's debt is $75 per capita; and that of France reaches the alarming

Farm Wagon Economy.
The economy of this proposition is not all found in the very reasonable price of the wagon itself, but in the great amount of labor it will save, and its great durability. The Electric Wheel Co., which makes this Electric Handy Wagon and the now famous Electric Wheels, have solved the problem of a successful and durable low-down wagon at a reasonable price.

A Good Year for Bees.
This has been a good year for bees, with the exception of a drought we had in the middle of the season. I commenced with four colonies, which I increased to 11, and got about 450 pounds of honey. The colonies are all strong, with stores of stores to take them through the winter. I wintered them in a shed built for that purpose, packed in straw, and they seem to do well.

The American Bee Journal comes promptly every Thursday, and I always watch for it with pleasure. I could not get along without it.

FRED R. HAWKINS.
Edgar Co., Ill., Nov. 7.

Selling and Shipping Honey.
My attention has been called to a letter on page 60, from H. D. Dennis, of Dr. Miller's, who speaks of his treatment by R. Presley & Co. of St. Paul. In justice to a firm which, I believe, holds the highest reputation in the Northwest, I must say that I have shipped honey and apply to them for the past three years, and not only have they always gotten me the highest market price for my shipments, and that without any unreasonable delay, but I have never had to ask twice for a check on my account.

I am aware that there are quite as many black sheep among commission men as there are inexperienced shipper, and honey, and shippers there are not unfitted. To the former I will give no quarter if I ever come across them; to the latter I will.

Extracted Honey For Sale
ALL IN 60-POUND TIN CANS.

Alfalfa Honey
This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Prices of Alfalfa or Basswood Honey:
A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 8 cents per pound; four or more cans, 7 cents per pound. Basswood Honey, 1/2 cent more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are boxed. This is all

ABSOLUTELY PURE HONEY
The finest of their kinds produced in this country.

Read Dr. Miller's Testimony on Alfalfa Honey:
I've just sampled the honey you sent, and it's prime. Thank you. I feel that I'm sending a testimonial to sell several thousand pounds of honey of my own production and then buy honey of you for my own use. But however loyal I ought to be to the honey of his own region, there's no denying the fact that for use in any kind of hot drinks, where one prefers the more wholesome honey to sugar, the very excellent quality of alfalfa honey I have received from you is better suited than the honeys of more marked flavor, according to my taste.
C. C. MELLER.
Mclnery Co., Ill.

Order the Above Honey and then Sell It.
We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

say, consult your "A B C of Bee-Culture" as to the safe methods of shipping comb honey, and don't be surprised if you get low prices for honey which arrives at its destination in a leaky condition.

Notwithstanding our efforts to introduce honey as a staple article of diet, it yet remains more or less a luxury for those who can afford luxuries can afford to insist on their grocers supplying them with clean and appetizing ones. Who can then blame the grocers for preferring a case of honey which looks clean and fresh, to one that is sticky, and consequently dirty?—WALTER R. ANSELL.

Ramsay Co., Minn., Nov. 8.

Report from Alabama—Bitter Bees.
I have had fair success this year for this locality, considering the very limited time I can give to the bees, working as I do in railroad shops, and having only evenings. For the first time since I have been keeping bees they stored a surplus from white clover. I got about one pound of honey this fall, and not one bit more, probably caused by drought, which was followed by excessive rains; then again a very dry spell, so I got no more honey till this fall, when quite late there came a good flow, which proved to be the best fall honey I ever got here, except 2 colonies out of 28 that had better honey (from yellow clover). I do not know the source of the rest, but from the time the flow commenced I noticed a peculiar flavor, and sour odor from the hives, stronger in the night: this odor is slightly noticeable in the honey, which was so very dry I had to extract, and candied solid in a week or 10 days, exactly the color of butter. I got about 20 gallons. Have you any idea what plant these bees got it from?—ALBERT E. PALAC.

Morgan Co., Ala., Nov. 5.

[We can not even guess as to the source. Perhaps some of our Southern readers can tell.—EDITOR.]

Introduction of Queens.
Mr. Editor:—I am not greatly interested in the philosophical discussion between Messrs. W. and Whitney, but I am interested in the matter of introducing queens; and if there is some way easier than the usual one I want to know about it. My most recent plan of introduction may be relied on as safe, there will be advantage in using it, but sometimes a little deviation will result in failure. In one respect his instructions seem hardly explicit enough. He says: "Do not smoke the bees constantly, but smoke and pound alternately, for two or three minutes only." That may mean to smoke two or three minutes, then pound two or three minutes and then smoke two or three minutes, and so on. If that is the meaning, will he please tell us how long, in all, the pounding and smoking is to be continued? It may, however, mean that the whole time of pounding and smoking is to be only two or three minutes. If that is the meaning, will he please tell us how long to smoke each time, and how long to pound? For it might make some difference whether

Use of Bisulphide of Carbon.

In the convention proceedings, pages 602 and 603, Mr. Burton, in speaking of the use of bisulphide of carbon as a destroyer of the bee-moth, raises the question whether any one has advocated or used it in this way for five or six years ago. I wish to state that in the files of the American Bee Journal of 12th June, 1897, there is a short statement as to its use for that purpose by G. R. Pierce of this State. Mr. Pierce not only advocates the use of it, but his present residence is unknown to me, but I thought it no more than fair to make this statement. - N. P. NELSON.

Benton Co., Iowa, Oct. 31.

Selling Honey and Other Things.

"Good evening, Mr. Hustler, I am glad you came, for if I don't talk about bees once a while I get homesick."

Now, Mr. H. lives some 30 or 12 miles from my place, but he comes this way once in a while and visits me. It is there I live in the woods near as, and he picks what trees he wants to fill his orders with; so he stays there until he has picked as many as he wants them at once, and then he has a little time to talk bees.

"At any rate," he says, "I have been stirred up lately over some articles of Doolittle's in Gleanings in Bee-Culture and the American Bee Journal. They are all on the subject of selling honey, which coincides with my idea of the way honey or anything else should be pushed out of your hands, and the 'tin' got into your pocket.

"That is all right," says I, "but a good salesman does not do business in order to sell. He has an article on selling honey, which coincides with my idea of the way honey or anything else should be pushed out of your hands, and the 'tin' got into your pocket."

Mr. Hustler replies: "That is all right," says I, "but a good salesman does not do business in order to sell, but rather in order to sell, as he advises. There are always two or three small questions, and both should be answered once for all. I think that he who might work well in one locality and not in another. For instance, suppose I sold my honey for one dollar per pound less than it would be sold in one of the wholesale in the city markets, as I understand by his advice, that is, to sell at 12 cents per pound, you quote 15 cents in the bee-paper. It costs the fancy just to market it. Now, I have 1000 pounds of honey to dispose of, and can manage, by a little push, to make it sell for 14 cents, and I could make my fortune, and my sizes, and my bee-keepers, and they would be getting rid of 12 cents per pound, and they would sell it short of 12 cents per pound, and I dispose of the balance at that price. Now, don't you see I am not trying to sell your bee-paper on the same two cents retail and 10 cents wholesale, which would be the price everywhere, should bee-keepers follow your advice? I think it would be well enough in certain localities, where every-thing else is cheap, but in my section of the country, where all sorts of goods ranging from 20 cents per pound retail, and $1.00 for 12 pounds at the stores, it would not work at all.

Add a little to that, Doolittle's
Queens for Breeders.

"Breed from the best" has been the watchword with myself as well as others. F. B. Simpson in Bee-Keepers' Review, says we're off. Given five queens from the same mother, which five queens uniformly yield about 40 pounds more than the average, and another five from another mother, which five zigzag all around from 35 below to 90 above the average, and he will breed from the first five rather than from the one that runs 90 above the average. Now, if F. B. will tell us, as I am afraid he will, that all intelligent breeders of note will agree with him, I will promptly 'bent face and stand in line with him; but if he's only giving us a chance of abusive epithets laid up for him, and a lot of brickbats to fling at his battlements. I ought to explain that he reasons that the one that runs 90 above the average is a freak that will not give uniform results, while the five of the other mother, being uniform, may be relied upon for future results.—The recommendation of F. B. Simpson is one that we have been carrying out in practice for several years. A breeder whose queens are irregular, zigzagging from one extreme to another, is one that will cause complaints from customers; but one that will give uniform results in markings.

SWEET CLOVER
And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express at the following prices, cash with the order:

<table>
<thead>

CHICAGO, ILL.

FOR GETTING NEW SUBSCRIBERS.

Red Clover Queens FOR 1902 Free
Long-Tongue Variety—Warranted Purely Mated.

We have already arranged with the queen-breeder who furnished Long-Tongue Red Clover Queens for us during the past season, to fill our orders next season. Although fully 95 percent of the untested queens he sent out were purely mated, next season all that mails for us will be warranted purely mated.

We want every one of our present subscribers to have one or more of these money-maker Queens. We have received most excellent reports from the queens we supplied during the past year. And next year our queen-breeder says he expects to be able to send out even better Queens, if that is possible. He is one of the very oldest and best queen-breeders. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, of beautiful color, very gentle, scarcely requiring veil or smoke.

Orders for these fine, "long reach" Warranted Queens will be filled in rotation—first come, first served—only granting as early in June as possible. It is expected that orders can be filled quite promptly (even better than the past season), as a much larger number of queen-rearing nuclei will be run. (But never remove the old queen from the colony until you have received the new one, no matter from whom you order a queen).

A Warranted Queen for sending us Only 2 New Yearly Subscribers

In order that every one of our subscribers who wants one of these Warranted Queens next season can easily earn it, we will book your order for one queen for sending us the names and addresses of two new subscribers to the American Bee Journal and $2.00. FURTHERMORE, we will begin to send the Bee Journal to the new subscribers just as soon as they are received here (with the $2.00), and continue to send it until the end of next year, 1902. So, forward the new subscriptions soon—the sooner sent in the more weekly copies they will receive. This is indeed an opportunity to get a superior Queen, and, at the same time, help swell the list of readers of the old American Bee Journal.

We are now ready to book the Queen orders, and also to enroll the new subscriptions. Remember, the sooner you get in your order the earlier you will get your Queen next season, and the more copies of the Bee the new subscribers receive that you can send in. We hope that every one of our present readers will decide to have at least one of these Queens.

Address,

GEORGE W. YORK & CO., 144 & 146 ERIE STREET, CHICAGO, ILL.
How frequently we see the remark: "When I get home, I shall strip everything in my yard, I select her to breed from." As an example, suppose 10 colonies to produce 200 pounds of honey; 25, 20, 150, 45, 60, 75, 45, 70, 50, 60. Suppose all are equally well bred; the queen question is not asked. In our experience, we find that the first five queens were from one mother, and the last five from another, both of which breeders had given a five-year average of 60 pounds each. It is evident that the selected queen is the least uniform, individually, and also one whose blood, the greatest variation and the greatest number between the average (it will be noted that the numbers are given, and therefore, all is 60 pounds). We know that 60 percent of her sisters gave yields below that of their mother, and we also know that the average we can expect from her must be far below her own record, and as she is the most variable (from her mother as well as from the average), we can naturally look for even a greater percent of her offspring to go below the average—in short, we are practically certain to get regression and degeneration instead of progress; simply because we are breeding from an average, not from the most consistent representative of the best blood. On the other hand, the second breeding-queen shows but two or 40 percent below the average, and therefore, we expect the average, and, therefore, their mother's yield. Therefore, I would breed from the 75-pound, the 45-pound, the 20-pound queen, and the 60-pound queen, from the second mother.

Light Laying for Feeding Queens.

"Ridiculous!" is the label that F. B. Simp- ton, Seattle, Washington, puts on the notion that keeping a queen in a nucleus will beget longevity in her offspring. Sure. But it is doing his breeders no good. It may be up to a point in a nucleus to give such a notion. He says his breeders must do their duty in a full-size hive, so he can compare right F. P. queen with the same full-size after a queen has fully established her reputation I like to give her a light job so as to keep her in a good state of health. A queen now trying to winter was born in 1897. After doing extra work during four years I felt she was too loaded to be reliable. I quit trying to save what little stuff in you. I gave her a soft job for 1901. [You are doing with your breeding just as I am, instead of doing with our best queen. —Epheus.]—Stray Straw in Gleanings in Bee-Culture.

Beeswax from Different Countries.

This will by no means always be the same. An interesting summing up of the different kinds is given in Gravenhorst's Bien- nual, which was translated in the American Bee Journal by H. G. Acklin.

In Austria the wax is found or produced in the southern portion, equaling the wax produced in buckwheat localities. The provinces of Bohemia, Moravia, and Galicia produce a soft wax, although a distinction has to be made between the wax from the western part and the eastern part of Galicia. That from the first-named locality has a pitchy odor, while the other possesses the combined odor of the other two, and is of higher quality. The best of all known waxes is that from Turkey; it is red in color, and India in price, compared with wax from Greece and its islands is nearly equal to it in quality. The southern part of France produces the best wax; the north, the best. The wax from Spain is about as good as the best produced in France. Italy produces the best wax.

The wax of India is a grayish-brown, and has almost no odor. The wax produced upon the Islands, as Timor and Flores, etc., is of importance, but the trade has not generally been exported to China, where a great deal is consumed and also produced.

Egypt. Morocco. Barbary States furnish a considerable quantity of very impure wax. Beeswax from the Senegal is rather dark in color, accompanied by an unpleasant odor. Very good wax is produced in Guinea; it is hard and very difficult to obtain. The best American wax is usually dark and difficult to bleach. From Guadeloupe black wax from wild bees has been marketed. It can not be bleached out.

CONVENTION NOTICES.

Chicago — The executive committee of the Chicago Bee-keepers' Association has ordered that the next meeting be held all day and evening, Dec. 5, 1901, at the Grotto Club-room. This is arranged on account of the low rates to be for force them for the International Live-Stock Exposition in Chicago at that time (Nov. 30 to Dec. 7), being one fare plus $2.00 for the round-trip fare to send 100 to 300 bee-keepers near Chicago, and should result in the largest attendance ever had. C. C. Miller and Mr. C. P. Dadday have promised to be present. Let all come.

HERMAN F. MOORE, Sec.

George  W. Young, Pres.

MINNESOTA — The Minnesota Bee-keepers' Association will meet in Plymouth Church, Cor- sth St. and Nicollet Ave., Minneapolis, Minn., Wednesday and Thursday, Dec. 1 and 2, 1901. Mr. W. Z. Hutchinson will give a stereopticon lecture, and an exhibition of good preparations and wasps. A program is prepared and now in the hands of the printer. Joining the National Bee-keepers' As- sociation every bee-keeper in the state is invited. Chairman Executive Committee.

Naples, N. Y., Frederick Grimm Finer.

New York — There will be a bee-keepers' con- vention (annual) held in Canandaigua, N. Y., by the Ontario Co., N. Y., by Bee-keepers' Associa- tion of Ontario, N. Y., Dec. 1 and 2, 1901. R. A. Burne, and Muth, Canandaigua, Ohio.

Honey and Beeswax

MARKET QUOTATIONS.

Honey

CHICAGO, Nov. 1.—The market is easier in tone, while prices are nominally the same, but strong is shated to effect sales. Some caros of honey come to the Eastern market, and are diverted to this and surrounding points, which is heavy a depressing influence to the market in 141c for best grades of white; light amber, 125c; dark amber, 50c; white, 45c; buckwheat, 30c, according to quality, flavor and pack- age; light amber, 45c; amber and dark, 50c. Beeswax.

CINCINNATI, Oct. 25.—The honey market is rather dull on account of the warm weather. Export sales continue to be the only source of revenue from 50c; better grades alalfa waxes from 50c; white clover from 80c. Fancy white comb honey sells from 135c.

C. H. W. WHREE.

ALBANY, N. Y., Oct. 25.—Honey in good de- mand, and the market is on an even keel for some time to sell. Grocersmen are stock- ing up and will buy lines, when rates allow buyer enough to piece out. Fancy white comb honey sells at 145c; buckwheat, 135c. Exported, white, 80c; mixed, 75c; buckwheat, 60c; white, 50c. Kansas City, Oct. 25.—Near comb honey is arriving by express in small quantities from Iowa and Colorado, and selling at $3.50 per case in a re- tail trade. A call is made for fancy white comb offered caros at 85c; per pound, f.o.b. Cal- ifornia, 60c to 50c, depending on the grade and quality of any sales having been made thus far. The production of extracted honey seems to be quite large this year in Colorado, Utah and California. PEYBROE BUCKS.

NEW YORK, Nov. 4.—Comb honey is in good demand, and the market is on an even keel for some time to sell. Grocersmen are stock- ing up and will buy lines, when rates allow buyer enough to piece out. Fancy white comb honey sells at 145c; buckwheat, 135c. Exported, white, 80c; mixed, 75c; buckwheat, 60c; white, 50c. Blaire, Scott & Lee.

SAN FRANCISCO, Oct. 25.—There is very little demand for stocks with ample supplies at the present writing. Fancy No. 1, in cartons, 150c; No. 2, in cartons, 125c, No. 1, 25c; very little No. 1, no longer received; glass-from stock, 125c to 75c; fancy white comb honey, 95c to 75c. PEYBROE BUCKS & CHANEY.

DREXEL, Oct. 25.—There is very little demand for stocks with ample supplies at the present writing. Fancy No. 1, in cartons, 150c; No. 2, in cartons, 125c, No. 1, 25c; very little No. 1, no longer received; glass-from stock, 125c to 75c; fancy white comb honey, 95c to 75c. PEYBROE BUCKS & CHANEY.

DETOUR, Oct. 25.—Fancy white comb honey, 145c; No. 1, 135c; No. 2, 115c to 10c; No. 3, 25c; No. 4, 15c; exported, white, 60c. PEYBROE BUCKS & CHANEY.

SUNNYVALE, Oct. 25.—Fancy white comb honey, 145c; No. 1, 135c; No. 2, 115c to 10c; No. 3, 25c; No. 4, 15c; exported, white, 60c. PEYBROE BUCKS & CHANEY.

SUNNYVALE, Oct. 25.—Fancy white comb honey, 145c; No. 1, 135c; No. 2, 115c to 10c; No. 3, 25c; No. 4, 15c; exported, white, 60c. PEYBROE BUCKS & CHANEY.

A New Bee-keeper's Song—

"Buckwheat Cakes and Honey"

Words by EUGENE SECOR.
Mus. by GEORGE W. YORK.

This song was written specially for the Buffalo convention, and was sung there. It is written for organ or piano, as have been all the songs written for bee-keepers. Every home should have a copy of it, as well as a copy of "THE HUM OF THE BEES in the APPLE-TREE BLOOM"

Written by EUGENE SECOR and Dr. C. G. MILLER.

Prices—Either song will be mailed for 10 cents (stamps or silver), or both for only 15 cents. Or, for $1.00 strictly in advance payment of a year's subscription to the American Bee Journal, we will mail both of these songs free, if asked for.

Texas Bee-Keepers.

We beg to announce the opening of a branch office and warehouse at 438 W. Houston St., San Antonio, Texas. Rates of transportation from Medina in less than car-load lots are high, and it takes a long time for a local shipment to reach Southern Texas points.

Low Freight and Quick Delivery.

To secure these two necessary advantages—low freight and quick delivery—and to be better prepared to serve the interests of our Texas friends, is our reason for establishing this new branch office. No other point in southern Texas is better adapted to serve as a distributing point. It has four great railroads—the Southern Pacific R. R. west and West—the International and Great Northern R. R. from Laredo up through San Antonio and Central Texas, the San Antonio and Arkansas Pass R. R., and San Antonio and Gulf R. R. It also has the American, Wells-Fargo and Pacific Express Companies.

Our Managers.

We have secured as managers Mr. Udo Toepperwein, formerly of Leon Springs, and Mr. A. Y. Walton, Jr., both of whom are well known to the bee-keepers of South and Central Texas. They are also thoroughly familiar with practical bee-keeping and all matters associated with it, and any orders sent to this branch will receive prompt, careful attention.

Our Goods.

As usual our motto is to furnish the best goods of the most approved pattern. We do not undertake to compete in price with all manufacturers. Bee-keepers have learned that it does not pay to buy cheap supplies, for a saving of 10 cents on the first cost of a hive may be a loss of many times this amount by getting poorly made and ill-fitting material. Every year brings us many proofs that our policy of "the best goods" is a correct one.

Our Catalog.

Very few changes in prices will be made in our new catalog, so do not delay your order, but send it at once. You will be allowed a refund if lower prices are made, and in case of higher prices ruling in the new catalog, if any, you will secure the benefit by ordering now. Catalog and estimates may be had by applying to the address given below.

Our Invitation.

Whenever you visit San Antonio you are invited to call at our office and make it your headquarters. Here you will find a display of Apisarian Supplies not equaled elsewhere in Texas. You will also find on file the leading bee-journals to pass pleasantly your leisure time.

Spanish Catalog.

Some of you may read Spanish, or have a bee-keeping friend who does. If so, call for our Spanish catalog. It's sent free.

FACTORY AND HOME OFFICE:

THE A. I. ROOT CO., Medina, Ohio.

Branch Office:

THE A. I. ROOT CO., San Antonio, Texas, 438 West Houston Street, TOEPPEPERWEIN & WALTON, Managers.

GEORGE W. YORK & CO., 144 & 146 Erie Street, CHICAGO, ILL. are headquarters for ROOT'S BEE-KEEPER'S SUPPLIES IN CHICAGO. Send to them for their free Catalog.
MR. J. T. ELLIOTT AND APIARY, OF BROOKE CO., W. VA.—(See page 754.)
American Bee Journal

Weekly Budget

Editor W. Z. Hutchinson gave us a short call on Saturday, Nov. 16, when on his way to attend the meeting of the Colorado Bee-Keepers Association at Denver, held last week.

Eugene Secor, the general manager of the National Bee-Keepers Association, was recently elected to the Iowa Legislature by a handsome majority. He expects to spend the winter in Des Moines, the State capital.

Mr. C. M. Scott, for some years the manager of the G. B. Lewis Co.'s bee-supply branch at Indianapolis, Ind., has bought the business at that place, and will continue it under the name of C. M. Scott & Co. Mr. Scott is very highly commended by the Lewis Company, and we trust he may continue to do a successful business.

Mr. W. L. Coggshall, one of New York State's most extensive bee-keepers, has been in very poor health for some time. Late he went to a sanitarium about 40 miles west of Chicago, where he is receiving treatment. On Nov. 15 he wrote us that in two or three weeks his physician expected to send him home well. Mr. Coggshall's many friends will be delighted to hear this. If well enough he may attend the Chicago convention at the Briggs's House, Dec. 5.

Mrs. N. Neilson, of Sac Co., Iowa, died of cancer Nov. 11, after months of suffering. In 1882 she married Mr. N. Neilson, who, with five children, are left to mourn her departure. She was a member of the Congregational church from her young girlhood. A local newspaper says Mrs. Neilson was an amiable, thoughtful, patient, loving wife and mother, showing in her life the noble qualities of a high Christian character, and winning unto herself a host of warm friends who deeply feel their loss. Our sincerest sympathy goes out to the stricken husband and children, who, it is a satisfaction to note, "mourn not as those who have no hope."

Dr. C. C. Miller has this to say regarding the meetings of the Board of Directors of the National Association at Buffalo, and also something about certain discussions in open convention:

Mr. Editor—These unfortunate Directors' meetings held while the convention was in session at Buffalo, deprived me of the privilege of hearing a considerable part of the discussions, which probably makes me appreciate all the more the excellent and full report you are now giving in the columns of your journal.

Referring to a discussion on page 726, I may say that I have many a time seen a hive containing a nucleus in place of a swarming colony, &c., and not long ago I entered the nucleus, and in no case have I ever known the queen of the nucleus to be molested in any way. The old colony was removed, and the queen that hatched with the swarm was also disposed of. If it is not often that as much real information is given in so short a space as in the discussion of the succeeding topic. All of the items mentioned are useful in trying to determine the presence of a virgin queen when she can not be found. Perhaps none of them may be pleased upon reading the report, but they will help. The one that I have depended upon as much as any other for years, is the one mentioned by W. L. Coggshall—cells polished out in the central part of the brood nest ready for the queen to lay in; and this may be several days before the queen is seen. I have often times when she is hardly a day old. Some-what strangely, I do not remember to have seen this mentioned in print, and this shows one good thing in conventions, bringing out from such men as W. L. Coggshall things that they would never take the trouble to write.

C. C. Miller.

Mr. J. M. Hooker, as may be seen in a late number of the British Bee Journal, has sailed from England for his new home in America. His loss will be keenly felt by the British Bee-Keepers Association. Mr. Hooker having been one of the seven who originally met to organize the Association, and one who was always foremost in the movement to establish modern bee-keeping. Mr. Garrett probably spoke the general feeling when he said that to hold a conversation without the presence of Mr. Hooker was a mere invention, and that everybody who had been accustomed to see that gentleman there would feel that the cause had suffered a severe loss by his absence. Mr. Hooker is cordially welcomed to these shores.

Mr. J. T. Elliott and Apialy are shown on the first page this week. When sending the photograph, Mr. Elliott wrote as follows:

Editor York.—I send you a picture of my apiary, but it does not show up very well, as it was impossible to get a good view showing all the hives, etc., on account of the trees and shrubbery. I keep my bees on a city lot, so I have not much extra room for hives, but I have them under young apple and peach trees, just over the bank at the edge of the garden. The hives being down just over the edge of the bank is why they do not show up better.

We have 24 colonies, all in one row, and work them for both comb and extracted honey. As I am employed as clerk in a railroad office, I do not have much time to develop my apiary. My bees are on the lot only a very few minutes at the noon hour, and a little while mornings and evenings, when the weather is favorable. My greatest pleasure in working with the bees, and find them very profitable, also in supplying my table three times every day with honey, which is more healthful than jellies, jams, etc. Then I can dispose of all my surplus honey to my British Bee-Keepers Association. My bees did fairly well the past season, the surplus all being from basswood and sweet clover.

J. T. Elliott.

The Delineator.—The Christmas number of the Delineator is about the first of the special Christmas issues. It is a beauty. The cover is a most artistic production, showing a beautifully gowned woman, standing gracefully in a brilliantly lighted salon. Two charming love letters, followed by a great deal of advice regarding Christmas Gifts; timely pointers on Cookery; Winter-time Care of Plants; all the fashions of the day, interpreted into simple language, can be found in the Christmas number of the Delineator. It is a splendid magazine, satisfactory inside and out. There is no magazine for women at present that can stand up against it as a page. As a Xmas gift itself, it bears its own recommendation. $1.00 a year, or 15 cents a copy. Butterick Publishing Co., Ltd., 7 to 17 W. 13th St., New York, N. Y.

National Bee-Keepers' Association:

OBJECTS:
To protect and promote the interests of its members.
To prevent the adulteration of honey.
To prosecute dishonest honey-dealers.

EASTERN COMMITTEE.
E. Whitcomb.
W. T. Hutchinson.
A. L. Root.
E. A. Abbott.
F. A. Noyes.
E. K. Root.

EXECUTIVE COMMITTEE.
Ernest R. Root, President.
R. M. Stockey, Vice-President.
Dr. A. B. Mason, Secretary, Toledo, Ohio.

Eugene Secor, General Manager and Treasurer, Forest City, Iowa.

Membership dues, $1.00 a year.

If more convenient, dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: I have every reason to believe that it would be a very good idea for every bee-keeper to wear one of these buttons, as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of some of your products. I wish you could give the bee-keeper a superior opportunity to enable many a person is regard to honey and bees.

The picture shown herewith is a reproduction of a most interesting conversation that we are furnishing to bee-keepers. It has a pin on the underside to fasten it. Price, by mail, 6 cents; two for 10 cents; or 8 for 25 cents. Send all orders to the office of the American Bee Journal.
The Chicago Convention is to be held next week, and the papers will be presented on Monday at 10 a.m., at the Briggs House, northeast corner of Randolph St. and Fifth Ave. There will also be an evening session.

We are expecting a large attendance, as there are many bee-keepers in Chicago and vicinity, and we have received notice from a number of distances who expect to be present.

Come, and bring with you as many questions as you would like to have answered. Dr. Miller has promised to come, and bring with him a good supply of answers, which, with the other able experts that are expected to be present, ought to be of no difficulty about taking care of several boxes of questions. These will also be a few papers on practical topics, that will help start interesting discussions.

Come along, and help make this meeting of the Chicago Bee-keepers’ Association equal to the best “Northwestern” ever held.

Combing Honey by Weight or Case.—On another page Messrs. A. A. Burnett & Co. write on the subject of selling comb honey by the case or by weight. We agree entirely with them. In our opinion there can hardly be any valid reason advanced in favor of selling comb honey by the case to wholesale dealers, or to retailers. We have handled quite a good deal of comb honey, but have never bought any by the case, except in one instance where we had it sold before getting it ourselves, and our buyer being willing to take it by the case, we have not been able to say if it would be of any advantage to the producer to sell by the case. Our own grocery trade we do not think that we could be induced to purchase honey by the case. We would have to sell it out by weight to the retail grocers.

Sometimes selling by the case proves a great loss to the producer. We remember once hearing of a carload of comb honey that was sold to a certain firm by the case, on which they cleared beyond a fair profit the sum of $400; and just because they sold it out by the pound, the ear of honey avenging enough more pounds per case to equal that amount, or more, to pay the freight. Had that ear of honey been sold by weight in the first place, as it should have been, the producers would have been about $400 better off. So much for the producers standing in their own light.

We hope that bee-keepers will see that it is to their best interest to deal squarely, and not encourage a kind of buying and selling that can not well be defended as honorable and upright. Gains gotten by any other than straight dealing can be only of temporary benefit. The firm or individual whose policy is ever tainted with deception, or by what is known as “smart dealing,” has its days already numbered. “What shall it profit a man if he gain the whole world and lose his own soul?” There are some things of more value than dollars—their worth can not be estimated in money. A man is really worth what he is, not what he has. True character and a good reputation are everything in this life, and a blessed assurance of the higher and better life that is to come.

A Good Hive-Cover is a thing that is not in universal use, and the interesting discussion reported upon page 725 of this journal shows that the demand for a satisfactory cover is becoming so insistent that manufacturers can hardly afford to ignore it. The trouble has been that the matter of cost has cut too large a figure. A plain board with cleats on each end can be had for a small sum, and in some respects it makes an excellent cover; but no matter how many good qualities it may have, a single bad quality, if bad enough, is sufficient to condemn it. The plain board cover has more than one bad quality, but one that is sufficient alone to condemn it is that it will twist. Cleats, if strong enough, may prevent warping, but cleats of cast iron can not prevent twisting, if a board is inclined to twist. Unfortunately too many of them have that inclination, and when a cover twists so that one corner lies a fourth inch or more above the hive, the day of satisfactory service for that cover is over.

Perhaps the easiest way to secure a non-twisting cover is to have it consist of two layers of wood, the grain of the two layers running in opposite directions. A dead-air space between these two layers will make the cover cooler in the hottest weather, and warmer when the outside temperature is lower than that in the hive. Such a cover covered with tin and painted might be furnished at a cost not beyond reach, and it is possible that some kind of painted paper might be nearly or quite as well as tin. Now that attention is so strongly turned in that direction, the right thing will probably be in sight before long.

The Minnesota Convention is to be held Wednesday and Thursday, Dec. 4 and 5, 1901, in Plymouth Church, corner 5th St. and Nicollet Ave., Minneapolis. The first session is at 9:30 a.m. on Wednesday. A really good program has been published in connection with that of the State Horticultural Society. This is a good arrangement, both organizations meeting on the same dates.

Besides the question-box and usual business of the sessions, we find the following special features on the bee-keepers’ program:

-Song,—“The Honey-queen and the Bee”—Miss Edith Dexter.
-Should We, or Should We Not, Join the National Bee-keepers’ Association?”—C. Thielleman.
-Song.—Wm. Reuter and Miss Mary Reuter.—Some Facts in Favor of Joining the National Bee-keepers’ Association.—J. T. West and Mrs. H. G. Acklin.
-President’s Address.—Wm. Russell.
-Song.—“Buckwheat Cakes and Honey”—Master Eddie Holmes.
-Some Problems and Queries in Practical Bee keepmg.”—J. W. Murray.
-Song.—Miss Julia Moonen.
-Bagpipe Selections.—Wm. Russell.
-Song.—“Hymn of the Bees in the Apple-Tree Bloom”—Little Miss Ethel Acklin.
-Distributing of the Honey Crop to the Best Advantage.”—A. D. Shepard.
-“Shade and Ventilation”—Walter R. Nelson.
-Wintering Bees.”—J. B. Dexter.
-Bucking Against Nature with Bees.”—John Collins.

Nominations for the National.—Editor Root, in commenting on our suggestion about having the national convention make nominations for the election of general manager and three directors each December, suggests that it might be wise to change the general manager very often. All right; then re-nominate him among the three candidates; and also re-nominate among the nine the three directors whose terms expire, if thought best.

See page 69 for our former editorial on this subject. It is a matter worthy of earnest consideration.
The Buffalo Convention.

Sept. 10, 11 and 12, 1901.

(Continued from page 743.)

The Wednesday evening session was treated to an exhibition of stercoriposition views by Pres. Root and W. Z. Hutchinson.

THIRD DAY—MORNING SESSION.

The convention was called to order by Mr. Root, who called upon Dr. Miller to offer prayer.

The Canadian members present were asked to rise to their feet, and, on being counted, there were found to be 12.

F. A. Gennill, of Ontario, Canada, then spoke as follows on the subject of Wax-Presses and Their Use.

In regard to the matter of wax presses, I might say that some years ago my bees had foul brood. Of course, that is a bad disease, but it is no disgrace for a man to let it have it, if it is a disease to keep it; and I tried up many of the old combs I found that I could not get all the wax out—that is, those containing many cocoons and pollen—without using pressure in some form. I looked over the bee papers and bee-books, and among others, the 'A B C of Bee-Culture,' and I saw some illustrations of old presses, the Hatch press, and I combined the two and made a press, the Hatch-Gennill press, which I think it would pay any one to use. I wouldn't say that press alone, but I believe in some kind where strong pressure is used.

I might say that I tried the Doolittle plan of melting the old combs in a gunny-sack, using a large press, and as the wax being boiled the lever was brought to bear on the wax and the wax squeezed out. I tried the plan of putting them in gunny-sacks and sinking them in water. It was very good; of course, it requires a little boiling in order to get all the wax out. It is a better plan, maybe, than using the steam wax press where the refuse is allowed to remain on the bottom, for this reason, that if the gunny-sack is sunk in the water, but not too deep, the wax will rise to the top; in the other case, if you use the steam, the refuse will go to the bottom and remain in the cocoons, and stay there unless pressed out.

Then I tried other machines, the Ferris and one or two others, and I have nothing to say against any machine, only that my experience proved that where I used either boiling water or steam I had to use the pressure in order to get all the wax out. I also melted combs in the Board man, still I found that with old combs with cocoons and a large pollen-mass it was impossible to get all the wax out. If left in the extractor for a week there would still be some there; the cocoons acted as a sponge and retained it, so that I think those that have been using the solar wax-extractor for old combs and the honey-extractor We have lost quite a little bit of wax. I was quite amused at Mr. Root's reference to Mr. Mendelson buying up the slum gum in California and using a press that paid him to get the wax out of it.

I don't know that there is much that I can say. If there are any questions that you wish to ask I would be happy to answer them. I might say that my first article in regard to this matter appeared in the Review, and since that time Mr. Root has been in California and he has fallen in line with the same ideas that I had in regard to the press. We had some correspondence in regard to it, and I believe he is now manufacturing one that I believe is a good thing. I hope to have the pleasure of trying it shortly.

F. A. Gennill.

Pres. Root—This question about being able to get all the wax out of slum gum is a very important matter, because bees are throwing away dollars, and now they have come to know there is wax in that slum gum.

A Member—How do you avoid getting propolis in the wax?

Mr. Gennill—The propolis will come out with the old combs, to a certain extent. In our country [Canada], however, we don't have a great quantity of it.

Mr. Betsinger—How long do you think it will take to pay for such a machine? How much does this machine cost?

Mr. Gennill—About $3.50 to $4. But Mr. Root's machine is an improvement, in some ways. Of course, it will cost more.

Dr. Miller—Suppose that you have combs enough from which you get about 100 pounds of wax in the ordinary way. Now the slum gum from that contains yet how much wax?

Mr. Gennill—That depends upon the method you employ. If you use the plan for waxing it, the wax in the bottom of the boiling water you will get more if you boil long enough, than you will get out of a steam or solar extractor, where you allow the refuse to remain in the bottom of the steamer, for the simple reason that it is retained there the same as a sponge retains water. I found that I could get more wax out by boiling according to the Doolant plan. I would get about 3/4. I can get a third more, easily, than with the steam process, and a third more by using the press.

Dr. Miller—That is, a third of the wax is still left in the slum gum?

Mr. Gennill—that is, it would be left in Mr. Root's steamer he did not use the pressure.

Mr. McEvey—Are wax presses the bee-keeper, in your experience, able to afford to do without a press?

Mr. Gennill—I say any man that has any colonies at all, and has any old combs to melt up. Where one has any old combs that have been used for some years, and that contain pollen and cocoons, I think that man should use a press.

Dr. Miller—How many colonies?

Mr. Gennill—25 colonies, anyway.

Dr. Miller—How long should the wax be boiled when the pressure is used on it?

Mr. Gennill—I allow it to come just to a boil, and boil smartly for a short time, and then get it to flow freely. After you apply the pressure it doesn't require boiling very long.

Mr. Betsinger—Five minutes, probably.

Mr. Gennill—About that.

Dr. Miller—I see the instructions are, in making the pressure, to turn down a certain amount, then wait awhile and then apply it. Is any harm come from pressing too rapidly?

Mr. Gennill—I find that you have got to give the wax a little time to come down from the combs. Now, there is just one point there. After you have pressed all you think you can out of it, if you use the steam, you can boil it after it settles down. Any more wax that will settle down, and that will help to free any wax that it may still contain. Then you can apply pressure again, or you can turn over the refuse two or three times and then apply it, but it will do no harm to try the hot water.

Mr. Betsinger—By using old combs and putting it through this pressure would there be any color in the wax?

Mr. Gennill—Oh, no, it would be perfectly yellow. It is squeezed right through the combs. It is forced right through and it is purest wax, course, you will understand, in the press it is confined in a small sack that acts as a filter or strainer.

Mr. Betsinger—Can all the propolis go through that, too?

Mr. Gennill—O yes, it will go through.

Mr. Davidson—Do you think such wax is just as good for making foundation as other wax?

Mr. Gennill—I couldn't see any difference. I don't see why it should not be. There is nothing in it but pure wax.

Mr. Davidson—I find that with several grades of wax used in sections, it does not receive as acceptance readily as others, and I had the idea that section foundation made with old wax, that is, wax from old combs, would not be accepted as readily as foundation made from newer wax, that is, from newer combs.

Mr. Gennill—I must confess that I haven't had any experience in that line. Dr. Miller—in our old combs, we are directed, or have been in the past, to break them up carefully, and to soak them beforehand. Now, the melting of the desirable or advisable in this method?

Mr. Gennill—It is not required where you use pressure.
the wax from the press the softer the wax. The wax from cappings should always be used in foundation for sections. It is nicer.

Mr.; Gemmili—The cappings from combs made with this press and wax extractor are a great deal harder. There are other things in the cappings besides wax.

Mr. Shwader—I was speaking of old wax that is gotten out by any process. Doesn't wax by age lose something that it requires?

Mr. Gemmili—I couldn't say in that respect.

Dr. Miller—Now, I think you are all such careful bee-keepers that you never have combs melt in the sun. A certain bee-keeper who lives where I do, sometimes has that happen, and the thing that surprises me is the amount of yellow wax that the sun-wax-extractor will get; and another thing that surprises me is the softness of that wax, and I very much doubt if there is any hardness increased in that wax.

Mr. Gemmili—I think that is correct.

Mr. Callbrene—Should the combs be soaked beforehand, or doesn't that make any difference?

Mr. Gemmili—It doesn't make any difference, as far as I know; you may use boiling water and pressure, provided you use pressure afterwards. Of course, according to the Dadant plan, you soaked the combs in vegetable oil before drenching them in boiling water, and then immersing them in the boiling water. But the point is this, that if you use pressure you don't require the amount of heat that you would if you didn't.

Mr. Villa—I was going to say, I think the foundation that was set in sections and was not accept was a soft grade of foundation, and my idea was that the wax by age loses something that the bees require in order to mould their foundation over; and a foundation not having that, the bees will not work it as rapidly as they will foundation made from new wax. This is my idea, because I do not think you would work certain foundation.

Mr. Gemmili—I would like to say that since using the press, I have noticed a large number of bee-keepers who were retaining old combs that were defective in some way, and I might mention Mr. Hall, of Ontario, for one; who was going to make foundation one day, and I got my son to go down to assist him. My son took the press down with him, and all the time he was making foundation in the forenoon he was talking press; and at the noon-hour my boy went out and got the press a-going, and got a lot of the slumgum that Mr. Hall had been throwing out of the press during the time of getting it out of it. Mr. Hall looked at it a moment, and said he would get a press. He got a press and has melted up several times since then, and he says, as far as I know, he doesn't want any old combs, and I think your boy is very right.

Dr. Miller—This gentleman asked about foundation being acceptable to the bees after getting old. I had some foundation that was put in sections four years ago, and I kept it where it was dark, and I couldn't see but what the bees accepted this foundation as readily as they did new foundation put in this year.

Mr. Benton—I want to ask Mr. Gemmili if it wouldn't answer, in applying the new press, to put the wax extractor instead of being obliged to watch it and screw it down, so that it would act automatically?

Mr. Gemmili—You would have to use great pressure, and it would have to be coming down constantly.

Mr. Benton—It would be coming down, or would it?

Mr. Gemmili—You would require a great weight. People have no conception of what a screw will do in regard to the amount of pounds that it will pull up, and you want to be sure, in getting the press, to get a machine that will have a strong screw. You will be astonished at the amount of pressure you can use. I wouldn't recommend a weight at all; you would want to have hydraulic pressure, or something of that kind, if you were going to use a weight instead of a screw.

Mr. West—I endorse the pressure of getting out wax. I have used the pressure, as has been mentioned, of pressing foundation for the wax to rise to the top, and in every case I find it is necessary now and then to raise the screw to let the water in. But since I have been using the pressure system, I have had the habit of using a radically different way of melting our wax. We use the same tank, put our hot water and combs in, and let them melt, and then when the pressure is high enough, we take the cheese-cloth, on one side, and we use a large dipper—a 3 or 4 quart dipper to dip it—and get that cheese-cloth and put the pressure up there, and draw the wax out in another place. We get the wax, we think, pretty nearly clear in that way.

Mr. Gemmili—Of course, I am not informed as to the best methods of applying the screw, but I say apply the pressure in some form.

Mr. Benton—The reason why I asked the question, again, was weight. We were asked to give our German friends some credit. We are apt to poke fun at them and call them slow, but they have been using the wax-press all the time.

Mr. Gemmili—I am not a German, and have not come in contact with any German bee-papers, but I understand that Mr. Holtermann, formerly of the Canadian Bee Journal, had made some copy of the old German press, and, of course, they were using the screw there long before I knew anything about it in that form.

A. I. Root—The Germans were original in the use of this press in connection with steam and hot water, and because of the different terminologies and names we have the machine "German," because we thought the credit ought to go where it belongs. I found they had used it in 1847.

Dr. Miller—If you are going to quote the Germans, I think you ought to go a little further and say that many of them are being sold, and the abandonment of steam presses for hot water and they are now saying that hot water is better than the steam—under pressure, you understand.

Mr. Gemmili—By putting the combs into the gummy-sacks and sinking them under water more wax will be secured than in the steamer; the wax will rise to the top, and if you do the pressing in the hot water the water will carry the wax to the surface.

W. L. Coggshall—Hot water is the thing to do with, that I think. It will do it much better than steam, with me. I use an ordinary kettle for a boiler, and can make 100 pounds of wax in half a day without any trouble.

Dr. Miller—Does Mr. Coggshall use pressure?

W. L. Coggshall—No, I haven't used pressure, but I think it is the proper thing to do. I usually put the pressure on by fastening a stick across the top of the kettle, and I put a kettle over the top and take the wax off the top. It is the proper coper. I just put an ordinary strainer over the top and move it around and take the wax off.

Mr. Lam—What kind of a kettle do you use?

Mr. Coggshall—A four-barrel kettle.

Dr. Miller—Was that called the old Jones extracting kettle? Was there pressure used?

Mr. Lam—There was pressure used. I have nothing against the pressure, but the press I had was too small for the purpose, and it melted the wax too fast. I've been letting the steam melted it more slowly, and for that reason I melted the wax first, then poured it into the kettle and put on the pressure.

Mr. Craig—The first set of wax-presses that were sent out, that is with the pressure, was an attachment to what is known as the old Jones press, and we found that it required too much heat to generate the steam and so we discouraged that, making a machine with a copper bottom that sets down in a kettle of water; and this, we find, works very much better, and requires very much less heat.

Mr. Alpaugh—Mr. Gemmili has told me more than I could tell you, about five times over. I melted only a few old combs, and I did it with hot water and pressure, on Mr. Gemmili's principle.

Mr. Gemmili—Mr. Alpaugh has an idea in regard to this matter that I should like to hear.

Mr. Alpaugh—My idea would be to have a large melting tank, something you could get lots of stuff in, anyway, and have a division in this, and in the division a pair of rollers set perfectly tight, so that they would work on the principle of a wringer, so that you could wring the stuff through from one side to the other and keep the wax bath hot, which is the only way to melt quantities and not to have too slow a job. My idea was to feed it through rollers in a thin layer and grind it through under low pressure, the same as wringing out clothes.

Mr. McEvoy—How would it to do to put the combs through a cutting-box first?
Pres. Root—I believe Mr. Alpaugh is on the right track. In order to put pressure on the combs you have to get them close enough together so that the wax melted from one panel would cover the other. I don't think it perhaps would be the depth of a basket, and when squeezed down should not be more than an inch thick. Mr. Alpaugh has the right idea of having a waxed paper or their fellow that would yield enough so that this slumgum could go through in thin layers.

D. H. Miller—I believe that Mr. Alpaugh has a good thing and a bad thing together. I believe he has the right idea in the one respect, that you want to put the combs close enough together to get pressure on the slumgum. That's the trouble with the wringer business. You attempt to put a towel through a clothes wringer and you get the least start the towel will go through; but suppose you take two towels on the half of it will go through, and there is nothing to catch the next particle, and it will simply squeeze and pack, in order to get through the towel. I don't believe you could get the thing to go through, but I believe Mr. Alpaugh has the right idea, that there should be some kind of arrangement that will get the wax out in thin layers.

D. H. Coggshall—I take a bran-sack or a gunny-sack and re-sew them so that they won't rip at the edges, and put the wax or combs into that; then I make a large particle of wax in the slumgum, use a large caldron kettle and put the sack of wax in, and keep the upper one going, working back and forth, through the squeezing and keep working it back and forth. Of course, if I have black combs there is not so much wax in them. I have tried every way, boiling it under water. There are lots of articles particles of wax in the slumgum. You have to work it under water while you are pressing it. I keep two sacks, one heating while I am squeezing the other. I get lots of water in the can I am cooling it in. Then draw the water off at the bottom and take the wax out. I made a division line in the wax; made a trench 3 feet long, use a large caldron kettle and put the sack of wax in, and keep the upper one going, working back and forth, through this squeezing and keep working it back and forth. To make the squeezers I take a board a foot wide for the bottom one, and the upper one not quite as thick. I put them on the ground and pound them all up; put them under hot water, and squeeze them in these squeezers. I can get it that way. I think that is the only correct way to get it.

Mr. Alpaugh—I understand you to say there wasn't so much wax in black combs.

D. H. Coggshall.—Of course; there isn't much refuse in cappings; there would be a little.

Mr. Alpaugh—You mean to say a comb of wax, if you put it in after the nights got so cold, the bees wouldn't go up in the feeder, but by placing the feeder underneath so as to bring the food within an inch of the frames, a night in October when the ground was covered with white frost, they would go down into this and take up perhaps seven or eight pounds of wax in some nights. Whereas, if I put it above they would withdraw, and I would lose the colony by not feeding early. I like the combs all sealed. It is work, but it pays.

Mr. Gemmill—The only way is to keep pressing until you can't get any more out of it. I don't care how much you can get. If you put your finger into the fire you will see there is a little left in it.

The chairman was called from the room, when Mr. Gemmill presided.

Mr. Gemmill—The wax has been brought in to this room. The winterer had all the wax gathered together and wished to remodel it. I generally used the steam extractor without the pressure. I made a few schedulers. In making hot jelly in my lines of top of that I put a wire-clothes basket sunk down, and inside of that I laid a very fine piece of old cheese-cloth; then I put this into the steamer, and in the lower portion I put on the lid of an old pot so as to keep the wax from running down into water, and I retained all the refuse, and a lot of the propolis, too. The problem of it, there would be very little pollen. The wax is forced out of the pollen and the coconuts. There will be a little propolis and some mechanics of dust.

W. L. Coggshall—To clarify wax, a teaspoonful of sulphuric acid will do for 100 pounds. Be careful not to put in too much.

Mr. Calbreath—What kind of a vessel do you use?

W. L. Coggshall—Pour it into a tin vessel.

Mr. Calbreath—Won't the sulphuric acid eat the tin off?

W. L. Coggshall—It eats the dirt, not the tin. That is what cleanses it.

Preparing Bees for Winter.

"What is the best method of preparing the brood-nest for wintering?"

Mr. McEvoy—About October 1, I like to bring the bees successfully through the winter with the least consumption of stores, and that is a thing that I worked on for quite a while in my early days of bee-keeping. To do this I surround the queen with five or six combs, one on each side, and put them in a warm spell in January. There isn't the chance for them to commence much brood-rearing, but when I wintered them on a full set of combs and left an open center, and a warm spell came in January, young queens would start laying, the cluster would become broken, and spring wandering rearing-resulting in the colony into winter with sealed stores, crowded on the least number of combs, and when I haven't sealed stores to do it feed upon those are killed.

Mr. Calbreath—Beginning before October 1 to feed?

Mr. McEvoy—Sometimes before and sometimes after, and where I didn't keep them up after the nights got so cold, the bees wouldn't go up in the feeder, but by placing the feeder underneath so as to bring the food within an inch of the frames, a night in October when the ground was covered with white frost, they would go down into this and take up perhaps seven or eight pounds of wax in some nights. Whereas, if I put it above they would withdraw, and I would lose the colony by not feeding early. I like the combs all sealed. It is work, but it pays.

Mr. McEvoy—Do you begin feeding after brood-rearing has ceased?

Mr. McEvoy—Yes; and if I find that brood-rearing continues, I shut up, I give them sealed stores and shut it off in that way.

Mr. Calbreath—Won't the feeding start brood-rearing?

Mr. McEvoy—Do it so suddenly that it won't. If I do it slowly it will waste the stores, and start brood-rearing. If I can feed them up in one or two nights, I do it. The sooner you do it the better.

Mr. West—Is that for wintering outside or indoors?

Mr. McEvoy—If I have them out and in, both. Of course, in the latitude [Ontario] I am in I like outdoor wintering: but for indoors it will do equally as well.

Mr. Barb—Doesn't it make it too cold in the hive to have the bees on so few combs?

Mr. McEvoy—No, the bees are crowded on these, and when they get any honey, instead of hunting all through the hive, all they have to do is simply to lean forward.

Mr. Barb—If much far apart do you have the combs?

Mr. McEvoy—The regular distance, about 1 1/2 inches from center to center. As soon as the honey is out of them in the spring I want them ready for breeding.

E. R. Longnecker—Suppose there are combs containing brood when you begin to feed, what would you do with them?

Mr. McEvoy—At that season of the year there is very little brood; but if there be, I take the next weakest colony and put it in that.

Mr. Calbreath—I would like to ask Mr. McEvoy if doubling up two colonies, one very strong, the bees could not be left on the full set of combs with plenty of honey. Will they commence brood-rearing early in the spring without any bad results?

Mr. McEvoy—Some years I have been brought without weighing, a hundred of them would be upon the full set. I would find that I had several that was nearly solid with honey. I could not let them be weak last; but taking all in all, from year to year, I found that ten of them would not average up with ten of those that I prepared. Some of them would be just as good, but there wouldn't be an average in ten that would equal ten that I had prepared, so much so that I do not want one colony in 100 on full stores, I prefer them to be just the same.

Mr. Calbreath—I am not quite satisfied. My experience is that the colonies that are heavy with honey in the fall, without any feeding, without any attention on the part of the bee-keeper, are the colonies that have poor queens, and not a very great many young bees; and such of course would be likely to develop in the winter or the spring.

Mr. McEvoy—Sometimes I find it so, too.

Mr. Calbreath—Such colonies would be likely to make a poor showing the next year.

Mr. McEvoy—Do you winter bees outside?

Mr. Calbreath—Yes, sir.

Dr. Mason—How many frames do you put a good, fair colony on?

Mr. McEvoy—Five or six, according to the strength.
Selling Comb Honey by Case vs. Weight.

BY R. A. BURNETT & CO.

For some little time there has been an effort made to sell comb honey by the case and count of sections instead of by the pound. This method is more adapted to the requirements of our localities than the old method of selling by the pound. There is before me as I write two letters from parties desiring to sell their honey in this way; namely, so much per case of 24 sections, without reference to the actual weight of honey. This method is especially adapted to the case of the car-load shippers who are requested to name their price per pound. In reply to that letter, one of them writes:

"In reply, I will state that it is not possible to quote any honey by the pound, for the reason that the different honey-producers use different-weight cases, and it would be an endless task to arrive at the net weight of all the honey cases." The other one writes:

"In reply to your favor of the 20th inst., I beg to say that we make it a rule to sell by the case only, as selling by the pound would put a premium on the separate honey, which is not satisfactory to the dealers as the nice separated article, which is much more even in weight and less liable to injury by careless handling. We hope that selling by the case will soon come into more general use.

We hardly care to make any comment on the foregoing quotations, but merely introduce them so that the reader may know that there is more or less honey in the comb being offered for sale in this way. To say that by selling by count is more satisfactory than buying by the pound brings to our memory the old adage so often repeated, that, "It is never wise to buy a pig in the bag," for, in all probability, it is a pig, yet when the bag is removed it may not at all meet the expectations of the buyer.

It may be conceded that some, if not many, of our expert bee-manipulators get the bees to store in each section a given quantity, filling each cell with honey to the same capacity, and there is no less, than is contained in all the neighboring ones; now if this were the case generally, the use of scales might well be abandoned, but if it is with the bees longer to put 16 ounces of honey into a section than it does 12, and a correspondingly longer time to put in 12 than it would, is it not reasonable to infer that some man less scrupulous than his neighbor would manage it so that he could get a little less honey in the section, and thus a greater lot of sections filled in a given time by the bee-manipulator than by his neighbor? And as much money for the number of sections as his neighbor produced, and, having produced a fourth or a third more filled sections, he would be that much better off financially than his neighbor; and the purchaser would have that much less honey for his full money: therefore, it would be but a little time before a case of 24 so-called one-pound sections, instead of weighing from 22 to 24 pounds, as was supposed to be the case at the beginning of this method, we soon find that the case of the comb contained about 24 sections, in many instances weigh from 17 to 19 pounds.

Although this method of selling honey in any quantity has not been in vogue more than three or four years, already we find a 24-section case to weigh nearer 19 to 20 pounds than 23 to 24; yet there are some producers in a collection of a thousand cases of comb honey, whose cases weigh from 23 to 24 pounds, while others run from 17 to 19 pounds, there being no apparent difference in the grade of honey when viewed through the glass exposure, but there is, when sections are compared with one another, a noticeable difference in the thickness of the comb.

If all men were evolved up to one standard, there would be little need of checking one's accounts against another, but as many as we are, it is at this time, at the stage where we all practice deception for the sake of personal gain—a false gain to be sure, but, nevertheless, one that is daily practiced by a very great number of us—and the desire that is so prevalent to exceed our neighbor in getting the best of a bargain, constantly in mind that this method of selling honey by the case without reference to the net weight of the contents is a great temptation to a moral nature not overly strong. It would be as fair to buy our sugar and tea by the bag of 100 pounds weight as it is to sell comb honey by the case. Nut bags hold just so much in weight and it is unnecessary to weigh the goods I serve you for so much;" while it is true that since paper bags are made by machinery they vary but little in weight, yet a machine, after it has been adjusted, does the work with such accuracy, that the bag when completed, fills it with corresponding accuracy; thus the bag when complete, if properly filled, will contain almost exactly the same amount of sugar, tea or coffee. But there are some merchants who want to sell a bag of tea, coffee, or sugar for a little less than their competitors, and to enable them to do, and yet make a profit, they arrange for a bag that will hold a little less than the so-called five or ten pound bag they have previously been using, and their neighbor is using, and by this means they are able to draw those who formerly bought of their neighbor to buy their goods, for the most of us consider it necessary to buy where we can buy the cheapest.

If the price is to be the same as reasonable to abandon weighing one of the commodities we have mentioned as it would the other, for, in either case, we would be putting a temptation in the way of a weaker brother by giving him an opportunity to cheat without fear of detection. It has been said in support of buying honey by the case, that nearly all the retailers sell it by the section and not by the weight. Let us grant this to be the fact. The sections are taken out of the cases, or they are arranged in such a way that the buyer can see what he is getting; if it is sold to him as weighing a pound, and, if he doubts, he can ask to have it weighed; if the merchant refuses to do so it would be a tacit admission on his part that he was deceiving his customer.

Now, there are very few purchasers who will take that risk in order to prove the patronage of the customer would be worth much more to him than the little he could make on a section of honey; for how many of us would continue to trade with any one whom we found deliberately trying to cheat us.

We yield to the temptation to the degree of specialization against buying or selling honey in what seems to us a very primitive way, namely, of guessing at what the weights might be. When nowadays scales are cheap, and business is so closely that the guess is no longer admissible, if for no other reason than that the ill-feeling is liable to arise between the parties buying and selling, it should be dispensed with.

Our purpose in the foregoing is to call the attention of beekeepers to this subject, especially when we find that organizations of beekeepers in some instances are advocating the abandoning of weighing their honey and selling it by the case.

Cook Co. Ill.
times we must specialize. By this I mean that we must select one line of business and push that one thing. Even what a few years ago would be counted as one line of business, we find now divided into several different and special branches. One man's specialty is extracted honey, another comb, a third queen-rearing, and such division and subdivision. It is possible for one man or firm to handle successfully several lines, but to do so requires a much larger outlay of capital. The thought is, the specialist, giving his time and energy to the one thing—mastering all the details and facilitating his production or conduct of the business—is able to discount all competitors who are less well prepared. The specialist having acquired the knowledge and facilities for handling the business, adds to its volume at a very nominal additional outlay, and it is this increased volume of business handled from approximately the same basis of equipment used in the smaller business, that enables the special and extensive operators to discount the less.

It is the argument in favor of great combinations, that the multitude of small factories or businesses, when combined under one general head and management, can be run much more cheaply than when all run separately and independently. Combination gives power, and an unjust use of this power becomes oppression and extortion. The fact that combination gives a power that often is used for extortion, does not invalidate my argument, but strengthens it—there is no disputing the fact that in union there is strength. The general benefits of co-operation or combination I will not now discuss, nor the wrong use of power, which comes of combination; I have introduced the thought here because specialization and combination are things that must be considered in our business calculations. My aim in this series of articles on " Apiculture as a Business" is to get our ideas down to a business basis. The thing most of all that has prompted this discussion, is the fact that there is an epidemic bee-fever in Colorado, and very many are rushing into the business, apparently only to make financial failures.

I am going to take the proposition of one going into apiculture as a money-making procedure, calculating cost of equipment and all necessary expenditures, and analyzing the business in its details to the final outcome. This will include a consideration of locality, market conditions, ability of apiculturist, and methods to obtain results.

One of the very first and most common mistakes made by all classes, is a failure to consider the cost, final chances of success, and whether there is room and opportunity for their proposed venture. Suppose some one has a longing to embark in the business in my territory here. He thinks I am making money, and surely he is as smart as I am—if Ailkin can succeed so can he. He does not stop to think that I am already established in the business, that I have spent years of study and hundreds and hundreds of dollars in investigations, experimenting, and advertising, have built up a trade—in short, have spent years laying the foundation for a business. Few stop to consider that it is not a question simply of mere personal fitness, but of preparation and becoming fitted by practice and familiarity with the thing we are to deal with.

I note that many of these investors are paying $3 a colony for their stock to start with. They, being no judges of the condition of the stock, get good, bad and indifferent, various sized hives, ill-fitting supers, queenless colonies, foul stock—many undesirable things. In order to have a basis I shall take the $3 a-colony price, considering that this price gets regular lives and two supers to the hive. I shall also consider that 200 colonies will be all the prospective owner can handle, and that some experience has been had to enable the owner to begin with a fair foundation knowledge of the management of bees.

A 100 colonies at $3 is $1000; honey and storageroom (small) $100; smokers, knives, veils, cart or barrow, solar or other wax-extractor, saws, hammers and tools to make or repair hives, etc. $20; total investment, $1120.

A 25-pound yield from the 200 hives would give 500 pounds, but suppose a 25-pound colony, and $10,000 pounds costs in foundation, sections, and cases, $200. The bees assessed at $1 a colony and a general total tax of 25 percent is $5—a total outlay of extra for the 10,000 pounds of honey, $205. At the average price noted in article No. 2, this crop of honey being 116 cases and a fraction (we will drop the fraction) brings $15.20. Take from this the $205, 18.20 is left, and $71.80 of interest on the investment and for the apiculturist's labor and living.

Now let us run the calculations through from this same yield of half the foregoing. We have 208 cases at $2.25, or $578.80; taking this from $105 for sections, foundation cases and taxes, leaves for the labor and interest $332.60. A glance at these figures shows at once that if the owner can not handle the stock himself and alone, if for any reason he has to hire help, very little will be left of the income.

"I know many who are being called on to invest large sums of money, and what is it worth?" Let us see what it is worth. A fair increase for 200 colonies would be 100, when handled at all with a view to getting the surplus yields. I have allowed in the above estimates, a surplus of half colonies. The first cost in the flat about $1.50 each; nailed and painted, with starters in the brood-frames, the apiculturist doing the labor, the hives cost about $2.00 each. I allowed at the start $5 a colony stock purchased to begin with, but would not cost a safe price on the increase. There is a limit to all things. You do not expect to go on increasing and selling your increase to your neighbors to go into business and be your competitors; and not only competitors, but to overstock your pastures and cut out directly your yields. Even if you did sell off the increase there would soon be no market for it—you could not continue that line of policy very long. I should say that $5 a colony would be a good, big allowance for the increase.

So far, we have gone on the assumption that the original stock remains intact, no losses in winter from queenlessness or any other cause. A small annual increase is necessary to keep up the unavoidable losses it is a rare thing that will get through the winter without a few losses from queenless colonies at least. This necessitates, then, some additional capital invested in hives. If we must, in order to keep up the stock, have some extra hives for increase, our capital put into the stock was greater than any percentage of the money. We must have a really safe basis to keep up the original stock, one should have about 25 extra hives, making so much increase in them to be doubled back or substituted for the unavoidable losses.

There is still another item not yet considered. No matter whether the yield be 5,000 or 10,000 pounds, there will be of necessity a surplus of sections and foundation, for one can not turn to an exact count. The unfinished sections left over when you have cleaned up 5,000 pounds of marketable honey or any other amount, will be from 10 to 20 percent, sometimes reaching 40 or 50 percent. This represents only the section and foundation purchased or paid for. To this we must add the cost of the additional stock carried in order to cover them. If we anticipate a 10,000-pound yield, we can scarcely do less than buy and put up at least 10,000 sections, even though we do not get half of them filled. And, if one considers the work and care for the stock, investments left over becomes a necessity that all prospectively needed hives, sections, and all supplies except cases, be purchased ahead and prepared, enough to hold the biggest crop expected, for 200 colonies, keeping the rest for future use.

These extra supplies needed and carried in stock, must be added to the investment of bees, honey-house and tools. Two hundred colonies in one apiary are too many—they should be in two places. If in two yards, a horse and wagon will be needed. Without an additional stock of honey, there is no necessary money capital to be invested in a 200-colony business where $5 a colony has to be paid for the bees, at $1500. Ordinarily it is not done for less.

In the foregoing calculations we have put the figure much higher than any green hand could accomplish. I have taken it for granted that all the product was No. 1 honey, whereas...
the inexperienced would have from ½ to 1½ No. 2 and 2½
pounds. For the past ten years I put my own bees to 2½
pounds. My general average price has been, for all grades,
about $3.50 a case—8½ cents a pound. Sections, foundation
and cases cost 2 cents, or 80 cents a colony. Investment for
700 colonies and equipment being, as per previous tables,
$1,800, I allow on this 15 percent for interest, and 10 per-
cent more for wear and tear—20 percent of $1,800 is $360,
or $1.50 a colony. A 40-pound yield at $1.50 cents makes the
gross income per colony $3.50. Deduct from this the cost of
sections, foundation and cases, interest and wear and tear—
the 20 percent on capital invested—$2.30 a colony, leaves me
$1.00 a colony, 20 colonies giving me the sum of $200
for my labor and caring for them.

If this is the way it turns out with one of so large an ex-
perience, what must be the result when an inexperienced per-
son is doing the managing? There is no money in the busi-
ness here except in the hands of practical apiarists.

Larimer Co., Colo.

HONEY-RIES AND TEXAS CATTLE.

Adrian Geltz says an important but rather discouraging
thing on page 647. Can we by skilled breeding make Texas
cattle—more tough and hardy? After a long study of this
matter Nature has already done the job and finished it. Well, then,
how about bees? Has not nature for thousands of years been
developing hardiness and honey-gathering, the very qualities
we propose to breed for?

A WOODPECKER’S “BEE.”

Thanks to Prof. Cook for his verification among woodpeckers—being a muscular, biological, our judg-
ment. It’s pleasant to see how many human things we can
find duplicated among our lower down (in this case higher up)
relations. So the woodpecker does sometimes actually “make
a bee,” and invite his fellows to help him—and they go
naturally to respond, and then go back to their own work. Page 649.

EVENING PRIMROSES AS NECTAR YIELDERS.

How mysterious are the kinds of honey-flow and seasons!
Why did the evening primroses this year abound with nectar
—both in Missouri (page 652) and here in Ohio—notwith-
standing the fact that they usually do not attract bees very
much. Prize of five cents for the boy that can tell.

The Afterthought.

The “Old Reliable” seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

SELLING EXTRACTED HONEY IN PAPER SACKS.

So she thought a gallon crock went with three pounds of
honey, and inconveniently packed it full of batter! All right
to deliver her honey in a paper sack, if you tell her to put it
out into something different. And the actual storage in
forestsacks of 1,000 pounds of honey, taken from badly leak-
ing (and badly warranted) barrels is certainly worth putting
in the papers. They were second-hand flour-sacks at that;
remember. Page 639.

MIXING OF SWARMS.

Boomer’s experience, on page 633, touches one of the
standing bee-puzzles. When two swarms mix, some think it
well and some think it ill, but whatever happens, they seldom
separate. Yet when a swarm forces itself into another hive
they usually separate. Why is this thus? I rather think that
in the latter case they don’t really mix, but stand with their
toes on a line making faces at each other. The case
Boomer gives is a little unusual as to the short time No. 1
had been in possession.

FLORAL DISPLAYS ON HIVE-TOPS.

Looking at the very beautiful apiary of J. W. Tucker &
Son, on page 634, I see pots of flowers on some of the hive-
roofs. That’s not it, but the contemplation of Ananias drops
a new thought into my mind. Could we put a “wandering
dew,” or some equally rampant vine, into a big pot and make
it weigh down the cover and shade the whole establishment
at the same time? I see some objections, but maybe they
could all be surmounted. They wouldn’t blow away as easily
till plants do.

GROWING MULBERRIES FROM THE SEED.

Considering how shy of germination many similar seeds
are, it is quite a success to have mulberry seeds sown August
15, not only up but an inch high September 20. Little ex-
ence left now for not having all the young plants we think we
need. Page 647.

BUOFFT CROP REPORTS HELP SALES.

Quite interesting to see so competent authority as R. A.
Burnett & Co. adopt the opinion that the cry of “Honey
scare and high this year” scares off customers; and that the
publication of news that there has been a bountiful crop pro-
 motes sales. This is not a popular view with our brethren;
but it’s well for the Alex. Burnett & Son to let us know this
is a view that I share. Of course, yarns about an enormous overplus would not come
under the same head. I fear there are usually quite as many
trying to lie the crop down as try to lie it up. What does a liar estimate himself to be? A crook
Bull is more than a match for a dozen of Ananias Bear. Esq.
The latter can not possibly see any less than none in any given
locality. If there are five car-loads somewhere, then five car-
loads is the limit of his mendacity; while the former chap has
no limit, and can see five car-loads as a thousand. Better we
make it hot for the whole Ananias tribe. Page 643.

INDULGENCE.

The greatest lesson Christ taught the world was the bless-
edness of sacrifice. “He came not to be ministered unto,
but to minister.” “My Father worketh hitherto, and I work.”
“He that saveth his life shall lose it, but he that loseth his
life for my sake and the gospel’s shall surely find it.” He
was simply willing, but rejoiced to give himself for men.
No wonder his most devoted, and so, of course, his most effi-
cient disciple—the great Paul—could say, “I count not my
self dear unto myself.” No wonder he could rejoice in beat-
ings, shipwrecks, standing the hardest trials and most tord
soules sacrifices. He had right in sight the greater sacri-
ances of the Master, “who spake as never man spake,” who
went about doing good,” and in whose life was no guile.”
The dear Christ life and nature knew no such word as selfishness, but were guided and guided by sacrifice. No won-
der He lifted the world. No wonder He shines in lives and
hearts today. No wonder that He is to work as most blessed
leaven until the world is redeemed unto himself.

I believe that this greatest lesson is one that we keep too
little in mind in our home circles. We as parents love our
children. We love to gratify them. To minister unto them is
easiest, for our greatest pleasure comes when they are hap-
piest. Our love, unless we are wary, will trample our o
ment under foot, and will hide the teachings, the life, the
in-
comparable example of the Christ standing as a wall between
them and their application to our children. To be served,
petted, indulged, often clothes a child with the murky gar-
ment of selfishness, riches and prosperity to be, with faults,”
to work out one’s own salvation with fear and trembling,”
all these go to make character, and develop within the boy or
girl a moral and intellectual physique and stamina that will
stand him if he brace himself to the props which kindly hands so fondly place and hold in position.

I have seen many a boy, and many girls, made pulpy, in-
efficient, and, worst of all, irresponsibly selfish, by such indulgence. The finest characters I have ever known have been those who have learned independence and self-support in all their college life. Such persons can appreciate Christ’s rugged life, and, if occasion requires, can rival Paul in battling against hardships and exaltation.

My mother was very indulgent. I think she enjoyed that
I lay hat, coat or books on chair or sofa that she might have the
joy of putting them in place—of waiting on me. My first
room-mate in college had not been so treated. He was older
than I, and I justly looked up to him with great admiration
and respect. He could not have done a kinder thing to me
than he did do. He taught me right at the threshold of our
most happy, blessed and helpful association that I was to put up my things insufferable and every time. Coat on a chair; not much. Hat or books on his table; certainly not the second time, and this is saying little or nothing beside by sitting in touch with bed-leg just under the bed, as I retired; well, if so not repeated. What if it did seem a little tough then? What if it did make me dream of home and mother? It was a most valuable and much-needed assistance.

Mother marveled when I came home on vacations, at the valuable influence of college to make students more orderly and thoughtful. She did not know until I told her years after that it was my room-mate. Prof. Prentiss—long the honored Professor of Botany in Cornell University—that wrought the reform. To-day he is with God, beyond the river, but the salutary influence is still on earth, and it did much for me.

I know a mother who was left a widow with four children and a large debt. She had been a teacher: indeed, it was she that first said "college" to me, and with a look and emphasis that made me resolve that it and its invaluable gifts should be mine. She was determined that all those children should have a college education. Through indomitable energy and courage, in dint of long, hard hours of severest labor, she lifted the debts, gained a competency, and sent all her children to college. She felt that they must not have the hard life that she had suffered. She sent money to them in handfuls. One of her boys was dubbed "Vanderbilt." This was before her debt burdens were lifted, and in spite of the fact that she tried to know of his mother's trials and hardships. I begged her to withhold the money, but she was deaf to my suggestions. The older boys were almost ruined. They are now pretty successful and valuable men, but 10 years, and much more of the mother's money, to undo the mischief.

My father gave me to know that possibly he could not afford means to send me through college. "It would depend upon the expense," he said. He added something about my record. He need not have done this, as I was just asathirst for what the college could give me. As a result, I earned enough while in college more than to pay half my way, though I was far from strong. Whatever I may have thought then, I now am sure that my father was very wise. This is the first wise thing than to inculcate in his child a love for work, passion for industry, and habit of economy of both time and money. Indulgence will never grow the kind of fiber that gives us our grandest men and women. A wise requirement of work habits regularly, faithfully and promptly done, will secure noble men, and such requirement is the best heritage that any son gets from wise and loving parents.

THRIFT.

Can a father give a son wiser advice than that he save each year a part of his income? I know far more than one who spends each year the entire income of the home, for the very reason that I know of more than one whose expenses exceed the income. This course, if a man is rightly endowed with proper sensibilities, will handicap his daily efforts, as with such loss of independence comes unrest, and discontent weighs down efficiency. He that can do a wiser thing than to furnish a son or daughter with opportunity to earn money, and then watch for every opportunity to hoget a love and habit of wise saving.

LOVE OF PARENTS.

The fifth, or pivotal, commandment of all the ten, is "Honor thy father and thy mother." If Joseph, after his great honors and opportunities came to him, could have gone back to his father to buy that old, loving father; or, if there, do not seem insuperable objections to his going, then he was a bad, multitude son. If, on the other hand, his heart yearned to go, and he denied himself the great pleasure, feeling that possibly family discord and greater ill-will and discord would follow such visit, made before due preparation prepared father, and especially brothers, for it, then he was truly a grand boy. In industry, purity, kindness, and generous magnificence, he was certainly a model for all the ages.

A War Veteran's Report.

I am an old veteran soldier of the Civil War of 1861-1865, serving three years and eight months in Company H, First Michigan Light Infantry. I was injured in the service, having taken part in 15 battles, and now draw a pension; I have kept bees and farmed ever since then. I have small farms and grow fruit, wheat, corn, potatoes, and general produce. I have four colonies of Italian and hybrid bees, spring count, which have increased to 11 and yielded 50 quarts of extracted and 60 pounds of comb honey. I have had a Novice extractor for 10 years, but have not used it much, as I reduce the number of my colonies to about 10, and 12, as I have no time to attend to more. I generally sulphur that number every fall, and use castor oil obtained thus to extract from the following season.

This has been the best honey season in years in this vicinity. I have been sowing sweet clover in waste, out-of-the-way places of late years. Last year we gathered a lot of this fall, and also castor seed, to sow early in the spring of 1902. It yields lots of honey. A short 6-er bee box is very good. It has double-wall and 10-frame single-wall Simplicity hives.

Wm. Martin,

Safe Introduction of Queens.

So much has been written on introducing queens, and so much dissatisfaction and so many failures that I am hereby induced to give my plan, which, up to the present, has not failed in a single instance, and it would be of much value if some one would fall who adopts my method and strictly carries it out. If it is a queen received through the mails, I take care to examine on the quarter- cage, and I have never lost a queen by that plan, unless there happened to be two queens in the hive—not thinking that the old mother
and her daughter were together. In that
case I lose the imported queen. Now for my
never-failing plan:
First, I have a wire-cloth tent that sets over
the hive, with room for me to work under. I
place the smoker, and take the bees till them-

sections with honey by rapping on the hive,
etc., and in five to ten minutes I open the
hives and take the frame under the tent and
kill the old queen; and as I take out the
frames I set each one outside of the hive in a
box with a frame for the queen, and the
frames attached. I then shake all the bees
from each frame to the ground directly in
front of the hive, with alighting-board re-
moved, and then replace each frame in the
hive.
Understand, the old queen is now dead, the
bees are all on the ground, and the frames
back in the hive.
I now replace the alighting-board, and they
immediately start to crawl in; after about
1-4 or 1-5 of them have crawled in, I take the
queen I wish to introduce and drop her in a
cup of extracted honey, take her out and
drop her on the alighting-board near the
entrance. I then close the hive (if I failed to
do so sooner), raise a side or two of the
frames up, leaving the tent over them until they
are quiet.
I have introduced in this way at all seasons of
the year, from April to October, and have
yet to lose the first queen, and I have intro-
duced hundreds in this manner. I guar-
tantee safe introduction in every case where
the instructions are strictly carried out. If
bees are thoroughly filled with warm and
good enough smoke used to keep away prow-
ers, you can introduce a laying queen at any
time, and yet prevent any fried in introducing
virgin queens in this manner.
T. J. BAXTER.
Craven Co., N. C.

Poorest Honey Season in 15.
I have kept bees for about 15 years, and
that is the poorest season for honey in
this locality I have ever experienced. People
out West seem to think honey-dew is no
good, but we think it strictly first class,
and are always glad to see it come. Three
cheers for Prof. Cook's article on patent
medicines, on page 60, and again, Prof.
Cook.
HARRY P. GROGAN.
Scott Co., Va., Nov. 2.

Spring Dwindling and Its Cause.
I have not been in the bee business long,
and do not compare with those veteran bee-

fellows at the Buffalo convention. It seems
that the keepers all feel a spring dwindling,
and it has been the subject of much dis-

cussion by that worthy body. My experience
has been, that with proper food and all
numbers of bees flying, yet one thing
lacketh in the north, and that is a warm
summer. It seems as if winter and spring have
this section for their little ground—first one
victorious and then the other.
Bees have generally come out and
bloom by March 20, about which time a few
warm days swell the maple-buds, when the
bees rush forth, and, of course, commence
brood-rearing. This condition lasts long
enough for spring brood-rearing, when,
unfortunately, Old Winter makes a charge from
the northwest, and drives the mercury down to
10 degrees below the freezing point, holding
this position for from six to eight weeks; the
bees remain quiet for a day or two, or until
the supply of water in the hive is exhausted,
and the brood is ready to die for want of it;
then the little martyrs go forth, rain or
snow, and never return, and there you have a
genu-

ine spring failure. The same thing holds true
of the cold north and plains. The best
thing is to use packed honey. Good
combinations.

**Extracted Honey For Sale**

ALL IN 60-POUND TIN CANS.

Alfalfa Honey

This is the famous W. J. Adolm's Extracted Honey gathered in the great Alfalfa regions of Central West. It is a splendid honey, and nearly everybody who has tried it at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, sylvan Basswood blossom. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 8 cents per pound; or four or more cans, 7½ cents per pound. Basswood Honey, 50 cents per pound. Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are boxed.

**Absolutely Pure Honey**

The finest of their kinds produced in this country.

Read Dr. Miller's Testimony on Alfalfa Honey:

I've just sampled the honey you sent, and it's prime. Thank you. I feel that I'm something of a heretic, to sell several thousand pounds of honey of my own production and then buy honey of you for my own use. But however low one ought to be to the honey of his own region, there's no denying the fact that for use in any kind of hot drink, where one prefers the more wholesome honey to sugar, the very excellent quality of alfalfa honey I have received from you is better suited than the honeyes of more marbled flavor, according to many tests.

C. C. MILLER

McHenry Co., Ill.

Order the Above Honey and Then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

[GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.]

---

**Hand-Picking Drones.**

On page 651, Mr. Doolittle tells about having drones for bees to use by selling them on the comb. It is a very easy thing for Mr. Doolittle to decide just what are the best drones. It is a very hard thing for a novice. Please have Mr. Doolittle inform us how we are to decide which drones to sell, as well. ---LEARNER.

In hand-picking drones I look first for perfect development, and those under size and imperfect in any way are killed. Next I look to activity on the comb, believing those sluggish in action and motion while on the combs will be the same while on the drone. Next I look at their markings, and any varying to an unusual degree to either side of an average are disposed of. It would seem hardly necessary for me to say in conclusion, though some beginners may not know it, that drones have what are known as "buds," which means that any colony which will keep their own drones will allow the drones from other hives in the apiary to enter and be welcomed. And thus it often happens that when drones from other colonies are being driven out, you will enter the hive and pick the drones from our select, drone-reared queen, and, in hand-picking, these should be selected out and killed. This can generally be done from their color or markings. ---M. DOOLITTLE.

A Successful Wintering of Bees. This has been a very poor season for bees in my locality. We had so much rain and cold winds in the spring that the bees could work but little on apple blossoms, and when that was over it kept right on raining, so that farmers could not get many spring crops, and the farmer has been forced to get honey from the farmer as well as the bee-keeper. I sold all but about 100 colonies last spring. I increased them to 150 during the season, but got very little honey—perhaps 450 or 500 pounds—nearly all from apple clover. It rained so much that buckwheat did not yield any honey to speak of, and it has been the poorest season of the 12 that I have kept bees.

I was looking over an old diary today, where I had kept a record of my bees, of which the following is that of the past four years: Dec. 7, 1897, I had 340 colonies; Dec. 7, 1898, just as they were, with no feeding or uniting, and April 7, 1899, took out 209, losing one by smothering. Dec. 1, 1899, I put 304 colonies into winter quarters, and on March 23, 1899, took out 1898, losing one by smothering. Dec. 2, 1900, I put 130 colonies into winter quarters, and on April 7, 1900, the same number, with no loss. Nov. 17, 1900, I prepared 160 colonies for winter, and on April 12, 1901, I took out 150 colonies, one having played out through loss of the queen, I was again, and doubled up to about 100 colonies.

Now, if one who winters his bees above the ground, can show a better record than mine, I would like to hear from him. I have read the American Bee Journal for several years, and have not recognized the mention of our best beekeepers making a success.

Workers Decide as to Brood-Rearing.
A good deal of previous observation, and
close observation this fall, lead me to believe
that the ref is that queens continue laying
for a time after workers cease rearing brood
in the fall. It is a very common
thing to find eggs and sealed brood present,
but no unsealed brood.—A Straw in
Gleanings in Bee Culture.

Deep vs. Shallow Brood-Frames.
For a long time I have been on the fence—
undecided which to choose. Each kind
seemed to possess some advantages. I did
not want to give up, so I kept using half-
stories and full stories, shallow and deep (11
inches) frames in equal numbers. I can get
along very well in my home yard with the
shallow hives; but when it comes to outyards,
give me deep-frame hives, every time. In
stocking up an outfit, I am obliged to make
out the desired number partly with half-story
hives. I anticipated difficulties at the time,
and I found them when it came to managing
the hives. When two or more sectional hives
are used as one, the combs or frames of the
super section will be more or less
fastened to the lower one by bits of comb or
otherwise, making it unpleasant to separate
them; this is not the case with half-story
frames of to get through a hive just when
time is most valuable that it almost seems like
wasting it. When an empty brood chamber as a hive, the bees have a way
of boiling over as soon as opened up, which
is very annoying.
I used to think that the shallow frame
would be very nice for nuclei; but after try-
ing it for years by the side of deep frames, it
does not suit me nearly as well as the latter.
I find queens much quicker on a deep

wintering their bees above ground. My bees
were not prepared as Mr. McEver explained
to us at the Buffalo convention—they were
simply put in the bee-yard along with a full hive
of frames and honey, and tiers four high.

ANDREW M. THOMPSON.
Allegany Co., N. Y., Nov. 3.

Bee "Away Up North."
Last fall we had three fine colonies of bees,
filling two stories each, but the winter proved
too much for them. We had 4½ months
of continued cold weather there being scarcely
a day when they could leave their hives for
a flight, so when we opened them it was to find
them dead in a banana cage on the top
of hive No. 2, which we put into a new one and
made them cozy. We did not think of it
any more to give them a queen until July 6—they
looked as if they meant to stay, not losing
a single bee. I was sorry we lost so much time,
but not a great deal later I put a hole through the candy in the cage
with an awl, and waited three weeks, when I
found the queen still a prisoner. I opened the cage
and let her down with her attendants, and to
all appearances all were thankfully received.
It was interesting to see those old bees renewing
their youth and guarding their hive with
such an air of importance when the few vel-
ventures came out for a play—those bees must have been about 10 months
old. I wonder where they have gone. I think
we have given them a new funeral bed they
take themselves away; but I think
they died happy, and I am not at all sorry
that this year has been a failure, as I have
had some needed lessons and much enjoy-
ment.

I am as much interested in the bees as ever,
although I am not beyond finding one precious
colony. I am as fond of the American Bee
Journal as I am of the bees, and I do not wish
to do without either.

CINCINNATI, O.
frame, because they are not so apt to hide in the space between the lower edge of the brood-comb and the bottom of the frame. Particularly is this so with black bees, as they are inclined to run off the comb and take the queen with them. When taking a deep frame out of the hive the bee-keeper will find it enough to run off, while with a shallow one they would. I have decided to decrease my shallow-frame colonies gradually, and change back to the deep frame.—F. GREINER, in Gleannings in Bee Culture.

Raising Hives from the Ground.

Placing hives on high stands is in most places a thing of the past, and it is probable that most bee-keepers would say that there is no sufficient reason for the practice in any case. Arthur C. Miller, however, in the American Bee-keeper, seems to think there are many places where it is not advisable to set hives near the ground, and he gives a reason for his view. He says:

In my home apiary all hives are placed close to the ground; but in a small one, half a mile away, they are all on a bench some two feet above the ground. Both apiaries are covered with the same strains of bees and part of the home apiary is worked on the same system as the outyard. In the latter I have been getting comb honey, but in the home yard it is difficult and almost impossible. The production of extracted honey is also affected, but not so markedly. So far as I have been able to determine, the difference is due entirely to the elevation of the hives.

In another small apiary (six colonies) the owner has two hives about 18 inches above ground, the rest on it. The two have done finely, the others poorly. In my recently arranged with its manufactures to fill our orders. The picture shows herewith is the one we recommend for general use. It is a perfect gem of a stove for heating dining rooms, bed-rooms, and bath-rooms. It hinges back in a substantial way, and is thoroughly well made throughout. The urn removes for heating water. The brass hood, or well, has a bell, and holds nearly one gallon of kerosene oil. It is just as safe as an ordinary lamp. You wouldn't be without it for twice its cost, after once having one of these stoves. Most oil-stoves emit an offensive odor, but this one doesn't. Its height is 2½ feet, and weighs 20 pounds, or 30 pounds cradled ready for shipment, either by freight or express.

Price, f.o.b. Chicago, $6.00; or, combined with a year's subscription to the American Bee Journal—both for only $6.50. Full Directions so write for your copy.

If you want something that is really serviceable, reliable, and thoroughly comfortable, you should get this "Barler Ideal" Oil Stove, as it can easily be carried by any woman from one room to another, and thus have all the heat you want right where you want it.

Address,

GEORGE W. YORK & CO.,
Chicago, Ill.

The "Barler Ideal" Oil-Heater.

No. 4 "Barler Ideal" Oil-Heater.

Please Mention the Bee Journal when writing to Advertisers.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolster are made of German silver, and will never rust or corrode. The rivets are harden German silver wire; the linings are quite hard, the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a lifetime, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise, a message name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET KNIFE will serve as an identifying; and in case of death, your relatives will be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to get this Valuable Knife.—We send it postpaid for $1.25, or give it as a Premium to the one sending us three New Subscribers to the Bee Journal (with $3.00). We will club the Novelty Knife and the Bee Journal for one year, both for $7.00.

GEORGE W. YORK & CO.
St. Chicago, Ill.

#2 Please allow about two weeks for your knife order to be filled.

HONEYVILLE, O.

[This Cut is the Full Size of the Knife.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is made of celluloid, and its general shape is that of a beautiful gem. The blade is of fine steel, and the handle is composed of celluloid, which is transparent and durable. It is a perfect knife for any purpose.

H. M. MELBEE,
Drones of a Drone-Layer All Right.

"Are the drones from a queen who has never met a drone virilis?" is a question suggested by the editor, p. 778. Dzierzon holds that the drones of the pharaoth and the American Bee Journal, Vol. 1, the barons of Berlepsch gives a posteriori proof that is almost conclusive. On p. 778 of the same volume is given the testimony of no less an authority than Prof. Leuckart, which I think, settles the question. He says: "The origin of the drones from the eggs of uneculated or drone-producing queens are, as I have ascertained, as perfectly developed and as active as in the European species; whereas, in some cases, those are drone queens which do not actually produce them."

Dr. George W. Park, of San Francisco, Calif., has been suggested by the inquiry, and at the same time do the work more efficiently.

It is built and constructed to hatch all kinds of eggs. A hand-made catalogue containing hundreds of views illustrated with full descriptions of all kinds of incubators, mailed free. When writing address nearest office. Sure Hatch Incubator Co. Clay Centre, Neb. or Columbus, Ohio.

THE Bee-Keeper's Guide;

Or, Manual of the Apiary,

BY PROF. A. C. JOOK.

460 Pages—16th (1899) Edition—18th Thousand—$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPER'S GUIDE.

This latest and edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

For 20 NEW Subscribers.

The following offer is made to twenty subscribers only, and no premium is also given to the twenty new subscribers simply the Bee Journal for one year.

Send us TWO NEW subscribers to the Bee Journal (with $2.00, and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for $1.25, or we club it with the Bee Journal for a year—both for only $1.75, but we will give only TWO NEW subscribers to the Bee Journal for a year, and thus get the book as a premium. Let everybody try for it. WILL YOU have one?

GEORGE W. YORK & CO.,

144 & 146 Erie Street,

CHICAGO, ILL.

THE HONEY AND BEESWAX

MARKET QUOTATIONS.

Chicago, Nov. 19.—Honey is selling fairly well, and the price for the past two months, viz: choice grades of white comb honey, 14c. per pound and light (aka, amar), 13c. with darker grades, 106½c., white (aka, amar, 5½ c.), according to quality, flavor and season. Bees-wax good demand at 2½c.

R. A. BURNETT & Co.

CINCINNATI, O.

CINCINNATI, Oct. 25.—The honey market is rather dull on account of the warm weather. Extracted sells only to manufacturers from choice grades and white, for 80c. to 86c.; white clover from 80c. to 85c. Fancy white comb honey sells from 13½c. to 14c. C. H. W. WEBER.

ALBANY, N. Y., Oct. 25.—Honey in good demand and market at this is the most satisfactory time to sell. Grocers are stocking up, and will buy lines, when late they only buy enough to piece out. Fancy white comb, 15c.; mixed, 14½c.; buckwheat, 12½c. Extracted, white, 4½c.; red, 2½c.; black, 3½c. Ed. W. R. Wright.

OMAHA, Oct. 25.—New comb honey is arriving by express in small quantities from Nevada, Colorado, and selling at $3.50 per case in a retail trade in Omaha, and prices are on the verge of $3.50 to $4.00. H. R. Wright.

EVELYN BROS.

NEW YORK, Nov. 8.—Comb honey is in good demand, and there being a scarcity of stock, is becoming very dear, and has risen to six cents per pound over the usual price. Tobacco firms are in great demand, and the best in this line before Sept. 1. Our market is not consuming a great deal of extracted honey.

DETAILED TRADE REPORTS.

DETROIT, Oct. 25.—Fancy white comb honey, 16½c.; No. 1, 15½c.; No. 2, 13½c. mixed, light amber, 7c. EXTRACTED, white, 6½c.; light amber, 3½c. EXTRACTED.

M. H. HUNT & SON.

SAN FRANCISCO, Nov. 13.—White comb, 10½ cents; amber, 78½c.; dark, 60½c. Extracted, white, 5½c.; light amber, 4½c. MARKET is moderately firm at prevailing values, which remain quiet about the same as a week ago. There is considerable demand for strictly fancy in cartons; No. 1, 14½c.; No. 2, 12½c. Mixed, light amber, 7½c. EXTRACTED. BLAKE, SCOTT & LEE.

DE SUEZ, Oct. 25.—There is very little done here in new crop of honey. Some small lots of crude honey were offered on the market and selling in a retail way at $3.50 to $3.75 per case. There is very little trade at this time, the season being very dull, and the demand for dark at 5½c. Beeswax quiet at 27c. HILDEBRETH & SHEIKEN.

BOSTON, Nov. 20.—The market for honey is easing up, somewhat due in part to the busy season at which time it is much neglected. The market at this time is not so active as it was last year, due to the fact that the price was much lower and much trade in this line before Sept. 1. Our market is not consuming a great deal of extracted honey.

M. H. HUNT & SON.

DETROIT, Oct. 25.—Fancy white comb honey, 16½c.; No. 1, 15½c.; No. 2, 13½c. mixed, light amber, 7c. EXTRACTED, white, 6½c.; light amber, 3½c. EXTRACTED. MARKET is moderately firm at prevailing values, which remain quiet about the same as a week ago. There is considerable demand for strictly fancy in cartons; No. 1, 14½c.; No. 2, 12½c. Mixed, light amber, 7½c. EXTRACTED. BLAKE, SCOTT & LEE.

SAN FRANCISCO, Nov. 13.—White comb, 10½ cents; amber, 78½c.; dark, 60½c. Extracted, white, 5½c.; light amber, 4½c. MARKET is moderately firm at prevailing values, which remain quiet about the same as a week ago. There is considerable demand for strictly fancy in cartons; No. 1, 14½c.; No. 2, 12½c. Mixed, light amber, 7½c. EXTRACTED. BLAKE, SCOTT & LEE.

1901—Bee-Keepers' Supplies!

A New Bee-keeper’s Song—

“Buckwheat Cakes and Honey”

Words by EUGENE SECOR.
Music by GEORGE W. YORK.

This song was written specially for the Buffalo convention, and was sung there. It is written for organ or piano, as have been all the songs written for bee keepers. Every home should have a copy of it, as well as a copy of

“THE HUM OF THE BEES in the APPLE-TREE BLOOM”

Written by EUGENE SECOR and DR. C. C. MILLER.

Prices—Either song will be mailed for 10 cents (stamps or silver), or both for only 15 cents. Or, for 50c strictly in advance payment of a year’s subscription to the American Bee Journal, we will mail both of these songs free, if asked for.

GEORGE W. YORK & CO. 144 & 146 Erie St., CHICAGO, ILL.

Texas Bee-Keepers.

New Branch Office. 438 West Houston St., San Antonio, Texas. Rates of transportation from Medina in less than car-load lots are high, and it takes a long time for a local shipment to reach Southern Texas points.

Low Freight and Quick Delivery. San Antonio as a Shipping-point.

Our Managers. We have secured as managers Mr. Udo Toepperwein, formerly of Leon Springs, and Mr. A. Y. Walton, Jr., both of whom are well known to the bee-keepers of South and Central Texas. They are also thoroughly familiar with practical bee-keeping and all matters associated with it, and any orders sent to this branch will receive prompt, careful attention.

Our Goods. As usual our motto is to furnish the best goods of the most approved pattern. We do not undertake to compete in price with all manufacturers. Bee-keepers have learned that it does not pay to buy cheap supplies, for a saving of 10 cents on the first cost of a hive may be a loss of many times this amount by getting poorly made and ill-fitting material. Every year brings us many proofs that our policy of the “best goods” is a correct one.

Our Catalog. Very few changes in prices will be made in our new catalog, so do not delay your order, but send it at once. You will be allowed a refund if lower prices are made, and in case of higher prices ruling in the new catalog, if any, you will secure the benefit by ordering now. Catalog and estimates may be had by applying to the address given below.

Our Invitation. Whenever you visit San Antonio you are invited to call at our office and make it your headquarters. Here you will find a display of Apiarian Supplies not equaled elsewhere in Texas. You will also find on file the leading bee-journals to pass pleasantly your leisure time.

Spanish Catalog. Some of you may read Spanish, or have a bee-keeping friend who does. If so, call for our Spanish catalog. It’s sent free.

The Fence or the Ambulance—Which?

BY JOSEPH MALINS.

"Twas a dangerous cliff, as they freely confessed,
Though to walk near its crest was so pleasant;
But over its terrible edge there had slipped
A duke, and full many a peasant;
So the people said something would have to be done;
But their projects did not at all tally,
Some said, "Put a fence round the edge of the cliff;"
Some, "An ambulance down in the valley."

But the cry for the ambulance carried the day,
For it spread through the neighboring city;
A fence may be useful or not, it is true,
But each heart became brimful of pity
For those who slipped over that dangerous cliff;
And the dwellers in highway and alley
Gave pounds or gave pence—not to put up a fence,
But an ambulance down in the valley.

"For the cliff's all right, If you're careful," they said;
"And if folks even slip and are dropping,
It isn't the slipping that hurts them so much
As the shock down below—when they're stopping;"
So day after day, as these mishaps occurred,
Quick forth would these rescuers sally,
To pick up the victims who fell off the cliff,
With their ambulance down in the valley.

Then an old sage remarked, "It's a marvel to me
That people give far more attention
To repairing results than to stopping the cause.
When they'd much better aim at prevention,
Let us stop at its source all this mischief,"
cried he.

"Come, neighbors and friends, let us rally—
If the cliff we will fence we might almost dispense
With the ambulance down in the valley."

"Oh, he's a fanatic," the others rejoined;
"Dispense with the ambulance! Never!
He'd dispense with all charities, too, if he could:
No, no! We'll support them forever;
Aren't we picking folks up just as fast as they fall?
And shall this man dictate to us! Shall be?
Why should people of sense stop to put up a fence
While their ambulance works in the valley?"

But a sensible few, who are practical, too,
Will not bear with such nonsense much longer;
They believe that prevention is better than cure,
And their number will soon be the stronger.
Encourage them, then, with your purse, voice, and pen.
And (while other philanthropists daily)
They will scorn all pretense, and put a stout fence
On the cliff that hangs over the valley.

Better guide well the young than reclaim them when old,
For the voice of true wisdom is calling:
"To rescue the fallen is good, but 'tis best
To prevent other people from falling."
Better close up the source of temptation and crime
Than deliver from dungeon or galley.
Better put a strong fence round the top of the cliff,
Than an ambulance down in the valley! —Selected.
The "Barler Ideal" Oil-Heater

Saves Its Cost Every Year!
NO ODOR! NO SMOKE! NO ASHES!
Costs only a cent an hour to run it.

The editors of The American Bee Journal are using the "Barler Ideal" Oil Heater, and it is all right in every way. We liked it so well that we wanted our readers to have it too, so we have recently arranged with its manufacturers to sell our orders. The picture shown here is the one we recommend for general use. It is a perfect gem of a stove for heating dining-rooms, bed-rooms, and bath-rooms. It hinges back in a substantial way, and is thoroughly well made throughout. The urn removes for heating water. The brass fount, or well, has a bail, and holds nearly one gallon of kerosene oil. It is just as safe as an ordinary lamp. You wouldn't be without it for twice its cost, after once having one of these stoves. Most oil-stoves emit an offensive odor, but this one doesn't. Its height is 25.5 feet, and weighs 20 pounds, or 30 pounds crated ready for shipment, either by freight or express.

Price: Chicago, $8.50; or, combined with a year's subscription to The American Bee Journal——both for only $8.50. FULL DIRECTIONS GO WITH EACH STOVE.

If you want something that is really serviceable, reliable, and thoroughly comfortable, you should get this "Barler Ideal" Oil Stove, as it can easily be carried by a woman from one room to another, and thus have all the heat you want right where you want it.

Address, GEORGE W. YORK & CO.,
Chicago, Ill.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

HOWARD M. MELBEE,
HONEYVILLE, O.

(THE CUT IS THE FULL SIZE OF THE KNIFE.)

Your Name on the Knife—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as true-perfect as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a lifetime, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelties" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are fortunate enough to have one of the "Novelties," the Pocket-Knife will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side? The accompanying cut gives a false idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelties" must be seen to be appreciated.

How to Get this Valuable Knife.——We send it postpaid for $1.25, or give it as a Premium to the one sending us three new subscribers to the Bee Journal (with $0.10). We will club the Novelty Knife and the Bee Journal for one year, both for $3.00.

GEORGE W. YORK & CO.
St., Chicago, Ill.

#*Please allow two weeks for your knife order to be filled.

Please Mention the Bee Journal when writing Advertisers.
The Cry of Adulterated Honey, heard lately in Chicago, is bound to interfere somewhat with the sales of the pure article. The Daily Tribune, of this city, had the following in regard to this subject, in its issue of Nov. 15, introduced by a heading in large type, "Law Stops Bogus Honey!"

Glucose honey, under the attractive guise of "pure clover honey," is invading the Chicago markets to such an extent that the efforts of the bee-keeping and associated interests are directed toward investigations of this imposition. One entire carload of "honey," consigned to Dr. Dawson, of the Western Brokerage Co., 42 River street, from a California firm, was barred from the markets yesterday except as a plainly labeled adulteration.

The analysis of the "honey" composing the consignment showed that it contained from 60 to 60 percent of glucose, and honey, the stuff was condemned. The concern had the choice of selling it as a glucose mixture or of sending it back, and he chose the latter course, at the same time canceling other orders which would have brought other large quantities of the glucose honey into Chicago.

*Editorial.*

Unlike many of the adulterations which flood the market, the glucose honey is not regarded as an injurious mixture, and the Pure Food Commissioners affirm that the imposition on the purchaser is one which injures his pocket-book and not his health. The dealer has the right to sell the "honey" under the label of glucose mixture, and as such, it is worth about one-fifth as much as real honey.

One complainant, Dr. A. J. Park, 520 East Fiftieth street, said:

"I know of no place in Chicago where one can purchase a pound of pure honey. I called the attention of my grocer to the fact that his tin cases of "white clover honey" was manufactured stuff made up of glucose and paraffine. He at once called on his South Water street merchant and demanded that his money be refunded, or that the merchant disclose the name and place of the party from whom he got the mixture, but he declined."

Almost exasperating to one who is at all acquainted with the honey business to read such a paragraph as that. Of course, every doctor ought not to be supposed to know everything, and so Dr. Park perhaps should not be blamed for not knowing where in all Chicago he could get a pound of pure honey. But there are tens upon tens of absolutely pure honey in Chicago at almost any time of the year. I can take the innocent Doctor to see seven samples of the genuine article any time he will accompany me.

Dr. Park also conveys the idea that there is such a thing as manufactured comb honey—the comb made of paraffine and filled with glucose. I want to say that the Doctor has not an excellent opportunity to get a larger single fee than he ever has received, nor will likely ever receive in the future if his medical knowledge is on a par with his information about pure honey. There has been an offer of $1000 standing, but unclaimed, for 20 years, to any one who would find and present a single pound of comb honey which bees had no part in manufacturing. That offer is open yet, and I will personally guarantee that it is bona fide, or will make a similar offer. Now, gentlemen, either present that pound of manufactured comb honey, or for ever after hold your peace about it.

It is very unfortunate that the daily press does not seek its information concerning such matters from those who are in a position to know. It certainly would not go to a blacksmith to learn of the production of steel; then why should it accept the dictum of those who don't know a bee from honycomb, when they desire information on honey-production?

I do not believe that The Tribune would willingly injure any honest industry, but in publishing such matters as I have referred to, and also the cartoon on "How doth the little busy bee 's" in the Numeral that is appearing before its readers untruths, and at the same time doing untold injury to the producers of genuine honey throughout the whole country. Yours very truly,

George W. York,
Editor 'American Bee-Journal.'
SAVS MUCH HONEY IS PURE.

EDITOR OF THE AMERICAN BEE JOURNAL TAKES EXCEPTION TO STORIES OF LIQUIDATION.

That the bee-keepers as a class are opposed to the adulteration of honey is averred by George W. York, who, as editor of the American Bee Journal, is in touch with the industry. Mr. York declares that there is plenty of pure honey on sale in Chicago, and takes exception to the statements which have been made by men who are supposed to know something about pure food. In a letter to The Tribune:

"The bee-keepers have done in their power to aid not only the enactment but the actual enforcement of the laws intended to prohibit the adulteration of honey, or compelling the mixers of the countless article to label it according to its exact ingredients. In an interview Mr. Jones, the Pure Food Commissioner of Illinois, is made to say: "The California honey has a brown coloring around the cells. True honey is perfectly white. The purchaser can detect the fraud by this simple rule."

"This would be important if it were true. Unfortunately, or fortunately, there is no truth in the statement. Genuine honey is perfectly white in appearance; and, second, there is no glucose comb honey produced."

"The carload of honey referred to in the first quotation from The Tribune, is extracted honey in tin cans. We looked it up at both the offices of the Pure Food Commission and the Western Brokerage Co., and found that the labelers of the former discovered about 25 percent glucose in the sample submitted to them by the Western Brokerage Co., the latter firm having become suspicious of the honey. After hearing the result of the analysis, they reported it to the California firm from whom they bought it, (in Oakland, we believe), and were holding them accountable for the adulteration of the California firm, it being still in the car. We understand that the California firm declare it is pure honey, and that their representative is coming on to Chicago to prove it. He will likely have a hard job of it—if he comes.

"We believe The Tribune, in publishing the statements credited to Dr. Park and Commissioners, are more dangerous to pure honey than can reasonably be imagined. Because of pure honey than it can remedy in a long, long time to come. Also, the dearth of a dozen things, which pretends to illustrate how so-called "comb honey" is manufactured, is another unfortunate thing. Already, we hear that Chicago grocers are feeling the full effects of the misleading reports and misstatements published by The Tribune, and their honey sales are diminishing accordingly. One dealer said that the falling off in the sales of pure honey would be at least 25 percent. While all lovers of truth and right will appreciate the slight correction which The Tribune published a few days later, it could hardly have done less, in justice to the honest people and industry which it misrepresented, to have been "fit to print as we wrote it for publication."

"It is exceedingly unfortunate that newspapers do not apply to those who are in a position to know the facts concerning technical matters. With all the bee-keepers living in the city, and on the great lines of daily access, there need never be anything misleading, or the least bit untrue, given in the public press concerning the manufacturers of honey or honey production. But it would not be quite so discouraging if, when an error has been published, the truth was brought in close touch with the public, so that it was corrected, so that the injustice could be rectified as nearly as possible.

"Let us hope that more care may be exercised hereafter on the part of those who think they must write or speak on subjects which they are wholly unfamiliar.

CREATING A DEMAND FOR HONEY.

"How can a demand for honey be developed in a city where at present there is little or none consumed?"

Mr. Niver—I have been for six months now working up a demand for honey in my city, and I have had house-to-house canvassing, and I must say that I am delighted with my success, by going direct to the family, sitting down and telling them what we get it from the bee-keepers, and taking along some foundation, and so on. Getting them interested in the bee-talk, I can sell them, perhaps, a pound or two of honey, and in about a month I go around again. I have found that there is a demand worked up that way which grows along with its growth.

"I find that the third or fourth time I find that the demand is not diminished, but increased. People do not know that honey is the cheapest sauce that can be bought—I mean, the sauce of the hive. Everything is very high in the line of sauce. Fruits are very high, and the working people feel that very severely. Now we are having boom times, and the most prosperous times known to this country, and the hardest times for a man to support his family on his wages that I have ever seen. By going direct to the people themselves, and teaching them about extracted honey, not comb—they look on comb honey as a luxury beyond their pocket. I have tried this method in six months, and have sold two or three different towns worked up. I find that the trade is growing in most towns, and in a little while we will get so that we can get out our bulk honey into the grocers. We can not do it now. You can not sell honey in a bottle, with a nice label on it, for 25 cents a pound. You have to offer it at reasonable rates by the pound, and then you can sell it.

"Mr. Cook—How many of those lectures could you give a day?

"Mr. Niver—I don't know; I talk several hours a day.

Mr. McEvoy—What size of samples do you show them?

"Mr. Niver—My method is to take along the honey in 10-pound cans. I go into the house with a quart milk-bottle and a teaspoon inside of it, and ask for a small dish to put some honey in; and in get them all in there eating honey, and I make them use their own spoons. While they are doing this I am explaining. After that I have been selling 8 pounds for a dollar, for fine white honey. The great majority of people get paid once a month; if you go just after payday you can sell a great deal of honey, like you can before."

H. C. Ahlers—Would you kindly give us figures of what you could sell in a day in that way?

"Mr. Niver—I have sold 300 pounds in a day, and he has sold as low as 35 pounds in a day.

Mr. Ahlers—I sold a thousand pounds in two days in 3 lb. Mason jars and 13 lb. pails; ten cents a lb. straight. If a grocer wants my honey it is worth 10 cents a lb. I sell to private families for strictly cash, in Milwaukee and vicinity. I weigh in the pail. The collection year is 1895 to 1898. I bought 21,000 pounds of honey, and I weigh the pail in. This gives me about 9 7/10 to 10 cents for the pail. I lose about 13/2 cents on the pail. I sell the honey 20 cents a pound at a jar. I go to private families and keep a record of them. I know where I am going when I start. I take a thousand pounds along, and make the trip in three days. I sold 8,000 pounds in six trips, 2,000 pounds around home. I sold my own crop of 6,000 pounds, gathered from 37 colonies, and bought 2,000 lbs. Mr. Howen—I feel sorry for a bee-keeper who produces honey and can't sell it. I can't produce enough to fill my orders.

H. J. Fuller—For the benefit of comb-honey men, I wish to say a word or two. I retail comb honey, and I retail from 100 to 300 lbs. a day in small towns in Cattaraugus County, I take it from house to house, the same as these gentlemen retail their extracted honey. I am getting 15 cents a lb. for No. 1 honey, and for dark honey all the way I can get 12 cents, according to the quality. I sell on Tuesdays. Our pay-day is Monday, and I want to go when they have money.

W. L. Coggshall—The wholesale price is retail; no trouble to sell that way.

"Mr. Niver—I have heard a good deal said on what package we shall put our honey in, but I have got so that I believe I don't want any package at all. I prefer every time to have the lady produce her own package. She is sure it is clean, then.

Mr. Ahlers—Well, people offer me a package and they offer me butter-crocks. I live about 28 miles from Milwaukee. I would have to haul their butter-crocks. I allow them 10 cents a mile.

Mr. Tyrell—I would like to ask Mr. Niver what argument he uses to answer the question why extracted honey is cheaper than comb honey.

"Mr. Niver—By showing the picture of the extractor and telling them that the bees build the comb only once, and we put it back and they fill it up again.

Mr. McEvoy—I think if every State in the Union, and Canada, had some one going around in that way, talking to people, it would be a good thing.

Huber Root—For the past two
months I have been seeing a great
many people at the Pan-American
Exposition, and I find eight out of ten
of them imagine we mash the comb up
and sell the honey out through a
cheese-cloth: they know absolutely
nothing about bees, or anything about
the way extracted honey is secured.
Mr. Vinal—I think it is a good plan,
but I can't teach me how to make a
man as Mr. Coggsall is able to hire.
Mr. Tyrrell—It is true that not all
of us are salemen. The majority
of people who produce honey are not ca-
able to sell their own honey by a
house-to-house trade where we have to take
up the time to explain how the honey
is produced and why it is cheaper.
The plan that I used was to put my
honey in suitable packages, then tak-
ing a circular which was just as
brief as possible, explaining how the honey
was produced—I would use say quart
boxes, and on each box I would put a
circular, together with another small circular
telling the people why I left it
in this way. Ninety-nine out of
100 people would not step to the door,
and hear you have something to sell,
say "No," I leave the package of
honey and the circular, take the number
of them, and in a few days I will call
again on a certain day, and pass on.
Then I would go over the same ter-
ritory a second time, and I found that if
I left it long enough—perhaps a week
—if they were honey users, they had
handed the honey, found it was good,
and would pay for it.
Mr. Longnecker—I would like to ask
Mr. Vinal if he will try to sell a
package of honey at one time,
and when he came again in a
week and the honey hadn't been used
and they didn't want it.
Mr. Vinal—I found there was only
one place where anything like that
ever occurred, and that was at the
house of a lady where the honey had
decreased perhaps an inch, and she
didn't want it over the top! That
is the exception.
Duo Toeppeiner—Do you label all
your honey?
Mr. Vinal—Yes, sir, telling where
it is produced.
Mr. Toeppeiner—We label all our
first-class honey, and get the groceries
to sell it, and after the people get to
use it they will buy more, and then
Mr. Vinal—I have had a little expe-
rience in selling comb honey, and
my plan has been to put the honey in show-
cases, properly labeled, and place it
in the stores on the commission plan, and
let them sell it at retail. I get 25 cents
for it retail, and 20 cents at the stores.
Selling Honey Through the Stores.
"Would you sell honey through the
stores?"
Mr. Mason—I think that has been
answered already.
Mr. Toeppeiner—If a person has
plenty of time, I think they would do
better to retail it.
Mr. Vinal—I couldn't take it to the
groceries, for this reason: I don't
want groceries enough to pay for what
honey I have. I would rather have
some one handle it for me, and
men in my section want me to take
trade. If I want any trade I have
no objection to selling one or two
cases of honey, but where
I have the money, and don't want trade, then
I retail it and get the money for it.
Mr. Niver—I would like to ask at
what price he sells to the grocer.
Mr. Fuller—The same price—15 cents
a pound.
Mr. Niver—And what do they sell it
for?
Mr. Fuller—They make it profit
on the goods they give me.
Mr. Niver—I have been a groc-
ery-man for many years and you couldn't
trade it to me for 20 cents a pound.
Mr. Fuller—You talk about the price
of honey. I will buy 500 lbs. of comb
honey at 13 or 15 a cent a lb. delivered
at my place, for my trade at the
stores. I would pay 15 cents a
pound for 500 lbs. I can not get it in
Boston.
Mr. Fuller—I would like to ask one
more question of these gentlemen who
sell their honey in the cities, whether
they buy from the beekeepers.
Mr. Vinal—Sometimes, but
whether they have to obtain
a license to do their work, or whether
they go on without being molested
by anybody.
Mr. Ahlers—I am a beekeeper, and
I have a right, at least in Wisconsin,
to sell my own produce. Now, I don't
know if I have a right to buy the honey
and sell it, but those questions are
never asked. I have sold it to several
police men, who never asked me any
questions, and I think there will be no
trouble at all.
Mr. Granger—I have noticed one
difficulty about retailing honey, and
that is, there are so many beekeepers
who sell for the same price at retail as
at wholesale. In the district where I
live there are quite a few beekeepers in
a small way, and they generally run out
of all the honey they have for sale, and
then there is the trouble, and find they
cannot: it is all being sold at the
same price, 1 lb. or 100 lbs. When
I have sold out what little I have, and
you can't get more at wholesale, I
cannot get it.
Mr. Miller—With us we have to pro-
tect the groceries. If I sell honey
at 10 cents retail I must cut out to the
grocery store, and I always protect them by
that means. I still sell at retail, as
much as possible, and at the present
time I am getting 11 cents for my
extracted honey, including the tins.
Are Queens Injured in Mailing?
"Does it injure queens to send them
by mail?"
Mr. Mason—Yes.
Mr. Benton No. It does injure
them if they are improperly packed; if
well packed it does not, I believe.
Mr. Mason—I would agree with him,
but I warn any one well packed.
Mr. Rankin—I think the danger
to queens sent through the mail is about
as great as that of a person traveling
on a railroad, provided the bees are
properly packed.
Fred Schmidt—Do you think they
are properly handled today, the way
they are thrown out and kicked around?
I do not.
Huber Root—I think the trouble is in
the confinement in passage through
the mail, and not particularly from the
route handling. A beekeeper was asked
when she is laying well and shut her
up for several days, and keep her right
in the hive and she will not do so well after
it.
W. L. Lathrop—Take queens and
cage them properly, pack them, keep
them a week, then liberate them and
see if you can notice a difference. I have
tried quite a few good many experi-
ments. I was led to it from buying
queens. My experience is that they
do not lay so regularly. The combs
will not fill so well. They are more
"skippers," and she will begin to fail
sooner.
Mr. Benton—I receive a great many
queens from different countries, and
often as far as the Island of Cyprus,
and those queens were well packed.
I prepared the cages myself, sent them
there and gave careful instructions as
to how the beekeeper was to put them
in, and in no instance have I been
able to perceive that those queens that
had been from 14 to 20 days in the mail
sacks and traveled 6,000 miles, had been
injured by that journey.
Mr. Gemmill—Aside from the pack-
ing don't you think that the caging of
a queen a few days before she is ship-
ped is a great mistake, how do
with the safe delivery of the
queen?
Mr. Benton—I don't practice that.
One point has been brought up, that of
throwing the mail-sacks from the train.
In some places here and there, a queen
was to be thrown from the train I enclosed
the cage in a cloth-lined envelope,
which would tend to protect the cage in case of
lock.
Mr. Fuller—What kind of a cage do
you ship in?
Mr. Benton—It is a small, wooden
cage, with three corners and a back
which I invented some years ago. One
end has the food compartment; the
center compartment is a dark chamber
with only indirect ventilation; at the
other end is the queen, and is provided
with one box. You can buy it.
Mr. Fuller—How many bees do you
place in there as an accompaniment?
Mr. Benton—From 10 to 20, accord-
ing to the time of the journey.
Mr. Mason—One of two things is
certain: The queens are injured in
the mail, or else the queen-breeders
send out poor queens. I have paid as
high as $8.00 for a queen and I would
rather pay eight cents for it, a finally
and I sell 200 queens. Every last one of them—except one I
got last year—proved to be poor.
Mr. Cook—There are hundreds of
testimonies that they are good and
they do produce a good copious bees.
Mr. Mason—Yes, sir, I can give you
one good one out of eight.
Mrs. Acklin—We not only send out
queens through the mail, but we get
in queens, and I will state to you that
we get only what is not all right.
Bees Moving Eggs.
"Do bees move eggs from one cell to
another?"
Mrs. Acklin—I think they do.
I think they move an egg occasionally
from one hive to another.
MATING OF QUEENS.

"In queen-rearing, are the evils of in-breeding greater to mate father and daughter, or sister and brother?"

Dr. Miller—You are asking a question about which is the worse of two things, either of which is impossible. You can not mate father and daughter, because the father is dead before any of his children are born. You can not mate sister and brother, for the drone has no sister except his mother. In this matter of breeding it is a matter of close blood you are considering, and whatever you may call them the queen is the daughter of her mother, and also the mother of the drone with which the mother mated, but the drone is the son of his mother. Now if you say he has any father, it must be his grand-father. He has precisely the same blood as his mother. So when you are considering breeding in cattle the nearest that you can have is between brothers. And this near blood in this case is between the drone and his mother, so that if you take it in the sense that you are talking about other animals, the drone is the brother of his mother.

RED CLOVER QUEENS.

"Are the progeny of what are advertised as red clover queens better honey producers than the progeny of queens reared by other queen-breeders?"

Mr. Greiner—I notice that all queen-breeders today advertise the red clover queens; none have others.

LONG-TONGUED BEES.

"Are long-tongued bees desirable?"

Mr. Howe—As I sent Mr. Root a bee a while ago, and he sent me back word that she had as long a tongue as any he had measured that year, I would like to tell you the difference between that colony and common colonies. These bees with long tongues gathered honey when my black bees were starving to death. The black bees were really starving, and these bees weren't robbing.

SPELLING REFORM.

"Is reform spelling desirable in bee-keeping?"

Dr. Mason—Yes.

Mr. Ahlers—No.

Dr. Mason—Desirable everywhere.

SELECTING A HOME BEFORE SWARMING.

"Do bees ever select a home before swarming?"

Dr. Miller—Yes.

Mr. Calibraco—Sometimes, not always.

MATING WITH AN IMPURE DRONE.

"Does a pure-blooded queen become contaminated by mating with an impure drone, so that her drone progeny was impure?"

Mr. Cook—No.

Mr. Benton—I don't think she does, practically. There are some very curious effects, but it seems to me that the question is open to a slight dispute. That is as far as I would go in it.

Dr. Mason—Now, the queen mates with the drone and secures what seminal fluid she wants for life, does she not?

Mr. Benton—Supposed to.

Dr. Mason—Can she keep up that supply without renewing it in any way, so as to fertilize the thousands upon thousands of eggs that she lays?

Mr. Benton—I should suppose she might keep up that supply during a fairly long life, but, as we well know, that supply is sooner or later exhausted, and the queen is utterly exhausted and lays drone-eggs.

Dr. Mason—Then she doesn't in any way add to the supply of that seminal fluid from herself—no growth of it at all?

Mr. Benton—No, I don't think that is possible.

Dr. Mason—Then, if that is not possible, the progeny can not become contaminated in any way?

Mr. Benton—Except by the possibility of her having mated the second time.

Dr. Mason—Mr. Doolittle thinks that the queen does in some way add to her supply of the seminal fluid, so that she can keep that up; if she does, then may she not be making that impure?

Mr. Benton—I don't think impurity comes in that way. It is the presence in the system of this foreign substance a derivation from the male bee—which contaminates the blood of the queen and by that the drones.

Dr. Mason—Now, will it do it?

Mr. Benton—That is the question that is unsettled.

BEE SPACE OVER BROOD-FRAMES.

"Why should the top-bar of the brood-frame of the Langstroth hive be below the top of the edge of the hive instead of on the top of the frame? Is there any advantage in having the bee-space on top of the frames in the brood-chamber, or under the frames, and have the bee-space on the under side of the super?"

D. H. Coggshall—In extracting honey it is very essential to have a bee-space on top.

Dr. Mason—There certainly is an advantage in having the bee-space on top instead of the bottom. If there is no bee-space on the bottom, and you set the hives for any time on the top of the frames, you are liable to crush them. In my hives I have the top of the frame even with the top of the hive.

John Fixter—We have both above and below, and I wouldn't have a hive in the yard that didn't have a bee-space above.

Mr. Betsinger—No hive is perfect by omitting a bee-space on top of the frames. If the space is omitted on top of the frames, and the same is added under the frames, there you use the two in connection, and when the season is good, and they are somewhat crowded, they will place burr-combs between the lower frames and the frames above. Now, in removing those frames, if the bee-space is underneath the hive—not on top—then these burr-combs adhere to the ends. If the bee-space is omitted on top of the brood-chamber, and is put in the super, you are living under the same disadvantage—as you change supers from one hive to another those burr-combs must be removed.

The convention then adjourned until 1:30 p. m.

THURSDAY AFTERNOON.

The convention was called to order by Pres. Root.

CHANGES IN THE CONSTITUTION.

Mr. Abbott—I have a matter I would like to present, and that is, I do so, I would like to tell the members of this Association something that I think they ought to know. This room is occupied by the janitor who looks after it said that you had been the cleanest set of people that he ever had anything to do with: that you didn't smoke, or chew, or make the room worse, and that you ought to know it. You can see that it pays to be decent. I have here a recommendation of the Board of Directors which the directors present at this meeting recommend the following amendment to the constitution: "Art. IV., Sec. 1, to be changed reads as follows: 'The officers of this Association shall be a General Manager, a President, a Vice-President, a Secretary, and a Board of twelve directors, whose term of office shall be for four years, and their successors are elected and qualify, except as provided in Sec. 2 of this article.' Now, the change in that Article is this: The present Board of Directors shall consist of the General Manager and twelve directors, making the General Manager a member of the Board of Directors. Now, another reason why this change is that the General Manager is an employee of the Board of Directors, and we want to make it so that the Board of Directors, the members of the Board, and the General Manager a chance to do what they are empowered to do in the next Article, which I will read.

Dr. Mason—That simply provides for removing the General Manager from the position of a Director.

Mr. Abbott—That is all. He continues as secretary of the Board and as general manager. Of course a Sec. of Art. V., add the following: 'And said Board of Directors shall have power to remove from office the General Manager for cause, and fill the vacancy until the next annual election.' Now, this amendment has no reference to the General Manager. It provides for a contingency that might arise. It gives the Board power to say to him, 'We don't like this way of doing, and we will simply remove you until the next election. And then the members can elect a General Manager just as you have been electing him.'

Moved by Dr. Mason, and seconded by Mr. Benton, that the convention endorse the recommendations made by the Board of Directors, Carried.

CARNiolAN HIVE-ENDS, ETC.

Mr. Benton then exhibited some front ends of Carniolan hives which he stated he had been in use many years. He pointed out how the effect of the bees clustering in front of them, they making no impression on the board where it was painted, showed that they were in front of very smooth surfaces, such as the smooth surface of fruit. He further said: These hives open at the rear end, and in Carniola their plan is to feed hives in winter and stimulate until the time for warming comes, and get them in condition for the buckwheat harvest. Probably
19-20 of the bees in Carniolia are in boxhives.

Mr. McEvoy—How is the yield of honey?

Mr. Benton—Very good, indeed. Tho' we have only 2 acres of buckwheat. In extracting the honey, they first put it in a sack, comb and all, and then subject it to great pressure. Of course, it is 'strained' honey, and contains some colour and minerals of a green. It is excellent beer-footh, though. It stimulates brood-rearing more rapidly than the feeding of sugar.

Mr. McEvoy—And how were they to save their bees, the country would have none many?

Mr. Benton—I don't think they would. They take out their weakest colonies. Foul-broody colonies are almost sure to be taken out.

Mr. McEvoy—What are their winters like?

Mr. Benton—Very long and severe. I saw the mercury once 20 degrees below zero, and very deep snow in most places. We obtained from it, a year or two ago, in one to ten thousand feet above the sea level. It is quite cold in October, and very cold in November, and it lasts until March and April, with very long, cold spring, following away into May. The percentage of loss of bees in the winter is quite small, and spring dwindling is a thing almost unknown. The winds sometimes change very suddenly, bringing a thick fog down into the valleys, and thousands of the flying bees are killed. Only understanding that, the colonies are so prolific that they revive very quickly. During the buckwheat season the harvesting of honey occurs. I have sometimes seen all of the working force of a colony wiped away in a single hour, and thereby the hope of any future yield of surplus honey during that harvest was entirely precluded. (Continued next week.)

Contributed Articles.

Gathering Not in Proportion to Length of Tongue.

By G. M. DOOLITTLE.

During the spring and early summer of 1901 quite a little was written regarding the high gathering qualities of bees having long tongues, and many advertisements were inserted in our bee-papers, holding out inducements to purchase bees having long tongues, while bees having such were the ones which secured the greatest yields of honey; and especially so in districts where the red clover was grown by the farmer for hay and pasturage for his flocks.

At that time I did not dream that I should have any chance to prove myself of the correctness of this long-tongue matter, for nearly a score of years had elapsed since red clover bloomed or gave seed in these parts, owing to a very small amount of rainfall. And I thought in the annual clover just before the blossoms were to open, causing the blossoms, while in the bud, to burst, so that not one bud in a million came to perfection. But the past season, from some cause or other, the nectar seemed to be absent, and before I was hardly aware of it, my eyes beheld hundreds of acres becoming red with the bloom of red clover.

And at about the same time the weather became hot and favorable for honey-secretion, so that by June 20 we had a yield of honey on, according to what that I had ever known at that time of the year. In fact, the flow of nectar was nearly, if not quite, as great as any I had ever known from basswood when at its best, except that the nectar is always thinner from clover than from basswood. And this flow of nectar of clover, as it continued, in varying degree, clear through the basswood yield and up to August 1, thus helping greatly to finish up and complete nearly all the part finished sections, remaining at the close of the basswood bloom. As a result, I obtained (together with what was secured from buckwheat, which gave only a light flow) the largest average yield, from colonies not robbed for the bees, of any ever obtained in the 52 years I have kept bees, namely: an average of 176 pounds of section honey per colony at the ant-apar, and 180 pounds by the hand in the hay yard.

In the hay yard I had two colonies close to each other, one being headed by a queen from my original honey-gathering stock, and the other by a very fine-looking queen procured by way of exchange during 1901, from a breeder in Iowa. These colonies were as nearly alike as to outward appearances in early spring as two peas, but as the season advanced the brood in the colony having the Iowa queen outstripped that from the other by thousands of cells. Till I began to think I had a prize in this new queen; but when the season closed I found that I had from the colony headed by the queen of my rearing, 201 completed one-pound sections, 21 partly filled, and 134 pounds of honey; whereas the Iowa queen gave only 44 poorly filled sections, none partly filled, and had only 12 pounds in the hive October 1, so that they had to be fed 13 pounds for wintering.

Remembering that I had seen somewhere in the bee-papers that if we would be fair in testing this long-tongue matter, bees from the colony giving the poorest yield of honey should be sent as well as those from the one giving the greatest yield, I thought myself to send a dozen of these bees, (from each colony) to Prof. Gillette, of the Colorado Agricultural College, as he had asked for bees to measure, through the columns of the American Bee Journal, and I accordingly did so. When Mr. Gillette reported he gave as the average of "Lot 1" (from my queen) 25.1, and of "Lot 2" (from the Iowa queen) 25.8, the same being in hundreds of an inch. So it will be seen that the colony giving less than one-sixth the yield of the other, really had the longest tongues.

Both colonies were managed as nearly alike as could possibly be done, up to about the first of July, when the Iowa bees began to swarm, and I had to put out more than double the days of the best part of the harvest. They were not susceptible to the management of the apiarist as were the others, but with the honey harvest they went to an excess in breeding, and to the harvesters at this point it seemed a superfluous number of workers which took to swarming rather than to honey-gathering, and thus the season was frizzled away to little advantage to the apiarist.

My bees this year, as in years past, that the bee which is the most susceptible to the management of the apiarist, so that a maximum amount of bees can be brought on the stage of action, with little, if any, desire to swarm, just at the commencement of the honey harvest, with as few bees at any point to which this object, is the bee which rolls up the honey to the account of the aprist every time.

But I hear some one saying that the length of the tongues of those bees varied only very few-tenths of a hundredth of an inch, anyway. This is right, and from considerable correspondence of late I am led to believe that Italian bees from various parts of the country, and from colonies that gather little or much honey, all have tongues of practically the same length. Had those tongues of Italian bees been given the poustest yields of honey been measured on the start, instead of offering prizes for the longest tongues which gathered the most honey, more real facts would have come to light, with less of public deception.

It is always well to go a little slow until assured of the ground upon which we stand, lest some one may be deceived by statements which are made prematurely; the same being premature through our not having investigated till we have gotten at the bottom facts in the case.

Ondago Co., N. Y.

A Short Report—Selling Honey too Cheaply, Etc.

By MRS. L. HARRISON.

Our honey is all taken off, and put away nicely (Oct. 28), and I estimate that the is a supply for two families, from our apiary of 40 colonies. Our apiary, prior to this season, showed poor sections, but the losses each succeeding winter were more than the summer's increase; and this is the condition of aparies generally in this part of the State.

The newspaper who advertises largely announced lately that he had some fine honey of this year's production, which he was selling at 15 cents per pound. Honey was worth 20 cents, but he had a chance to buy 250 pounds cheap, and his customers would have the mistake of 125 honey, but no losses. When there is a short crop of corn or potatoes, the price goes up, and why should not honey? No line comb honey should be sold for less than 20 or 25 cents per pound at retail. There has been a steady decrease in the number of colonies, and a less secretion of nectar than formerly.

I think that there are more sources for honey in the city, per acre, then in the country. At almost every home a few flowers are cultivated; lawns are sprinkled frequently with a
hose attached to hydrants, and the modest white clover dots the green. Porches are shaded with Columbine or Maderia vines, which are favorites with bees; there are beds of portulaca, mignonette and other flowers. The city parks have much bloom, and sweet clover, both white and yellow, have pre-empted all unscaped lands. A failure of fall honey has never been reported in this locality.

Preparing Bees for Winter.

I get everything ready beforehand. I use new sheets of Indian-head muslin every year; tear it up so large that it will extend over the edges of the hive, so that when the cap is shut down upon it, it is utterly impossible for a bee to get up into the cap. I pick off all ravellings, iron them smooth, and pile them up on a board. I gather baskets of dry maple leaves. When all was ready, on one of our quiet October days, I uncovered the bees, put a hill's device upon the combs, spread over the sheet, and set on the cap or upper story, poured in a good bed of leaves, and a chaff cushion above them: then I cut away with a piece of section between it and the cap, thus making a little crack, so that fresh air will circulate above the packing. This was all done so quietly that the bees were not disturbed, and no smoke was necessary. The chaff cushions have been in use a good many years, so I put in leaves, as chaff is not handy to get.

The hives were all heavy with well-ripened, sealed honey, gathered from sweet clover, goldenrod, Spanish needles, boneset, polygynum, and other wild and cultivated flowers.

Mulberries.

One year the last of April, I visited the navy yard at Pensacola, Fl., and while there gathered a handful of ripe white mulberries; they were very rich, and so juicy and sweet that they made my fingers sticky. A friend, who was a missionary many years in Turkey, says that in that country they press out the juice, boil it down into a syrup, and call it 'honey.' The residue—skins and seeds—they dry, and keep to feed their donkeys during the winter.

Peoria Co., Ill.

Questions and Answers.

Conducted by Dr. C. C. Miller, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—Enron.)

Feeding Bees for Winter Stores.

I got caught in that cold spell, and one colony is short of stores; that is, it has a little over eight pounds of unsealed syrup left. 
1. Will that unsealed syrup cause trouble?
2. How can I make sugar candy? I made some last winter, but it was so hard the bees could not take it. I made it according to the book—
3. How much candy should I give that colony to carry it through the winter? That is, how many pounds of sugar should I make into candy?
4. Are four Langstroth frames full of honey enough to winter a strong colony?
5. Are forest leaves a good, warm packing?

Minnesota.

Answers—1. There is some danger of it, especially if it was late, there will be less danger of trouble in the cellar than outdoors.
2. I doubt being able to tell you any better than the books. Two kinds are given. Schol or Good candy, which is perhaps the better kind, being a stiff dough made by kneading the extracted honey into sugar; and the old kind made by evaporating sugar syrup. It is quite possible that your candy was all right. No matter what kind of candy you have, the bees in winter are not likely to take it unless it is very easily within reach. See that the candy is directly over the cluster, or else that it is in a frame hung close beside the cluster so as to touch the bees.
3. Having already 8 lbs. of syrup, 22 lbs. of candy will do for a full colony.
4. Yes, if by "full" you mean bulged out from top to bottom and sealed out to the lower corners. But as you are likely to find them in the brood-chamber, six or eight would be nearer the mark.
5. Yes, if dry, they are excellent.

Various Questions.

1. Will Italian queens reared from a thoroughbred mother mated to a black drone produce as good honey-gatherers as if mated to an Italian drone?
2. Does it take more honey to winter a colony of Italians than a colony of blacks?
3. Do queens lay during the night?
4. Do the worker-bees work in the hive at night, such as build comb, feeding larvae, etc.?
5. About how much honey does it take to winter a colony of bees in this latitude? Our bees usually start to swarming here about the first of April, if the spring is not late.

South Carolina.

Answers—1. Sometimes they will, and sometimes not. The first cross are generally good, but after that the improvement generally goes backward.
2. You will probably find no difference, if you compare 100 colonies of Italians with 100 colonies of blacks of equal strength. You will find considerable variation, however, in single colonies, whether yellow or black.
3. Yes, indeed.
4. Yes, indeed.
5. I don't know, but I think it is not safe to have a colony go into winter quarters with less than about 30 pounds unless you intend to feed them in the spring before flowers appear. If I am wrong in this I wish some South Carolinian would correct me.

The Afterthought.

The "Old Reliable" seen through New and Unrechable Glasses. By E. E. HasT, Sta. B Rural, Toledo, O.

Dr. Strickland not for "Meltose."

I hasten to make amends for a particularly atrocious meaning of my blundering pen. Dr. Strickland was not acting as a friend of meltose, ignorant of its uses, but more care in reading up the whole thing should have shown me that. He devotedly, though sincerely, located him on the wrong side of the fence and went on. Monkey at the lever of a 1½ H. P. machine is capable of mischief, is he not? Page 611.

Those twin brides.

Compliments to those twin brides and their grooms on page 721. Doubtless the boys themselves (on a slight inspection) can tell the brides apart. If the rest of the world makes a mistake occasionally, why, that doesn't signify.

Fixing Up Other People's Language.

And so Dr. Miller wants Prof. Cook and myself to settle matters between us. Might as well ask Kitty and Towser to settle their differences by a little private confab in the back yard. I just keep getting my head muddled and maddened all the time. It's just monstrous the way Prof. Phantom Cook is trying to compel 100,000,000 people to make bricks without straw. All who speak the English tongue come in contact with certain familiar objects. They have to call them something. Not one in a hundred of all these people can tell which is worm and which is larva—haven't the entomological knowledge required to do it. But here comes Phantom and says, "You must call them something." Leastwise, if he doesn't put it as badly as that, he is on the road in that direction—"I'll brand you as disgraceful perverters of the English tongue." If it was only one case, and entomology was the only science extant, we might think of yielding just for the sake of peace in the family. But science has a hundred branches (going to be); and nobody is, or possibly can be, familiar with all; but all, I fear, will have Prof. Cooks that will be emboldened to make similar demands of us, if we do not stand for our rights. Suppose a few hundred astronomers should insist that the entire English public leave off saying "shooting stars" and say "bolides." And what a supreme
as a geologist would make of himself trying to make everybody use the term "rock" precisely as he uses it! Call out the police and the ambulance. Dear Boss: I am going to throw the window open.

In some things the rich man has more rights than the poor man; and the learned man has more rights than the unlearned. That may sound shocking to some, but I will grant it freely. But—the right to have a language to express his ideas—a language which he can express his ideas, without distress, and without annoyance, and without being called a fool—that does not by any means go with the above. That's one of the inalienable rights of man, like "life, liberty, etc."

When comes, but I, for one, hardly believe that shading the lower dish will prevent the sun from spoiling the honey. Page 600.

FLOWERS INTOXICATING AND HOLDING BEES.

When only few and rare plants were accused of holding bees by some sort of intoxicant the case sounded stronger than it does now that the attempt is made to accuse the basswood of the same. But in the belief that the lower dish will prevent the sun from spoiling the honey.

The cow.

Is any home circle quite complete without the cow? I would never consent to be without this important adjunct in every home. In this day of food adulteration it is hard to know just what we are eating, but if we have our own cows, and do our own milking, we may be pretty sure on this point.

We are very fond of milk at our house, and none of us complain if a good proportion is richest cream. I take great pleasure in my glass or bowl of milk, and, I believe, as much in seeing the other members of the family as they diminish the sugar in it. We are certain that in milk there are no impurities. In it, too, we get perhaps as balanced a ration as we can obtain anywhere. It is Nature's own concoction. We never grew so fast as when in our babyhood. Then milk was our exclusive diet. I suppose in milk we get just about the right amount of sugar which has no taint of glucose in it; just the proper proportion of fat, which is certainly one of the most appetizing and wholesome of all the varieties of oleaginous material for the digestive system. We are certain that in the milk we have enough and most wholesome albuminoid.

I also like to take care of my own cow and to do my own milking. So many people are content to keep their cows covered with filth, and are so scrupulously careful not to brush or clean them as to commence to draw the milk, that I find it not at all agreeable to patronize the milkman.

My cow must be as neat and clean as my driving horse, and I would not think of commencing to milk until the cow was absolutely clean in all respects. Our private dairymen, whom I know, get the creamery price for his butter. When asked why, at one of our Farmers' Institutes, he said, "I never milk without thoroughly brushing, and, if necessary, at all thoroughly washing the cows, all about the udders." Neither would I have any one milk my cow who would wet the teats before or during the milking. Wet milking and neatness never ride in the same carriage.

We have just secured a cow coming to our neighborhood—share the milk. Four families own the cow and share equally the expense and the profit. As I have said before, I think such partnership among nearest neighbors tends to harmony, and has more to recommend it than the old-time economy gains. Also, each person in a family gets a quart of milk a day. She does a good lot of eating. I like to see her eat. Of course she must eat or she could not give us so liberally of her very substance. Where do we have a better example of real, personal sacrifice than we see in the cow? I fancy our cow has a sort of a benignant look in her very eyes. Mrs. Cook remarked only a few minutes ago, "How kindly our cow looks at us: and what a pretty face she has." I thought to myself, "Why not? If any one has a right to look kindly it is surely one who gives herself, as does our cow, to add to the pleasure and happiness of others."

Our cow has been giving milk only a few days. The spring into action of the great milk-glands has made the udder tender, so that as I draw the milk the parts are irritated, and she raises her foot, often many times, when I am milking, and not always in gentlest fashion. There are many ways to meet the all too numerous things. I could use my boot or stool, and possibly she might be cowed into quietness. No doubt in doing this, even though I did succeed in quieting her, I should do it at the sacrifice of milk. Rough treatment makes milk go with the wind, as we say. If milk does not go together.

The other course is to milk very gently, and perhaps very slowly, and thus not hurt even the sensitive milk.

I hardly need say that this is the way that I have proceeded, and I am very happy to state that it has worked like a charm. I am sure, too, that treating or getting the full and a full milk, and just assure that I am in no danger of ruining the cow.

I wonder if we all realize that we are never violent with our animals, especially with our cows, exhibiting to great extent. We hardly realize how delicately sensitive our cows are to any disturbance. A large dairyman told me a few days since that he never changed his cows from one pasture to another without losing several pails of milk; and this happened through he put the cows to a pasture where the disturbance attending the change was what reduced the milk flow. The dog, the milk-stool, and the boot too often bring the same result.

Propos to the above is the too common habit of pouring milk because she does not "give down" her milk. The philosophy of yielding or withholding the milk is this: The milk is in very numerous small tubes, which are thickly set in muscular tissue. These small muscles are the striated type, and are entirely beyond the control of the will. Thus, we are absolutely sure that the cow has no direct control of the matter. Rough treatment, which will produce a nervous shock, may effect to press the milk down the teats. It would be only a few that we have made a bad matter worse, and done a beastly, mean thing. In all such cases stoning or kicking are strictly in order; but the cow should not be the recipient.

CATS AND DOGS.

I don't mean cats and dogs in the sense of "scraps" in the home. Oh! that parents who suffer ill-will, fault-finding, family-jars to invade the sacred precincts of the home could realize their terrible mistake! They are the only real legacy to the ones entrusted to their care. Divorce has always seemed to me one of the blackest pages in our social history. Separation between the chief partners of the home circle is nearly as bad. Yet, I quite agree with Mrs. W. H. Page in the Christian Register, "The daily spectacle of a discordant home is worse for the child than the known separation of its parents." Cats and dogs, then, as used to designate fierce word battles, where word-fights have no business, is not my theme— I mean real cats and dogs.
We have two tiger cats. We all like them, and if purring is a sign of contentment—and who can doubt it?—then our cats are not pining for a new home. No one would wonder at this, if he should see the great basin of freshest, sweetest milk that I give them twice daily, as I come always attending them with a high cup, full, of course. I always watch them as I milk. So I have to be neat and particular, as I am always watched. My wife and daughter insist on this full milk ration. I am not the only one who thinks nothing of our good cats. I often hint to them that if ever I do get jealous of those cats it will surely not be without provocation.

One of these cats is a beauty. He is as boldly striped as a veritable tiger. Everybody praises "Toots." "He is such a beauty." Toddlies is more plain in garb. Few visitors discover on their first visit that any woman is clad in clothes as dotsy as Mrs. Cook and daughter take his part, and warm up as they portray his good points. These cats are treasures. Mice used to run riot in the barn, and took too generous toll of hay and meal bag. Now I never see any mice except as Toots or Toddlies come to me one that specially pleases them, and, like well brought up cats, wish to share the pleasure with me.

— Even a better use than this is the pleasure they give the dear ones of our home circle. It is good for us to lavish attention and care even on a feline member of the family. And I am sure that loving them insures more love to those of the household more deserving of love. Neither do our cats disturb any of our neighbors. Indeed, they are fondly petted by all.

I don't feel so about dogs. I wouldn't have one. They do not catch mice, and are only valuable as pets. And are they not too often a nuisance to all the neighbors? No hour of night is sacred against their vociferous yelps. And how few are too well bred to pitch wildly out at the passing carriage or equestrian? Unless we can get real gentleman dogs—and they are rare in California—let us replace every dog on the place with a good, handsome cat.

**DIVORCE THE LAWN AND TREES SHRUBS.**

What are so exquisitely graceful as date-palms—the Phoenix canariensis? They are great, living fountains of golden milk. A neighbor had one right on the lawn. It had no business there. An open lawn is too beautiful a feature of the landscape to be invaded even by handsome tree or shrub. Again, the grass seems to have learned this, and proceeds at once, upon occasion, to throttle the very life from any invader. Thus it was that the date-palm was yellow and sickly. Why, my date-palm, almost near enough to shake hands with the other, grew more in three years than did that one in more than double the time. The grass washed the water and the fertility, and took it, and the poor palm could only turn yellow—not green—with envy.

A new neighbor has purchased the place. As the palm was on the edge of the lawn, or to one side, she digged about it and put the too-greeny grass-blades to route. And, presto! the palm doesn't look like the same plant at all. The sickly yellow is replaced with brightest green, and it has grown more in one short year than in several long previous ones. It just laughs now, and were it not that its strong roots had gotten such a hold, I veritably believe it would dance.

Let us all keep trees and shrubs away from the lawns.

**THE BEE IN LAW.**

Bee are free nature, i.e., wild by nature, and possess no substantial value as having what is called animus revocandi, or a usual habit of returning whence they have escaped. During this temporary absence they remain the property of the original owner (2 Kent, Com. 348). The law, as Blackstone says, "defines this possession...for instance, the purpose or more unusual occupation; for my tame hawk that is pursuing his quarry in my presence, though he is at liberty to go where he pleases, is nevertheless, as to his own use, the hawk of my neighbour." So are my pigeons, and bees that are flying at a distance from our house and are chased out of my park or forest, and is instantly pursued by the keeper or forester; all which remain still in my possession, and I still preserve my qualified property in them. But if they stray without my knowledge, and do not return in the usual manner, it is then lawful for the stranger to take them" (2 Blackstone, Com. 352).

So, in the civil law, Gains says: "In respect of such animals as are in the habit of going and returning, as pigeons and bees and deer, when the owner is accustomed to go into the woods and fields and come again, we have this traditional rule: That if they cease to do the thing, and it is very rare that they also cease to be ours, and become the property of the first taker; now they appear to cease to have the animus revocandi when they have discontinued their habit of returning. This theory may be compared to the rights of property in animals at common law, when the law requires certain artificial measures such as taming them or offering them food and drink, but not, as in the case of invading animals, which return from the natural wild. The highest authority is that the only ownership in them is residuary. In consideration of the facts that a character is bestowed on every Freeman to be entitled to the honey found within his own woods, affords great consideration to the doctrine that a qualified property may be laid in bees in consideration of the good nature, the common possession, and the benefit of the remote neighbors also."
REVERSIBLE WALL MAP

OF THE

UNITED STATES AND WORLD,

WITH SPECIAL INSET MAPS OF

China, Cuba, Porto Rico, The Philippines, Hawaii, and Alaska,

Especially prepared to meet the demand for a first-class map that will give a quick, general idea of location of events the world over, and particularly to the United States and our territorial possessions. Very useful in every Home and Office.

66 x 46 INCHES IN SIZE.

ELEVEN BEAUTIFUL COLORS.

Best and Most Necessary Map Ever Issued.

No Home or Business House should be without it.

The Maps are works of art. The engraving is plain, bold, and decisive. The color work is elegantly contrasted, but not gaudy.

Perfection and Artistic Elegance

a salient feature of this map not approached by any similar publication.

Marginal Index

is one of the invaluable features.

It gives an alphabetical list of countries, their location on map, style of government, population, area, products, minerals, imports, exports, etc.

The 1900 Census

of the largest American Cities is given.

It has been pronounced a Photograph of the World.

One side shows a grand map of our great country, with counties, railroads, towns, rivers, etc., correctly located. The other side shows an equally good map of the world. Statistics on the population, cities, capitals, rivers, mountains, products, business, etc., a veritable photograph of the United States and World.

The map is printed on heavy map paper and is mounted on sticks ready to hang. Edges are bound with tape.

On the reverse side is the Library Map of the World. The largest and most accurate map on Mercator's Projection ever produced. The political divisions are correctly detailed and beautifully outlined in color. The ocean currents are clearly shown and named. Ocean steamship lines with distances between important ports are given. A marginal index of letters and figures enables one easily to locate every country in the world. A series of short articles in alphabetical order is printed around the border of this map in large, clear type, containing valuable information concerning agricultural, mining, and manufacturing statistics, also the value of imports and exports in dollars. The area, population, form of government, and chief executive of every country in the world is given up to date, also the names of the capitals and their population. The Inset Maps are elegantly engraved and printed in colors. They are placed in convenient positions around the United States map, and will be invaluable to every person desiring a plain understanding of our possessions. An inset map of China on the World side of map adds to its value.

Two maps forward it free as a premium for sending as Three New Subscribers at $1.00 each; or for $2.00 we will send the Map and Address.
OUR NEW CATALOG, describing and listing the FINEST LINE of BEE-KEEPERS' SUPPLIES IN THE WORLD, will be ready about first of the year. If you have not received a copy annually, send us your name and address and one will be mailed you free. Prices will be same as last season with the exception of the narrow, plain sections with no bee-wax, which will be 25 cents per thousand less.

G. B. LEWIS COMPANY, Watertown, Wis., U. S. A.
Excellent shipping facilities and very low freight rates for Southern and Eastern territories.

BEST

Extracted Honey For Sale

ALL IN 60-POUND TIN CANS

Alfalfa

Honey

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood

Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two 60-pound cans of Alfalfa, 5 cents per pound; four or more cans, 7½ cents per pound. Basswood Honey, 7½ cents per pound. Cash must accompany each order. You can order half of each kind of honey, as you desire. The cans are boxed.

Absolutely Pure Honey

The finest of their kinds produced in this country.

Read Dr. Miller's Testimony on Alfalfa Honey:

I've just sampled the honey you sent, and it's prime, thank you. I feel that it is something of a heretic, to tell several thousand pounds of honey of my own production and then buy honey of you for my own use. But however loyal one ought to be to the honey of his own region, there's no denying the fact that for use in any kind of hot drink, where one prefers the more wholesome honey to sugar, the very excellent quality of alfalfa honey I have received from you is better suited than the honey of more marked flavor, according to my taste.

C. C. Miller, Mclnery Co., Ill.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & Co., 144 & 146 Erie St., Chicago, Ill.

Please Mention the Bee Journal when writing Advertisers....

of the property of the soil whereon they are found."

Identity.

One of the chief difficulties in reclaiming bees is in the almost impossible identification thereof. Many curious cases of doubtful or disputed identity might be illustrated by the singular fortunes of resemblance between bees, not only in their general appearance, but in certain characters of the accidental or ordinary. Positive recognition of peculiar habits and working of bees is too difficult to suffice to the claim of identity. Courts have recognized photography as a proper means of identification of the thing in dispute; but there is error in the record, so far as we have been able to discover, where a claimant has been able to reclaim his bees by means of photography. Various other cases of identity are illustrated by the concurrence of their several characteristics. This proof is too remote, and the question of identity is in the jury. The court cannot presume identity of bees.

Transportation of Bees; Contract of Carriage.

The exact character of the contract for the carriage of animals has been the subject of much judicial discussion. The prevailing opinion, however, is that common carriers are liable for injuries to animals when resulting from the acts of God or the public enemy, or from the peculiar nature of the body of animals, unless they are carried in transit with railway companies whether they will accept the full responsibility of transporting bees, yet if they do so without any express restriction, they are liable as common carriers. But they may, for a less hire, agree simply to transport bees, furnish cars, etc., and if the shipper and owner of the bees agrees to the lower rate, he can not hold them as common carriers. For a given reward they profer to become his carrier; for a less reward they profer to furnish the necessary means that the owner of the bees may be the owner and carrier (Kinds v. McElroy, 91 N.Y. St., 247). In the case of Mrity v. Derenay, 54 Fed. R., 718, the United States court held that, vessel stricken and destroyed, and filled with water, and a cabin containing bees floated to the shore, but no effort was made by the master to use the bees in saving them, the steamboat line was held liable for damages to them, though the vessel was insured and was abandoned to the underwriters as a total loss.

Bees the Subject of Larceny.

Bees in the possession of the owner are the subjects of larceny, says the Indiana Supreme Court in State v. Murphy, 8 Bledsoe, 418. Further, the court holds that, when bees are in the possession of any person, they are the subject of larceny, and, on that subject, whatever constitutes possession. Generally it is

Reduced Rates for Christmas and New Year Holidays.

The Nickel Plate Road will sell tickets Dec. 24, 25, and 31, 1901, and Jan. 1, 1902, at rate of a fare and one-third for the round trip, to any point located on the Central Pennsylvania terri-tory, good returning to and including Jan. 2, 1902, Pullman service on all trains. Individual club meals ranging in price from 35 cents to $1.00, served in Nickel Plate dining-cars. Address, John Y. Calahan, General Agent, 111 Adams St., Chicago, for particulars. Depot, Van Buren St. and Pacific Avenue, on the Eastern Loop.
regarded that the owner of the soil upon which the bees may be found is the possessor thereof. While the rights to animals *free miter* and to the soil and others, have been fairly settled by a considerable series of cases, the relative rights of parties, both of whom acknowledge the superior rights of the owner of the soil, seem never to have been precisely described. But in a recent Rhode Island case (Leicester v. Bowers, 10 R. I., 39,) the plaintiff, without permission, placed a hive of bees upon the land of the defendant, and in the superior court, also a trespasser, removed the bees and honey which had collected in the hive. The court found that there was no action of action, holding that neither plaintiff nor defendant had any title or right to possession to the bees or the honey. It then searched through the law to find a basis of action, and a trespasser. The court seems to have found just what a person has the right of possession to collect the honey and bees which has collected in the hive. The court quite correctly decided in favor of the plaintiff, reasoning that the title to the soil is not dispossessed from the possession of the person who has the right to take the bees and honey which have collected on it.

**Fair Honey Crop.**

In our locality we have very changeable weather in winter—from extremely cold to warm. We seldom have over one week that bees do not fly, if left on the summer stands. In the case of the bee-keepers in my kind whether it would be an advantage to winter bees in a cellar under such conditions or not. Our honey crop was fair the latter part of the season. Bee-keepers in this locality do not read bee-papers; one reported fool brood, which on inquiry, proved to be broad in the supers. C. W. SUTHER. Garfield Co, Utah, Nov. 20.

**Bees Worked on Strawberries.**

I was very busy the past summer. In fact, I believe I never worked harder in my life, but it has been a good year for me. I had $500 worth of strawberries, and they were fine, big, and fine flavors—green leaves and a good fruit. I have 200 cherry bushes in June. My bees did quite well, but I did not have time to attend to them at the proper time. My best colony filled 10 frames and 50 sections of hives, but in two super frames and after reducing them for honey. I plan to do 50 pounds to the hive, but my scales weigh only 60 pounds, and I put a brick on for a weight of 50. I think this weight would not weigh them. I think they are all right for winter. My lightest colony weighs 47 pounds, being the only colony which is not reduced to a mere skeleton. I do not think I will have to feed for this winter. Basswood bloomed very

An American Association
I am a bee-keeper, fruit-grower and farmer.
I have about 20 colonies of bees, and so far
have succeeded, with the help of the "Old
Bee-Keeping," to sell a large crop of nice comb
honey every year, besides having it on the table at meal time, as my family and I
find we can get along without it. We have
honey the last few years to the same store-
keeper for 12½ cents per pound, and next
year's crop is ordered before this year's
is sold.

Now for a question: Would the National
Association do all it could for its members
to get justice in such a case, though honey-dealers are its specialty—
EDITOR.

Hoping for a Good Wetting.
Although I am well advanced in years, and,
unfortunately, an invalid, I manage to attend
my bee-keeping. The best way for one who
has a little extra labor-cost during the past
winter, feeding, and fighting bee-diseases, etc., I am still
"in it," and expect to stay with it, whether
the American Bee Journal as a welcome visitor
and guide.

The first rain of the approaching winter
season fell here Oct. 27, and again Nov. 9
and 11, and we are all hoping for a good
wetting. The coming winter looks set for
nothing but a healthy winter. After suffering
my bees on the summerstands, but, as
a precaution on account of the high altitude
and cold snaps, we are packed a little
warmer.

GUST VON.
Riverside Co., Calif., Nov. 16.

A Report—Red Clover.
My bees did fairly well the past season,
averaging from 25 to 35 two-pound
sections of honey each. The weather was
fair, and I started the season with 24 colonies, increasing
to 36, and two swarms left for the woods.
I have nearly all my honey in the home
market. My bees worked on red clover as
much as on the white. Clover is in good
condition this fall—a few large, and things are booming. I would like some
of the "wise heads" to tell me if red clover
would suit Southern and Northern
peoples. I believe many do not, here in Iowa; or is it locality?
Page Co., Iowa, Nov. 12.

JERRY SCOTT.

Poor Prospect for White Clover.
I do not know what we will do for honey
next year. As the white Clover is killed by the
drought. No. 1 honey here is worth 15
cents per pound by the case. I sold all I had
at the price, and I had no swarms to speak of
this year. I live the swamp on the old
stand, and the swarms have all been made
in winter quarters in good condition this fall. Although
I can not agree with it in everything, I do not see
how I can get along without a good
honey-extractor. I have read of many who can
Bee Journal.
J. M. MOTE.

Favors the Honey-Extractor.
The honey-extractor is an article little
used by farmer-beekeepers and many others
who keep but a few colonies. Yet a good
extractor is one of the very necessary things
every bee-keeper should have, even if one has

The National Association.
I am a bee-keeper, fruit-grower and farmer.
I have about 20 colonies of bees, and so far
have succeeded, with the help of the "Old
Bee-Keeping," to sell a large crop of nice comb
honey every year, besides having it on the table at meal time, as my family and I
find we can get along without it. We have
honey the last few years to the same store-
keeper for 12½ cents per pound, and next
year's crop is ordered before this year's
is sold.

Now for a question: Would the National
Association do all it could for its members
to get justice in such a case, though honey-dealers are its specialty—
EDITOR.

Hoping for a Good Wetting.
Although I am well advanced in years, and,
unfortunately, an invalid, I manage to attend
my bee-keeping. The best way for one who
has a little extra labor-cost during the past
winter, feeding, and fighting bee-diseases, etc., I am still
"in it," and expect to stay with it, whether
the American Bee Journal as a welcome visitor
and guide.

The first rain of the approaching winter
season fell here Oct. 27, and again Nov. 9
and 11, and we are all hoping for a good
wetting. The coming winter looks set for
nothing but a healthy winter. After suffering
my bees on the summerstands, but, as
a precaution on account of the high altitude
and cold snaps, we are packed a little
warmer.

GUST VON.
Riverside Co., Calif., Nov. 16.

A Report—Red Clover.
My bees did fairly well the past season,
averaging from 25 to 35 two-pound
sections of honey each. The weather was
fair, and I started the season with 24 colonies, increasing
to 36, and two swarms left for the woods.
I have nearly all my honey in the home
market. My bees worked on red clover as
much as on the white. Clover is in good
condition this fall—a few large, and things are booming. I would like some
of the "wise heads" to tell me if red clover
would suit Southern and Northern
peoples. I believe many do not, here in Iowa; or is it locality?
Page Co., Iowa, Nov. 12.

JERRY SCOTT.

Poor Prospect for White Clover.
I do not know what we will do for honey
next year. As the white Clover is killed by the
drought. No. 1 honey here is worth 15
cents per pound by the case. I sold all I had
at the price, and I had no swarms to speak of
this year. I live the swamp on the old
stand, and the swarms have all been made
in winter quarters in good condition this fall. Although
I can not agree with it in everything, I do not see
how I can get along without a good
honey-extractor. I have read of many who can
Bee Journal.
J. M. MOTE.

Favors the Honey-Extractor.
The honey-extractor is an article little
used by farmer-beekeepers and many others
who keep but a few colonies. Yet a good
extractor is one of the very necessary things
every bee-keeper should have, even if one has

THE
The Bee-Keeper's Guide;
Or, Manual of the Apiary,
BY
PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thou-
sand—$1.25 postpaid.

A description of the book here is quite unne-
cessary—it is simply the most complete scientific
and practical work published today. Fully
illustrated, and all written in that most fasci-
ating style. The author is also too well-known to
the whole bee-world to require any introduction.
No beekeeper is fully equipped, or his library
complete, without THE BEE-KEEPERS GUIDE.

This 16th and latest edition of Prof. Cook's
magnificent book of 460 pages, in neat and
substantial cloth binding, we propose to give
away to our present subscribers, for the work of get-
ing NEW subscribers for the American Bee
Journal.

Given for TWO New Subscribers.
The following offer is made to present
subscribers only, and premium is also given to
the two new subscribers—simply the Bee
Journal for one year:
Send us TWO NEW SUBSCRIBERS to the Bee Journal with $2.00, and we will mail you a copy
of Prof. Cook's book FREE as a premium. 
Prof. Cook's book alone sent for $1.25, or we club it
with the Bee Journal for a year—both for only
$1.75. But surely anybody can get only TWO
NEW SUBSCRIBERS to the Bee Journal for a year,
and thus get the book as a premium. Let every
body try for it. Will you have one?

BEE-SUPPLIES!

"Root's Goods at Root's Prices"

Everything used by beekeepers.

A New Bee-Keeper's Song—

"Buckwheat Cakes and Honey"

Words by EUGENE SECOR.

Music by GEORGE W. YORK.

This song was written specially for the Buffalo convention, and was sung there. It is written for organ or piano, as have been all the songs written for bee-keepers. Every home should have a copy of it, as well as a copy of "THE HUM OF THE BEES in the APPLE-TREE BLOOM"

Written by EUGENE SECOR and Dr. C. C. MILLER.

Prices—Either song will be mailed for 10 cents (stamps or silver), for both for only 15 cents. Or, for $1.00 strictly in advance payment of a year's subscription to the American Bee Journal, we will mail both of these songs free, if asked for.

Texas Bee-Keeprs.

New Branch Office. 438 W. Houston St., San Antonio, Texas. Rates of transportation from Medina in less than car-load lots are high, and it takes a long time for a local shipment to reach Southern Texas points.

Low Freight and Quick Delivery, San Antonio as a Shipping-point.

Our Managers. We have secured as managers Mr. Udo Toepperwein, formerly of Leon Springs, and Mr. A. Y. Walton, Jr., both of whom are well known to the bee-keepers of South and Central Texas. They are also thoroughly familiar with practical bee-keeping and all matters associated with it, and any orders sent to this branch will receive prompt, careful attention.

Our Goods. As usual our motto is to furnish the best goods of the most approved pattern. We do not undertake to compete in price with all manufacturers. Bee-keepers have learned that it does not pay to buy cheap supplies, for a saving of 10 cents on the first cost of a hive may be a loss of many times this amount by getting poorly made and ill-fitting material. Every year brings us many proofs that our policy of "the best goods" is a correct one.

Our Catalog. Very few changes in prices will be made in our new catalog, so do not delay in sending your order, but send it at once. You will be allowed a refund if lower prices are made, and in case of higher prices ruling in the new catalog, if any, you will secure the benefit by ordering now. Catalog and estimates may be had by applying to the address given below.

Our Invitation. Whenever you visit San Antonio you are invited to call at our office and make it your headquarters. Here you will find a display of Apiarian Supplies not equaled elsewhere in Texas. You will also find on file the leading Bee-Journals to pass pleasantly your leisure hours.

Spanish Catalog. Some of you may read Spanish, or have a bee-keeping friend who does. If so, call for our Spanish catalog. It's sent free.

To promote and protect the interests of its members.
To prevent the adulteration of honey.
To prosecute dishonest honey-dealers.

BOARD OF DIRECTORS:
H. Willard, Dr. C. C. Miller.

EXECUTIVE COMMITTEE:
Ernest R. Root, President.
R. C. Akin, Vice-President.
Dr. A. B. Mason, Secretary, Toledo, Ohio.

Eugene Secor, General Manager and Treasurer, Forest City, Iowa.

Membership Dues $1.00 per year.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

Note.— One reader writes: "I have every reason to believe that this would be a very good idea for every bee-keeper to wear on his coat lapel, as it will cause people to ask questions about the bee-box, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a better opportunity to enlighten many a person in regard to honey and honey bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

The Novelty Pocket-Knife. Your Name and Address on one side—Three Bees on the other side.

How to Get this Valuable Knife.— We send it postpaid for $1.26, or give it as a Premium to the one sending us the first New Subscriber to the Bee Journal for $5.00. We will club the Novelty Knife and the Bee Journal for one year, both for $1.00.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, III.

Extracted Honey For Sale

ALL IN 60-pound Tin Cans.

Alfalfa Honey

This is the famous White Extracted Honey gathered in the alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Basswood Honey

This is the well-known light-colored honey gathered from the tizo, esculent-labeled basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:

A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two or more 60-pound cans of Alfalfa, 75¢ per pound; Basswood Honey, 35¢ more per pound than Alfalfa price. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are two in a box, and freight is not prepaid.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, III.

The Novelty Pocket-Knife

How to Get this Valuable Knife. — We send it postpaid for $1.26, or give it as a Premium to the one sending us the first New Subscriber to the Bee Journal for $5.00. We will club the Novelty Knife and the Bee Journal for one year, both for $1.00.

30¢ Please allow about two weeks for your knife order to be filled.

HOWARD M. MELBEE, HONEYVILLE, O.
The Chicago Convention held its best meeting last week. It was also the most largely attended, the room being crowded at every session—about 100 present. There were bee-keepers from three or four different states. The discussions were taken in short-hand, so we will be able to place before our readers a complete report later on. It will easily be worth a year's subscription to the American Bee Journal. There was only one paper read, all else being interesting questions, which were discussed in a manner equal to the Buffalo convention, which report is now appearing in these columns.

Can We Have Better Gatherers?—Mr. Getaz, in this journal, has expressed the opinion that, although we might increase the size of our bee-keepers' meetings yet there was little prospect of increasing honey-gathering qualities, F. B. Simpson says in the Bee-Keepers' Review:

"The bee is not a domestic animal, or even domesticated; and we have done little to change her condition of life except to give her a better home; but by most careful selection I think we will be able to continue to increase gradually the average honey-yield until we obtain great uniformity, and, possibly, an average very near our present maximum yield."

Bee-keepers will probably wish that Mr. Simpson may prove the better prophet.

The Directors' Meetings at the Buffalo convention were held during the sessions of the convention, and a straw in gleanings in bee-culture reads thus upon the subject:

"I want to say in language somewhat emphatic, that some better way should be provided than to have Directors' meetings that keep directors out of the sessions of the annual convention of the National. It isn't fair to the directors; and if they are good for anything, it isn't fair to the convention."

Editor Root then follows with this comment:

"You are right; but the time of our national conventions is so much taken up by general convention work that it is often difficult to squeeze in a little side-committee work between the sessions. I think the time will have to come when the directors will have to consult by letter, and that the discussion of these questions will have to be done through correspondence. Such a plan is unsatisfactory, in that it gives the chairman of the Board almost exclusive power to direct. If he chooses, the work of the entire Board may be conducted from an experience based on the time I was chairman of the Board; and at that time I saw how easy it was to get things done in a hurry and plan I had."

If he suggests, for instance, that such and such a thing is to be done, and gives his reasons therefor, in the absence of any counter-argument, his proposed policy is sure to carry, when it may not always be wise.

There is good ground for the objection raised, especially when at Buffalo, the president happens to be one of the directors. If the interests of the Association seem to demand a meeting of the directors in person, it might not be a bad plan for them to convene a day or so in advance of the convention, so that all their business might be concluded before the opening session of the convention. This would be asking, perhaps, rather more than is reasonable from men whose time may be of considerable value, and who in any case give their services gratuitously as directors, and it would not be a very great wonder if in some cases, since directors are only human, a director or general manager might be led to say:

"I don't want to appear mean, but attending the convention is rather expensive business at best, and since this extra burden is put on, I can hardly afford to attend this year."

Certainly it would be nothing more than fair that an allowance should be made from the treasury to reimburse at least the expenses of the extra time.

A New White Clover is praised in the foreign bee-journals. It originated in Germany, is called rotoblat botan, and is said to yield a much larger amount of fodder than the common white clover. Nothing is said of its value as a honey-plant.

The Poison of the Sting is still spoken of as being formic acid, and it is even said sometimes that formic acid from the sting is dropped into the honey in the cell; but Dr. Langer's investigations have shown that the poison is a different matter altogether, having a mere trace of formic acid in it.

Carolinum for Hive-Paint.—This new acquaintance comes from Germany, where it is highly spoken of. An editorial in Gleanings in Bee-Culture gives considerable information regarding it. Instead of forming a coating on the surface like other paints, carolinum strikes clear through the wood, so that when one side of a 1/2-inch board is painted with it a splinter from the opposite side will taste of the material 24 hours later. It costs only half as much as good lead paint, and it is said that railroad ties saturated with it last three times as long as when not so treated.

Mr. O. O. Poppleton thinks it objectionable for hives because of the strong color of creosote, and because of its almost black color, yet he has used it for some years to preserve his hive-bottoms. The dark color would make little difference where hives are kept in the shade, although objectionable where they stand in the hot sun. Even if it be not desirable to use it for anything but hive-bottoms, it may be quite an acquisition for that purpose, for it is the bottom of a hive that rots first, and in some places the bottom is rained by ants, which would be kept at bay by the carolinum.

Those "National" Conventions.—A straw in gleanings in Bee-Culture reads as follows:

"It might not be a bad idea for each annual convention to nominate three candidates for general manager. In the last three years we succeeded in selecting the three directors whose terms expire with the following December. That's a suggestion of Editor York's. The National. It's worth considering for the future."

The following paragraph contains Editor Root's opinion on this subject:

"I do not believe it would be wise to bring about conditions or a precedent whereby the office of general manager, at least, should be changed as often as once in two or three years. When we get a good man, as in the case of our present general manager, we ought to hang on to him. One who has been in the harness, and knows how to pull, should not be made to give place to one who may be merely popular in the eyes of bee-keepers or members of the Association, and yet possibly be entirely unqualified for the meeting and important duties of the office. But I do believe Bro. York's suggestion is all right for the Board of Directors. None of us who have been so long on that Board could just as well get out, and thus place the responsibility for the success of the organization on other men whose help we need."

In the suggestion made in this journal there was no contemplation of bringing about any condition or precedent looking toward any change in the office of general manager. As the matter now stands, the manager is elected or re-elected every year. His being nominated in advance at the annual meeting would not be likely to make any change. So long as the man already in office was regarded as the best man for the place, he would be sure of nomination at the annual meeting as he would be sure of election if there had been no previous nomination. In general, there would be no need of any nomination. But there is need of nominations for directors, and as the election of manager occurs at the same time as the election of directors, the nominations should be made at the same time. There will, however, come times when it may be necessary to elect a new manager, either because the old one dies or will not longer serve, or because it is thought some other
The Buffalo Convention

(Continued from page 775.)

LENGTH OF TONGUES OF BEES.

Mr. Rankin—I had hardly expected to talk to you this afternoon, and what I have to say will be entirely extemporeous. It has been my pleasure to be connected with the Michigan Experimental Station for about five years and during that time I have not been without personal contact or something in the investigation of the length of the bees' tongues. The idea came to me at one time when I had a single colony that gathered a half more honey than any other in the yard. I began making investigations with crude machines to measure the tongues. I have been working right along on that line. I have run into a difficulty in the mating of queens—getting the queens mated to the desirable drones is the difficulty. Personally, I don't know how that is unravelled, but if I am confident it will be done some time or other. I have observed right along that a colony which gathered an exceptional amount of honey was one that had correspondingly long tongues, and the tongue for one bee in the colony is the rating for the tongues of every bee in that colony; that is, the tongues are uniform. You don't get one bee in a colony with a tongue 7 millimeters or 22-100 of an inch long, and the rest of them run away down low. Now, you see a long tongue hasn't as long a tongue as a full-grown bee, but if you gather the bees which you are measuring as nearly the same age as possible, you will have a uniform length of tongue, and I think this is one of the problems which bee-keeping will solve in the future, that is, breeding bees with a longer tongue. It isn't that we need a strain of bees just as superior to that we have now as the strain of live stock we have now is superior to that our ancestors began with. Do not let us carry this thing too far and make a hobby of it and run it into the ground, but let us keep our eyes open, and if we have one colony of bees in Michigan that is giving us exceptional returns, let us rear some queens from that colony and put those queens in from the stock that is doing the best. I have found out by talking with bee-keepers all over Michigan, that bee-keepers rear their queens from wherever it happens when the colony swarms, and no matter if that queen is producing good colony, that queen is allowed to go right on and lay eggs and be the mother of that colony. If you have an exceptional strain, produce that strain in your other colonies and bring them all up to that standard, and that is the practical side of bee-keeping to-day. In relation to in-breeding, I don't think we need the very much in-breeding of a single scheme which has been brought up that a queen will be mated to drones from the same stock. If in-breeding were carried on to an extent that would degenerate live stock, it would probably degenerate the bee. I don't think that from any of our systems—anything that we can get is not systematic enough to bring this cross-breeding to such a point that there is not possible for us to inbreed enough to hurt. I do think the bee-keeper of to-day can improve his stock by selecting his queens and his drones. If you have four or five successful colonies, by all means breed from them.

FOUL BROOD IN MICHIGAN.

Mr. Rankin—As far as foul brood in Michigan is concerned, we had some of it up there. I think my record for any one day this summer was to condemn 118 colonies, and that in two yards. Those people are all going to treat theirs. I have so far visited perhaps over 4,000 colonies. I have been on the road since July 1, and came directly from the field to-night.

Dr. Mason—Are you in accord with Mr. McEvoy when he says that a hive that has foul brood in it, does not need destroying?

Mr. Rankin—The stand I take is that if the hive is perfectly free from any drops of honey, it is probable that the disease will be produced by putting a clean swarm of bees there. If you look on the other hand, if there is any honey around the hive the disease will in all probability be reproduced. But that is not the point. We have a lot of ignorant people in our State, and when you talk to a farmer about a bacterial disease and tell him what the characteristics of a germ are; when you tell him that you can put 25,000 of them on the head of a pin, you will just stand and look at you. If you take the ordinary farmer and tell him you have no use of him disinfecting his hive, it has been my experience that he will go right out and do something which there is no use in, and which renders the treatment a failure. The principal reason why I place the stress on disinfecting hives, and in washing your hands in an antiseptic after examining a diseased colony, is, to impress upon those bee-keepers more forcibly the virulence of the germs, and the precautions they must take. I think the chlorite of lime doesn't smell so bad as carbolic acid.

Dr. Mason—What do you think of salicylic acid and borax?

Mr. Rankin—I don't like it. The salicylic acid is all right if you have it in a strong enough solution, I think it will be enough to convince a man that one
thing is right and have him stick to that.
Mr. Sleeper—How long is a bee’s tongue, ordinarily?
Mr. Rankin—They range all the way from 14-100 to 21-100 of an inch.
Mr. Sleeper—How long would a tongue have to be to be a long-tongued bee?
Mr. Rankin—Anything over 18-100 is above the average. 18-100 is about what you will find in the best-bred bees of the country and throughout the States.
Mr. Sleeper—Can bees with tongues 18-100 of an inch long gather honey from red clover?
Mr. Rankin—They can when the corolla-tubes with honey up to that point. They can find them about 35-100 to 50-100 of an inch long.
Mr. Abbott—The actual fact is that this year the corolla-tube of red clover is not more than half as long as it usually is, owing to the dry weather and the bees are all working on it now.
Mr. Betsinger—How near must the bee come to the honey-tube in order to draw all the honey out of the tube?
Mr. Rankin—I don’t think a bee can draw honey any farther than it can reach.
Mr. Betsinger—Then if the corolla-tube is so full of honey that the bee can only go half way down into the honey, it can only draw as far as its tongue is inserted, and it will stop drawing from that point. I think you will find from observation that if the bee can go half way down into the honey at all, it draws out every mite of honey that is in the corolla-tube.
Mr. Rankin—I have done that same thing. I have placed a tube of water out of a flower and held it up in your fingers and let a bee draw honey from it, it will empty the tube, but it will not do that when it is in a head and pressed tight in that? Has the bee power enough to collapse that honey-tube, which it must do? The capillary attraction holds the nectar right in that tube.
Mr. Betsinger—Isn’t it a fact that the bee takes a tube alone and handles it separate from the rest?
Mr. Rankin—That is true. But the nectar tube in the head and fastened right in there. After they drop down when they are ripe, the bee has no more to do with them. They will draw the nectar out clear from the bottom, but I don’t think they will do it when the corolla-tube is in the head.
Mr. Rankin—We have examined a good many clover-heads when the bees had gone all over them. I have then drawn out the corolla-tubes and found considerable honey at the bottom of them. I could see that from the bees that needed longer heads.
Mr. Sleeper—In relation to foul-brood germs, I understood Mr. Rankin to say that they would not hatch with the naked eye. You have looked through a microscope at these germs many times?
Mr. Rankin—Yes, sir.
Mr. Sleeper—Have you found them anywhere else except in honey?
Mr. Rankin—Yes, sir; I have found them in the tissues of the larvae that were diseased, and, of course, you know that when you take any material whatever, no matter what it is, and put it under a high enough power microscope so that you will detect the germs, you will get anywhere from ten to 500,000 species of germs.
Mr. Sleeper—They exist independent of honey?
Mr. Rankin—They exist in the bodies of the larvae which are diseased. Mr. Sleeper—Don’t they exist anywhere else except in the larvae and the honey?
Mr. Rankin—I don’t think there is anything in the hive aside from the honey and the tissues of the larvae from which the germ will get sustained, existence, will not grow in acids or anything else.
Mr. Benton—Why confine it to the larvae alone? Why not say in the paper and add that the honey may be diseased also?
Mr. Rankin—Do you know that is so? I know that this is so in the larvae. I don’t think that you will find any of these foul brood in the adult bee outside of the honey-sac. I have looked for it and failed to find it.
W. L. Coggshall—How many different forms of germs do you find—is there more than one species of foul brood?
Mr. Rankin—No; foul brood is caused by one germ—bacillus alvei—which is a specific germ, twice as wide as it is long. I have found the germ of black brood under a microscope.

RESOLUTIONS ADOPTED.

Mr. Abbott then introduced the following resolutions:

"Resolved, That the thanks of this Association be extended to the Mayor; to the Buffalo Society of Natural Science; to the Board of Education; and the committee rooms; and to Dr. Smith, President of this society, for his cordial address of welcome; and to the janitor and the janitor’s wife for their watchful care of the building; and to the local bee-keepers of Buffalo for the beautiful badges they have furnished us, and for the use of a piano."

"Resolved, That we extend to the Texas Bee-Keepers’ Association our thanks for the interest they have shown in the prosperity of the National Association by sending two delegates to attend this meeting."

The resolutions were adopted.

BOILING FOUL-BROOD HONEY.

"I have read of boiling honey from foul-brood hives and feeding back. How much water should be added, and how long should it be boiled?"

Mr. McEvoy—I don’t like to answer that question, from the fact that I never advised the feeding—the public is too careless. They will give the disease through it. They merely heat it, and they might just as well give it raw. Water, I have added nearly a third water, and sometimes nearly half, and brought it to a sharp, bubbling boil. I never noticed any bad effects from it.

Mr. Rankin—If you could be certain that the honey were boiled it might be all right. Prof. Harrison, of Cedartown, Ga., wrote last year published a bulletin on foul brood. He has demonstrated to us that you can boil the spores of foul brood for something like two hours and still produce clean feeders, but I have not seen any growth there. Do we have any spores in the honey? I have never seen any foul-broody honey fed back that did not produce the disease, but I have not had the experience that Mr. McEvoy has had. I have been in this business only a short time, and I haven’t tested it thoroughly, but I do not think it is safe to recommend the feeding back of foul-broody honey in any instance whatever.

Mr. McEvoy—I told a farmer, who would insist on feeding back foul-broody honey instead of buying it, I would tell him how to do it. I went back to examine that apiary and every one of the colonies had foul brood. I said, "Did you boil the honey?" He replied, "Yes, it was boiled." "Who boiled it?" "The girls." I said to the girl, "Did you boil it?" She said, "Yes, it was hot that I could hardly put finger in it."

Mr. Sleeper—This gentleman speaks of spores. Now I understand that they are seeds, are they not? I would like to know whether these are animal, or vegetable.

Mr. Rankin—They are the same as other germs. Some authorities say they are vegetable and some animal.

Mr. Benton—I think that they are vegetable and not animal.

Dr. Mason—Is there anything in the foul-brood line in honey that will not be killed by being boiled?

Mr. Rankin—Yes, sir; and the statement of Prof. Harrison that the spores may be boiled, I think 2½ hours, before they are killed.

Mr. McEvoy—I was going to say if they would add about half water and bring it to a sharp, bubbling boil it would kill them.

Dr. Mason—Science is a fine thing, but good, practical experience is a good thing. I had at one time about 80 colonies with foul brood, and the honey which extracted was so thick that when you could start a stick of sugar, you wouldn’t go in a chunk; and I boiled that honey and fed it back to the bees and didn’t spread any foul brood. I don’t think there is anything living thing in honey that boiling won’t kill.

Mr. Sleeper—How long do you boil it?

Dr. Mason—I make sure it is all boiled. I boiled it in a wash-boiler and I dipped it up boiling, and I poured it on the sides so as to rinse down the unboiled honey, and made sure that it was all boiled; but you want to know it is all boiled, every part of it.

Mr. Benton—All of these bacilli have their certain temperatures to which they have to be heated to be killed. Now the whole thing is this, that the absolute temperature for killing these is not known. All it needs is to determine the lowest temperature and use a thermometer and be sure that the whole mass reaches that temperature. We have boiled at 210 degrees, and this mass being much thicker was probably raised to 230 degrees before it boiled, and that is about the temperature that was reached. I am not at all certain that the bacilli did not exist in great numbers in the honey, except as an accidental impurity, and that they would not thrive as live.

R. B. Rian—My experience agrees with that of Dr. Mason. I have taken foul-broody honey and reduced it very little with water and boiled it until it was almost boil; then I poured it back to my bees without any bad results.

Mr. McEvoy—You take an old, dry comb that has had foul brood in it, that has stood for ten years, and it will give foul brood.

 BREEDING FOR DESIRABLE TRAITS.

"In breeding for desirable traits,
which is the more important, the drone or the queen?"

Mr. Hutchinson—I think one would be as important as the other.

Mr. Callbrea—My idea is that there is a difference in the vitality of drones and queens, the same as there is in human beings, the one that has the great vitality will affect the progeny the most.

Mr. Benton—I should consider the queen more important.

Mr. Callbrea—Is this the way to prepare barrels for extracted honey?

Dr. Mason—Drive the hoops tight.

**BEE-CULTURE IN TEXAS.**

Mr. Davidson—Our Secretary was to furnish us with a report of the number of colonies and bee-keepers in Texas, but he hadn’t furnished it before I left home.

Our State convention instructed our secretary to furnish us with a report of that convention, but I didn’t get it in time.

Mr. Davidson—Make it out and send it to me. (I have not received it yet—Secretary.)

Mr. Davidson—I think there are something over 2000 colonies of bees in Texas. I don’t remember the number of the bee-keepers that own them. We have a good country for bees. We have no disease among our bees. I think the greatest handicap that has been a bad impression made in the North in regard to Texas honey. The northern portion of the State produces honey gathered from wild flowers and woods, and sometimes the honey is sour and is not of good flavor. Our honey is very white. I saw a good deal of honey in the exhibit here similar to it. I would like to thank the bee-keepers of the Northern States for their kindness to the Texas representatives, and also to the Canadian bee-keepers. We wish to extend an invitation to the National Bee-Keepers’ convention, to have their meeting in San Antonio, Tex., next year, or any year after that.

Mr. Root—in regard to Texas, you say you have no foul brood or bee-diseases there. Do you have any enemies to your bees that cause destruction? You haven’t the winter that we have in the North, have you anything that you have to fight?

Mr. Davidson—No, sir. We have no enemies to the bees there that I have ever found. I have been keeping bees there for 15 years, and I have never seen any foul brood there. No winter loss at all. Our bees work nearly the whole winter. The moth does not bother bees in the South where the man understands his business and keeps his bees in the right condition.

Mr. Longnecker—Do you ever feed in the spring to stimulate brood-rearing?

Mr. Davidson—Yes, sir; we have fed them early, light honey-flow that commences about the middle of February. I never fed a pond of anything to our bees yet in the spring. The source of our main honey-flow is the mesquite and a shrub. We have the surest country for honey, I think, anywhere. We raise the rain in this country and get some honey, and if it is dry we get a great deal more. The dryer it gets the more honey we get.

Mr. Davidson—Do you have any loss from heat melting the combs?

Mr. Davidson—No, sir; I have never suffered any loss from that cause. I keep my bees under shade. I hear some complain, but generally it is where they leave the hives exposed to the sun. I have seen plenty of it where it was not properly attended to.

Mr. Toeppeerwein—I can hardly expect to hear much from bee-keepers away down in Texas, like Mr. Davidson and myself.

We have come here especially to see what you people here do, and see what kinds of honey you produce and what you do with it. We intended to bring some good-sized samples of the sections we are in there, and we produce some very nice extracted honey, which we want to dispose of. There is a very poor market for honey here, and I can get any information as to how to dispose of our honey I would like to learn of it here. I have brought a few samples of honey just to show what we have and you are a great thing in Texas. Whenever we have a drought we get our honey just the same; and in spring, if it rains, there is the cat-claw that produces honey. There is a white bush which blossoms after every rain. If it is dry there will be the mesquite, which is safe every year, so it doesn’t make any difference in our portion of Texas, we do not want to sell our honey, and if any people from the North would like to have any information about bee-keeping in Texas I would be glad to give it to them. I have seen the honey candy within two or three days after being extracted. We have a method now of putting the honey hot and forming it in glass jars with a tin cap, and I think that will keep it from granulating.

Mr. McCroy—What is your average yield per colony?

Mr. Toeppeerwein—A bee-keeper who understands his business can get all the way from 60 to 200 pounds per colony. That is, if we have a right dry season. I don’t think it is necessary to have any less than 60 pounds.

Pres. Root—Do you have any seasons of complete failure?

Mr. Davidson—No, sir; it has not proven to be, but it could be if it would rain just at the time of the mesquite blossom.

Pres. Root—Do you allow your bees to swarm where you run for extracted honey?

Mr. Toeppeerwein—Yes, sir; I let my bees swarm, and get a crop from the old colony and from the swarm, too.

Mr. Longnecker—I think you will find one of the points against buying Texas honey in the North, it is canned too much. Northern consumers won’t buy canned honey.

Mr. Toeppeerwein—What are we trying to do up here is to make connection with some concern, and have stations where people can buy the home honey beehives, get the bees and ship it in cars, and the agent comes around and buys the honey at a reasonable price and ships it up here in car-loads.

Mr. Root—I would like to ask Mr. Toeppeerwein whether they produce very much comb honey there, and what the average is per colony.

Mr. Toeppeerwein—The bee-keepers down there are getting to produce this chunk honey now. It is cut out of the frames and packed in cans with eight-inch sections, but there are getting there are there to get that done because they say there is no market for extracted honey. I wouldn’t produce any but extracted myself. Another thing, if they produce comb honey, they ought to produce it in sections.

Dr. Mason—if you can dispose of chunk honey, why don’t you produce it?

Mr. Toeppeerwein—Now, chunk honey, you have to put in foundation. There is great expense. The bees will have to build that every time.

(Continued next week.)

**Other Conventions.**

**The Colorado State Bee-Keepers’ Convention.**

BY D. W. WORKING, Sec.

It was a big thing—this 22d annual meeting of ours—and all the wide-awake bee-keepers in the country ought to hear about it. Will the American Bee Journal let me tell them?

The introduction must be brief; so that the really important matters can be given appropriate mention.

We met, as was advertised, in Representative Hall in Denver’s beautiful Capitol building, and had every convenience that the most particular bee-keeper could desire. The program was carried out with very few changes.

Dr. Root was not able to be with us, but Editor Hutchinson occupied the first evening with an instructive and entertaining talk illustrated with magic-lantern views. It was of much value, and will be furnished to the readers of the American Bee Journal, the discussions in condensed form.

The address of Pres. Aikin attracted marked attention, and the paper on long-tongued bees by Professor Gillette of our State Agricultural College, was an exceptionally instructive study of this remarkable subject. It will claim a good many “explanations”.

The exhibit of bees and bee-products was an experiment, but so successful that it will be repeated under the management of the Colorado convention.

An interesting outcome was the award of the first premium for the “best ten sections of white honey” to an exhibit of last year’s product; and this in spite of the fact that the winner had new honey entered for the same premium, and the additional fact that there were several other contestants for the prize.

The premium was Editor Hutchinson—did not suspect that the premium honey was old. Moreover, they did not seem the least bit annoyed when told what had happened.

The election resulted in the choice of a new President, J. U. Harris, of Grand Junction; and a new Vice-President, M. A. Gill. The Secretary and Treasurer were re-elected. Mr. Harris was advanced from the vice-presidency, and Mr. Gill came up from the ranks.

The Association at the present time has the largest membership in its history, and there are good reasons for believing that it will not decrease in numbers and usefulness during the coming year.

Mr. Aikin, the retiring president, after eight or nine years of faithful service, received the unanimous thanks of the Association for his successful labors. As
a private (though not a common) member, he will continue to have a large influence among the bee-keepers of the State. It should be mentioned that, during the last year, the Governor was hustled away from an important meeting of the State Bee Board, and brought upstairs to see the largest assembly of bee-keepers he had ever faced. He made a pleasant off-hand speech, promising to be of use whenever it should be possible. He will have a chance next year.

The Association did not forget to be thankful (and to express its thanks) to all who had helped to make the three-day meeting successful in every way interesting and profitable.

This brief report makes no pretense of being complete. Later on—if the editor should get items of information about the meeting may be sandwiched in between formal papers and discussions. It is not to be forgotten that the meeting was a big thing.

Report of the Utah Bee-Keepers' Convention.

The last convention of the Utah Bee-Keepers' Association was held in Salt Lake City, Oct. 5. The meeting was called to order by Pres. Lovesy. There was a good attendance, and an interesting session was held.

Col. J. C. Smith, President, Geo. How, of Utah County, by request spoke on the different sizes and kinds of bees. He said that he used the Langstroth and American hives, and that the bees must be kept dry, as it was the dampness that killed them in the winter.

Wm. Blake said that he was interested in both bees and fruit, and he thought those two industries should go together; that the job of removing the thistle should be done when the thistle was not in full bloom.

J. A. Smith, of Wasatch County, spoke of the need for more bee-keepers, and said that there was a need for more bee-keepers, and said that there was a need for more bee-keepers.

J. H. Bartlett, of Uintah County, said that the beehive in that locality had produced from a third to half a crop. They had no foul brood or other disease.

FOUL BROOD CURE—NEW METHOD.

The bee-industry in our State in this the beginning of the new century, although we have received some fairly good reports, on the whole they cannot be considered as good as might be desired; while in some of the southern counties the honey-flow has been unusually good, as also in some localities in the northern part of the State. The great honey-producers of the State, who are located in the central part of the State, which last year and some other seasons produced, in some instances, an average of about 300 pounds per colony, this year in the Uintah Valley district, yielded from about half a crop to a total failure. While there may be other reasons for this falling off, the principal one are drought, a lack of irrigation-works, disease, and a shortage of reproduction. In addition to this, in Salt Lake County, at least, is the smoker smoke; while in a few instances, in the best honey localities, the bee-keeper gets enough from his bees to make it profitable. The bees always die off through the fall from the effects of smoke settling on the bloom. We have been informed that one or more companies are going in to smoke-hunters this winter. We hope all will soon follow their example, as this question is getting to be a serious one to daryenists and farmers as well as bee-keepers.

But aside from the smoke, the grasshopper plague has been the principal cause of the destruction of the honey-flow and other crops in season. We call the attention of our bee-keepers, farmers and fruit-growers to this matter. It goes without saying that it should be plain to every thinking mind that some emergency measures must be taken to suppress this pest. In some portions of Salt Lake and other counties, the past season, the grasshoppers destroyed nearly everything that grew—potato, alfalfa and flax fields were turned into a shambles, and left to the ground. In the latter part of July I visited several orchards, and there was not a sign of a leaf left in them. Some of those trees will die, as the new growth of wood, together with the hark and buds of the small branches, are eaten off; and the alfalfa will die where it is eaten down into the crown of the plant.

Now for remedies that can be made effective on the effect of the grasshopper. Our friendly friends, the gulls, came and destroyed billions of them the latter part of July, but as they do not come until the breeding season, it is too late to do anything of value. The next best remedy which can be used when desired, are turkeys or chickens. While either can be made effective, the turkeys are not as efficient if properly hatched. Make a sufficient number of strong, portable coops that can be drawn where desired, and that can be closed so as to protect the birds at night. If the scheme is followed, it will not only serve to save the grasshopper pest, but it will prove a profitable business in raising the birds for the market.

There have been some experiments of late among the bee-keepers of trying to protect our bee-keepers and fruit-growers by destroying the moth and other destructive insects, the object being to reduce the number of the pest at the same time, without the use of a poisonous spray, which has not been, and will never be, a success in reducing the number of those destructive insects.

While it will be seen, from some of the reports sent in, this dearth of honey has been by no means universal over the State, if we can succeed along the lines indicated, we believe the old time prosperity will again be recorded generally. It is desirable, also, in that it would be beneficial to all concerned to have Colorado and Utah bee-keepers come in touch with the disposal of their products.

E. S. LOVESY.

Another method of catching grasshoppers is, in cutting lucerne, to leave a swath every two rods, on which the "hoppers" will congregate. Make a sack, out of ordinary cloth, about six or seven feet long and three to four feet wide, and attach the mouth of it to a wooden frame of the same size to keep it open. Then two persons on horseback drag the sack up and down the swath where the grasshoppers are—they jump into the sack and are caught. This sack can be used wherever it can be agreed among the farmers to be dragged only at night or early morning, as the hoppers then are not so easily frightened—they seem more stupid.

E. Johnson thought it would be a good idea to encourage buying supplies and in marketing bee-products. He also offered a resolution which carried, that the officers of the association make an effort to get the fraternal union with Colorado bee-keepers.

Mr. Carlson said he had lost his bees for several years on account of the smelter smoke. He purchased more, but they always died in the fall. He said but for the smoke his bees would otherwise be healthy.

J. Ferry said that nearly all the bees in that locality were dead; the smelters were about five rods away, and he had no doubt that the smoke from the smelters killed the bees.

Mr. Falkman, of Weber County, said that, taken as a whole, the bee-industry had not proven a success the past season.

J. H. Bartlett, of Uintah County, said that the bees in that locality had produced from a third to half a crop. They had no foul brood or other disease.
Another cure for foul brood is as follows: Take equal parts of carbolic and salicylic acids, saturate a flannel cloth and put it between two thin boards, so that the bees can not touch the flannel or acid. Put this in the place of center frame of the hive, removing the frames.

Mr. Gardner gave an interesting sketch of a bee-house 9x28 feet and 7 feet high, holding over 100 colonies. He manipulated his bees in the house, keeping them in winter and summer. He has three tiers of hives on each side of the house, running north and south. The house is built with tight board rustic. The hives are pushed up against the boards of the house, with the entrance opposite- facing holes in the boards. The walls are painted several colors, in perpendicular stripes, after the style of a barber pole, each stripe being the width of a hive. In this way the bees have no trouble locating their hives. He says the house has proven a success with him, the bees being easy to handle, with much less work, and his loss has, so far, not exceeded five per cent.

The honey crop in Uintah County was short, on account of a small, white, flying insect, the insect being very numerous in all necessary blooming during July. The pest made its first appearance July 1, and remained until the bloom was killed by frost.

Mr. Neilson gave a very interesting description of a moth-trap he has invented for the destruction of the codling moth and other insect pests. He stated that by this method the moth egg and larvae can be caught and destroyed at the same time, which makes it much more effective than spraying. He said the old-time poison spray had never been a success, and never could be, because of the large number of larvae caught—often not more than two per cent—and the harm done often exceeded the benefits derived. He was sustained in this view by several practical fruit growers present, some of whom said they had given up poison spraying as an expensive luxury, and not worth following.

Contributed Articles.

Long-Tongued Honey-Bees.

Read at the recent Colorado Bee-Keeper's Convention at Denver.

By PROF. G. P. GILLETTE,

of the Colorado Agricultural College, at Fort Collins.

Who first suggested breeding for long-tongued honey-bees, I do not know. It is said that a Mr. Wankler, of Germany, inventing an invention as early as 1882, for the purpose of measuring the length of bees' tongues. So far as I have been able to learn, the first person to bring this matter prominently before the bee-keepers of this country was Mr. J. M. Rankin, of the Michigan Experiment Station, at present the bee-keeper for the State. Mr. Rankin attempted to breed up a long-tongued strain of bees and believed that his efforts were crowned with some measure of success.

During the past year, or eighteen months, the subject of "long-tongued" or "red-clover" bees has been greatly agitated in the bee-journals of the country and has come to a veritable mind. A person having queens to sell feels that he is greatly behind the times—a sort of back number in this age of progress—unless he can guarantee his queens to produce a long-tongued variety of worker-bees. The result is, he so advertises them without knowing the real facts in the case, but with the belief that his bees have tongues as long as.

To a student of biology, particularly if he be an entomologist, the idea of a long-tongued race of honey-bees coming quickly into existence, seems extremely improbable. There is no more important organ in the anatomy of the honey-bee than its tongue for the maintenance of life, and nature has been breeding this tongue to a standard length for so long a time that it is not likely to vary rapidly under artificial selection where parents can be controlled on one side only. For these reasons the writer took no interest in the matter when it was first agitated. Finally, so many bee-keepers of known honesty and sincerity of purpose began to advocate breeding for long-tongued bees, and to advertise that they had such bees for sale, that it seemed necessary that some one, having the facilities and the necessary training, should make a careful study of the subject and report the facts. The writer began to collect bees for the purpose of testing tongue-length early last summer. It was not possible to spare a large amount of time for this purpose, but I feel warranted in making this preliminary report, and am expecting to publish a fuller one after continuing the work farther.

WHAT IS MEANT BY TONGUE-LENGTH?

The so-called "tongue" of the honey-bee is a very highly specialised organ made up of many parts. The longest single piece is the ligula, which is very flexible, yellowish in color, and thickly set with short hairs. Into this the nectar of the flower is first taken. It is supported by a black, rigid, chitinous piece called the mentum, which is about one-third as long as the ligula. At the base of the mentum is a still shorter piece which is also hard and rigid—the so-called "tongue-base." This is attached to the head by two slender, stiff rods, joined at the middle and known as the cardos or hinges. These medium parts with the attached portions (the two sets of palpi and the maxillae) make up the parts of the tongue. The important questions are, therefore, to determine how our base our measurements upon in giving tongue-length?

In breeding for long-tongued bees what one would want to know is the distance the tongue can be made to reach beyond the jaws or mandibles—the "tongue-reaching." As it is often called. This is the measurement which has been given us by Mr. Root and most others, so far as I know, who have reported lengths of bees' tongues.

Glossosimeters also have been constructed to measure this tongue-reach in bees, and in this case it has been found by Mr. Root, and others, that the tongue-reach of the bee is shorter than the tongue-reach of the mandibles, as the ratios between parts in a bee are far more constant than in man. For this reason, and for the further reason that it is more easy to get an accurate measurement of the parts of the tongue when it is dissected completely out and placed upon a glass slide under a compound microscope, I have considered the entire tongue-length the best measurement upon which to base conclusions as to tongue-reach.

I believe, for practical purposes, it may always be considered true that the bee with the longest tongue has the longest possible tongue-reach. As the man with the shorter arm-reach might suggest his patriotism from the tree than his longer-armed but less active brother, so the bee with shorter tongue-reach may excite her less industrious sister in collecting nectar from flowers.

In my first measurements tongue-length only was taken into account, but of the later ones the tongue-reach, so near as I could measure it, was also recorded. An examination of the figures in the following table will show a far greater variation in the latter measurements than in the former. If the tongue-reach should steadily increase when the long-tongued bee could usually increase it by two or three hundredths of an inch by a little careful stretching, I do not mean a real stretching, but a straightening of the joints of the cardos so as to extend the tongue-reach as shown in the illustration. The tongue will not remain in this position unless held there.

HOW TO KILL THE BEES.

Chloroform, alcohol, formalin, cyanide of potassium, and boiling water, were all experienced with to determine the
best killing agent, and it was found the last was the only one that would always leave the tongue in a completely relaxed condition for measurement. The water is first made boiling hot and then the bees are either thrust into the water or the water dashed upon the bees.

MEASUREMENT OF THE TONGUE.

To obtain the tongue-reach the head of the wet bee is removed and the tongue pulled out between thumb and finger as far as it will reach and pressed in this condition upon a glass slide with the face of the bee uppermost. The slide is then placed under the compound microscope and upon a rule graduated to hundredths of an inch, and the length of li gula, mentum, sub-mentum and total length read separately and recorded.

WHERE THE BEES WERE OBTAINED.

The bees whose tongues I measured have come from Maine to Texas in this country, and I have also had bees from imported queens from Germany, Italy and the Isle of Cyprus. In several cases bees were sent from the best and the poorest colonies in an apiary, and I took pains to obtain bees from those who were advertising long-tongued or red-clover queens. I have not asked permission to use the names of parties who were kind enough to send me bees, and shall not do so except in one or two cases, where I feel confident there could be no objection.

Photographing a Bee—How It Was Done.

BY W. W. WORKING.

READERS of the American Bee Journal may be interested in the story of the photograph as well as in the photograph itself; for it is no easy matter to pose a worker-bee just right and to get as good a picture of her as shown on the first page of this number.

Mr. C. Collier, one of the best photographers in Denver—Mr. J. C. Collier—who takes pride in doing difficult work better than anybody else, shook his head, and said it would be impossible to get the bee to sit still long enough to make a photograph. I insisted that I thought it could be done, and Mr. Collier said I. Mr. Collier's look convinced me of the stupidity of my question before he had time to frame an answer. How could he get the bee into focus? I supposed the thing was easy enough for a professional. But we took no picture that day.

When I called a few days later, the bees were shrunken corpses. "Too bad!" said the kind-hearted picture-maker.

I wanted a photograph. So a week or two later, I caught a few more bees and carried them to the studio. Mr. Collier said, "I just make a picture to get rid of me. And at the went!" He is a patient man: has photographed dogs, cats, horses, cows, and cross babies that had to be made to look sweet. The bee was worse than any of them. I wanted something more than a life-sized portrait—as the bee-keeper will understand from the engraving—and I got it, thanks to the patience and perseverance of the photographer. But the bee was dead before we got her posed just right, with that honey made so sweetly for all the facts. It is too long past, too strong in death. She was cross enough to look at before she died—poor thing—but it all came back in time to be caught, and forever impressed on the sensitive plate in the big camera.

In the end, the picture was taken by placing the bee between two plates of a studio, and then got a new plate—a ten-minute exposure. The result was better, but still not satisfactory.

Finally, after an exposure of seven minutes by the watch, the hard lines of the old man's countenance relaxed as he looked at the plate and said: "It couldn't be better—with such light as we have." So I was satisfied. Arapahoe Co., Colo.

**The Afterthought.**

The "Old Reliable" seen through New and Unreliable Glasses.

**SMOKING BEES—GETTING WORKER-COMB BUILT.**

Two ideas in Dr. Gallup's article, page 662, catch my attention. One is that frequent use of smoke makes bees cross. It seems to me that it must be a wrong reading of the facts that leads to that conclusion. Letting bees get the start of you undoubtedly makes them cross—and then your doing a lot of smoking, only makes them more so. Hence, it is not the use of smoke that is at fault, but the use of smoke with the mischief which the other circumstance did.

The other idea is moving outside frames into the center to have the comb built worker size instead of drone. I feel ashamed to confess that that almost makes me laugh. I have been working on an idea. It worked in this case, and very likely would work in most cases. It usually doesn't work to take out a center comb of a colony that swarms, and replace it by an empty frame; but that is a different affair. In hiving on empty frames and a self-farmer expects, he almost gets a frame built at all till during a strong flow they are wanted to store honey. This, of course, tends to drone-comb; while getting them built promptly, and in the center, would tend the other way, unless drone-broad was eagerly wanted.

**CABBAGES AND LEMONS.**

Cabbages two cents a pound and lemons one cent a pound, etc. Pretty good lecture on the law of demand and supply. Page 666.
FOLDED CHAFF CUSHIONS.

I can back up Mr. M. H. Hunt, page 668, that folded chaff cushions are a better fit than sewed ones—and also that they make holes in the latter after June perambulations. I hardly think the loss of the colony would always result from such attempt to swarm. I have all along thought the screen portico the best device for shutting up bees. Didn’t say much because top screens were so much more popular—and because I don’t perambulate, and therefore my own experience is very scanty. Glad to see Jacob Alpaugh, of Ontario, thinking somewhat as I do. Page 669.

SCREEN PORTICOES FOR HIVES.

So, with a big wire portico on the hives, bees think they can swarm, and sometimes try it and perish. Something of a difficulty to get the latter out of June perambulations.

SAFE INTRODUCTION OF QUEENS.

The A. D. D. Wood method of introduction is manifestly easier than caging an entire frame. I think we can accept it as nearly safe, seeing that he finds no failures. Of course, downy bees just emerged will not hurt the queen—and equally, of course, she will quit after awhile from “acting up” and provoking assault, if she has no bee of her own near her. I should not be surprised if this should turn out the most valuable practical kink which has been brought out for a good spell. Page 670.

ALSATIANS AND THE EXTRACTOR.

And so the Alsatians, at least some of them, think we invented the extractor—probably because they imported a good one from America. Page 676.

ANCIENT Temples EXEMPLIFIED IN COMB HONEY.

Mr. Ansell’s ornamental work in finished comb honey is quite a triumph in its line. Some of the first great and splendid temples that were built in the world were built in that form. Perhaps he had that thought in mind when he chose the form. Pages 673 and 676.

THE HIVE-KICKERS.

The hive-kickers seem to have had an inning at the conventional bee-keeper’s hive. The kicking bee-hive is all right if you do it in the right way—as Messrs. Kluck and Cogshall doubtless do. I suppose kicking King Edward in his palace would be all right, if you did it just right. Page 678.

Reversible Brood-Frames.

What do you think of the reversible brood-frames? How should they be used? Do you think they are of any advantage? Which is the best style to use? I have not seen anything said of them in the American Bee Journal.

Answer.—If you will turn back far enough you will find a great deal said about reversible frames in the pages of the American Bee Journal, as also in other journals. To day they are seldom mentioned. Quite a number of reversible frames were in existence, and there were also reversible hives, so that the frames could be reversed in a wholesale manner without opening the hives.

It was believed that when there was honey in the upper part of a brood-comb, reversing would make the bees carry up the honey into the super. While that result is generally achieved by reversing, there is found to be in the long run no special gain.

Another advantage was that reversing caused the bees to build their combs down to the bottom-bars. Either because that point could be gained in some other way, or because it costs more than it comes to, we hear nothing nowadays about reversing for the sake of getting frames filled out.

But the great thing that gave reversible frames and hives a real bonn was the belief that by their use we had a sure means of preventing swarming. It was claimed that when a queen-cell was turned upside down the bees would not continue it to completion. Then all that was necessary to do was to reverse often enough and no queen-cells would be sealed, therefore no swarming. Like many other things in bee-keeping, it worked better on paper than in actual practice; and it is also true that you can find any day who advocates reversing as a preventive of swarming. So it is hardly worth your while to try reversible frames.

Buckwheat—Sweet Clover, Etc.

1. Will buckwheat honey make suitable stores for wintering bees?

Answer.—I suppose that buckwheat honey was bad for winter stores, but later observations seem to show that it is all right.

2. I don’t know. One of the hardest things to find out about is the amount of nectar that can be obtained from a given area. If I should make a guess in the case, I should say that ten acres thoroughly covered with sweet clover might give profitable employment to 20 colonies of bees, but I’ll not quarrel with any one who says it ought to be three times as large, say, five times as small.

3. I don’t believe it will pay to rent land at $2.50 an acre to sow with any crop for the sake of the honey alone. But I may be mistaken about sweet clover. I do believe, however, that by taking a crop of hay from it each year it might be made to pay, the honey being so much extra.

Hive-Entrance in Winter—Keeping Combs of Honey, Etc.

1. In looking over the “A B C of Bee-Culture,” it advises leaving full width of the hive open for winter. I have mine reduced to ¾. I want to know if that is right.

2. I took off a shallow extracting super of 9 frames full of uncapped honey. I really don’t know what to do with it. I suppose it will sour before spring. I have one colony in a hive tiered up (2-story dovetailed hives), or rather a Dunz hive on the bottom and a dovetailed on top, with 9 brood-frames, each, full of honey.

3. I had two others in 2-story dovetailed hives and I put a bee-escape between them. Intending to take them off the next day, but other things called me away, and when I went back in a week the honey was uncapped and gone. The bees got under the hive-cover and cleaned it. Can you think of bee-escapes?

4. I don’t think there can be any queen in the brood-nest, as I have not seen any so far, although there is every evidence that there is a queen here. But I don’t know how to find her.

Honey from Prospects, Etc.

1. In case you will look to the “B C D” of Bee-Culture, it advises leaving the full width of the hive open for winter. I have mine reduced to ¾. I want to know if that is right.

2. I took off a shallow extracting super of 9 frames full of uncapped honey. I really don’t know what to do with it. I suppose it will sour before spring. Secured a Crop from Clover.
I secured a fine crop of honey from clover, but there was no fall flow except "just enough to fill the hives." Clovers, bearing ready at 15 cents — some sold at 20 cents the bushel near the fall. It has plenty of rain this fall, so we are looking for a good clover harvest next year. The weather has been exceedingly fine, and we have not put the bees into the cellar yet, but there is a change to-day, and I look for colder weather soon.

I have taken the American Bee Journal for over a year, and it was very helpful. I do not see how I could do without it.

Bert Gander.
Guthrie Co., Iowa, Dec. 1.

“The Proof is in the Eating.”
A Mr. Roegman visited me on some business the other day, and, on seeing the bee-hives made in and about my place, I got him the past season. On being told about $400 from 28 colonies, spring count, and an increase to 30, he could not help being pleased (as he got no honey at all); but on showing him the proof, and explaining that I was indebted to many bee-books and bee-papers which I was reading, and after offering to return him his dollar, if, after reading a year, he had not gotten his money’s worth, he decided to accept the American Bee Journal.

My bees are still on the summer stands, and have been flying nearly every day this month, though I think it has been detrimental to them. There has been but little brood reared since Sept. 15, and the wintering is going on.

F. W. Hall.
Sioux Co., Iowa, Nov. 29.

Experience with Honey-Plants, etc.
The past two seasons we have grown clover or Rocky Mountain bee-plant, as it was so highly recommended for bee-food—"fairly overflowing with nectar." We watched faithfully, but could never discover the bees at work upon the plants, nor near- ing. We have purchased, in a later section, however, in growing great quantities of Scabiosa, or "Mourning Bride," and in the latter, in the honey-cells, can strike bees around the blossoms from morning until late in the evening, and they also seem to revel among the clover, the egg-shaped flowers, or Bachelor’s Button, and Summer Sorcery.

We had a real fight the past season with the moth-millers—they never were so numer- ous. One colony was entirely destroyed in spite of our watchfulness. After opening a hive and destroying great numbers, in a few days they were all through the hive again. The robbing were also at work—bees killed and honey taken. How can we manage to save our bees from these pests?

Sarah A. Bowerman.
Monroe Co., N. Y.

Wintering Bees in Chaff Hives.
Bees in this locality went into winter quar ters with ample stores to last them until honey crops, or the clover plants we have been very fine the last week, thereby en abling the bees to have good flights, and to reach the waterings which comes the third or four days ago I noticed dandelions still in bloom. I am wintering a part of my apiary in chaff hives, where I have stories fed with chaff over the frames, and leaves on the chaff. Another portion is in the single-walled Simplicity hives, where we have paper clear around and over them, leaving the entrance so that the bees can get out when necessary. The tarred paper will keep off the snow and rain, and keep the wind from

Bees and Pear-Blight.

I see there is a good deal said about the pear-blight being spread by the bees. I have seen it on trees that had no blossom, so I would say that down here it is more on the water-sprouts, where there is no blossom, than anywhere else. My observation is, that if there is a freeze after the sap is up, there will be blight, bloom or no bloom; no freeze or chill, and there will be no blight. I believe this to be the prime reason of bigging would like to hear from others of the same opinion. I have noticed for several years that if there is no frost there is no blight. I like the American Bee Journal very much.

Dekalb Co., Terre., Nov. 23.

Report for the Season.

As it always interests me to read the reports of others, I take it for granted that they, also, bear of the success of those endeavoring to make a living through the agency of the busy bee. I secured 5,000 pounds of honey (1000 being comb) from 35 colonies, and increased to 65 the last season.

I have better success wintering my bees last winter than most apiarists in these parts, losing but 8 out of 65 (they having starved), when the average loss, so far as I have been able to ascertain, was 75 percent.

I put one colony on the scales last summer. It was fairly strong, and did not swarm. The following are their record:

Experience with Bees.

I came here in March, 1880, and commenced farming on a farm two miles from town. My father-in-law, Abner Bliss, had kept a few colonies of bees for years and was very successful. Mr. Bliss became very much interested later, however, and commenced studying the business to learn it rather perfectly. As for me, I have been interested somewhat in years gone by. During the winter of 1883-84, I had the privilege of foraging the acquaintance of Mr. A. J. Johnson, of Douglas County, who was a successful bee-keeper, and a reader of the American Bee Journal. If I remember rightly. There I saw a Langstroth hive for the first time, a foundation machine, comb foundation, a press for putting it in the hive, and many other things. I had a few colonies of bees at the time, and so became much interested, but lost them in 1886. I had a colony or two afterwards, but lost them, still I determined to try again.

Mr. Bliss told me if I would get a Danzenback hive he would give me a swarm to put into it. Accordingly, I sent for one and got it. The first colony had some surplus honey, but the other needed feeding, so I fed them and put them into the cellar, hung up a thermometer and kept the temperature correct through the winter. Mr. Bliss has practiced keeping bees in this cellar for some years with excellent success. When we took our bees out of the cellar last spring we found them in good condition, but the mice had eaten away some of the combs.

After I had secured a start in bees again I subscribed for the American Bee Journal, and Mr. Bliss has the “A B C of Bee-Culture,” and Doolittle’s “Scientific Queen-Rearing.” I have “Langstroth on the Honey-Bee Cook’s Manual of the Apiary,” and Newman’s “Bees and Honey.” And I read last winter.

Mr. Bliss bought 19 queens, and I 6; we then began making hives. We ordered sections and foundation, and I made the machinery for putting in starters, which is adjustable, and works with a foot-lever and an alcohol lamp. I believe it a success, and beats anything I have seen.

When our queens came we had two business at home, and I thought we were remarkably successful, but we do not know it all yet. I saved six queens out of six, and made some mistakes besides. We have learned something, and appreciate the assistance we get from the American Bee Journal and the books very much. Our honey yield for the past season was fair, and of very fine quality.

R. L. WILDSMAN.

Dec. 12, 1901.

AMERICAN BEE JOURNAL

Management of Foul Brood.

The Rocky Mountain Bee Journal is quite optimistic with regard to the management of a colony of bees. The Rocky Mountain Bee Journal is quite optimistic with regard to the management of a colony of bees. Mr. Bliss for producing honey and in case such a colony is affected with foul brood, saying:

Some of our largest and best comb-honey producers have for years made a specialty of producing honey. It is a well-known fact that section honey produced over brood combs is inferior in every respect; that produced over combs that are one year old, or older. In most localities there would be a big loss in having new bees work on the old combs every year. To one who has never tried it, such would seem to be the case in Colorado, but those who are practicing it assert that there is not only not any loss in the number of pounds of surplus honey produced, but an actual gain in the superior feeding quality of the honey secured, and the yield of wax from the old comb.

To secure new brood combs each season and not lessen the crop of surplus honey at the opening of the honey-flow, each colony is shaken into a new hive containing only foundation starts in the swarming condition ready to start the sections in the sections, building brood in the comb-bed only just fast enough to accommodate the material capacity of the queen. By the close of our honey season we have had brood combs to be filled, and the best possible work will have been secured in the sections.

To secure a success of any system, colonies must be strong, and the work must be done at exactly the right time. It may be said in its favor, that it effectually solves the problem of swarming.

Do Queenless Bees Prefer Too Old Larve for Queen-Rearing?

Last year I attempted to get an answer to this question. I think the result was conclusive. But Hon. H. L. Ford thought the position of the comb was such as to favor starting queen-cells from the younger brood. This year I thought I would make the test in such a way that no such objection could be made. At the same time I simplified the question put the bees, placing it this way:

“Which do you prefer, queen rearing, a cell in which an egg was laid not less than six days ago, or one in which an egg was laid not more than four days ago?” Or, assum

ing that the larva hatches from the egg in three days the question would be, “Which do you prefer, a larva three days old or one 24 hours old?”

July 16, at 10 a.m., I took from a nucleus the queenless colony an egg comb with comb we will call comb A. The queen in the nucleus had been laying about a week, and during that time, we had concluded that the comb could be morally certain that eggs had been laid just before removal. The comb was about two-thirds filled with eggs. I put it in an upper story of a strong colony over an excluder, along with other unsealed brood, which had been done in the same way. I fed the inner story, so that it would be well cared for.

July 10, at 10 a.m., I took from a nucleus (in which was my best queen) its two broodcombs, and gave it a comb that had not been used for queen rearing, but which had been used for a few cells of sealed brood, and its cells were well polished, ready for immediate use. This we called B.

July 22, at 10 a.m., I took from a full colony its queen and all its brood, putting in the center of the hive combs A and B, and filling

The Honey Bee

Revised by Daddant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to the American Bee Journal—Chas. Daddant & Son. Each subject is clearly and thoroly ex

plained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for $1.25, or club it with the American Bee Journal for one year—both for $1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with $3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

the preference, instead of their being content
with larvic so young as 24 hours. But their
general preference was for something younger
than the three-day larvie not onlj' younger,
but very much younger. Just one cell was
started with a larva as old as three days. One
can not b^ positive as to the age of that one,
but one can be very positive as to the other
2S.
July 24, when they were inspected, not a
larva on the comb could have been more than
three days old, as it is not possible that a cell
on that comb was at any time started with a
larva beyond that age. As they were all
started bet'urc 10 a.m. of that day, it is certain
that none of them could have been as much
as three days old, and probable that most of
them were much younger.
In

this case the bees
all

—

Some one may

ask, "

Why

are you so persistent in trying toshojv that the universally
accepted opinion Is wrong * What difference
does it make, anyway *'" The simple desire
to have the truth known ought to be incentive enough.
But there is something else that
makes it seem to me a matter of very great

consequence.
It is probable that not one in fifty of the
bee-keepers of the land takes the pains to use
the means that are now taught to be necessary to secure the best queens, using cell-cups

and that

sort of

thing.

Nor

will

they.

:

less bees prefer too old larvip cheats that man
out of the chance of easily improving his

stock.

He should

be told the truth in something

like these words:

"A

semi-annual meeting of
the Seneca County Bee-Keepers" Association,
will be held at the Bevier House, Romulus,
N.Y., Saturday, Dec. 14, 10(11, at 10 a.m. 1:30 p.m.
Hon. R. L. Taylor, of Michigan, will be present and address the meetiner. "Queen-Reariag"
discussion opened by Ira Wilson and C. J. Baldridge: ''Repairing Old Hives or Obtaining New
Ones," J. C. Howard and H. L. McLellan. Dinner will be served at the Bevier House, special
rates having been secured.

Fked
C. B.

HowAKD,

queenless colony will rarely,

if

ever,

prefer larv;t too old for good queens. None
of the most improved methods of modern
times will produce queens a whit better than
those the bees will rear in a colony you have
made queenless, so long as they have young
enough larva- to select from, .\tter the larvic
have become too old they may still start cells,
and these will produce poor i|ueens. If you
give to a nucleus or a colony two or three
good-looking cells, there is small chance of a
poor queen. Or you may give to the ([ueenless colony a fresh frame of brood and eggs
flveorsi.x days after being made queenless,
and then you need have no fear of poor cells
on any of the previous frames." Dk. C. C.
MiLLEii, in (Meanings in Bee-Culture.

CHAS. DADANT & SON, Hamilton, Hancock Co., Ill.

A New Bee-Keeper's Song—

"Buckwheat Cakes and Honey"

Words by EUGENE SECOR.
Music by GEORGE W. YORK.

This song was written specially for the Buffalo convention, and was sung there. It is written for organ or piano, as have been all the songs written for bee-keepers. Every home should have a copy of it, as well as a copy of

"THE HUM OF THE BEES IN THE APPLE-TREE BLOOM"

Written by EUGENE SECOR and DR. C. C. MILLER.

Prices—Either song will be mailed for 10 cents (stamps or silver), or both for only 15 cents. Or, for $1.00 strictly in advance payment of a year's subscription to the American Bee Journal, we will mail both of these songs free, if asked for.

Texas Bee-Keepers.

New Branch Office. We beg to announce the opening of a branch office and warehouse at 438 W. Houston St., San Antonio, Texas. Rates of transportation from Medina in less than car-load lots are high, and it takes a long time for a local shipment to reach Southern Texas points.

Low Freight and Quick Delivery—San Antonio. It has great railroads—the Southern Pacific R. R. east and West—the International and Great Northern R. R. from Laredo up through San Antonio and Central Texas, the San Antonio and Arkansas Pass R. R., and San Antonio and Gulf R. R. It also has the American, Wells Fargo and Pacific Express Companies.

San Antonio as a Shipping-point.

Our Managers. We have secured as managers Mr. U. D. Toepferwein, formerly of Leon Springs, and Mr. A. Y. Walton, Jr., both of whom are well known to the bee-keepers of South and Central Texas. They are also thoroughly familiar with practical bee-keeping and all matters associated with it, and any orders sent to this branch will receive prompt, careful attention.

Our Goods. As usual our motto is to furnish the best goods of the most approved pattern.

Our Catalog. We do not undertake to compete in price with all manufacturers. Bee-keepers have learned that it does not pay to buy cheap supplies, for a saving of 10 cents on the first cost of a hive may be a loss of many times this amount by getting poorly made and ill-fitting material. Every year brings us many proofs that our policy of "the best goods" is a correct one.

Our Invitation. Whenever you visit San Antonio you are invited to call at our office and make it your headquarters. Here you will find a display of Apicultural Supplies not curtained for sale in Texas. You will also find on file the leading bee-journals to pass pleasantly your leisure time.

Spanish Catalog. Some of you may read Spanish, or have a bee-keeping friend who does. If so, call for our Spanish catalog. It's sent free.

W. Z. Etchison, Secretary, Springfield, Ill.
A. L. Root, Treasurer, New York, N. Y.
E. I. Root, Corresponding Secretary, Cleveland, Ohio.

EXECUTIVE COMMITTEE.

Ernest R. Kerr, President, Chicago, Ill.
R. C. Aiken, Vice-President, Toledo, Ohio.
Dr. A. B. Mason, Secretary, Toledo, Ohio.

EUGENE SECOR, General Manager and Treasurer, Forest City, Iowa.

Membership Dues, $1.00 a year.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

Note.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to have one of the buttons as it will cause people to ask questions about the busy bee, and many a conversation that might otherwise have ended with the sale of more or less honey at any rate, it would give the bee-keeper a splendid opportunity to enlighten many a person in regard to honey and bees.

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

[This Cut is the Full Size of the Knife.]

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

HOWARD M. MELBEE.
HONEYVILLE, O.

Basswood Honey

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Alfalfa or Basswood Honey:
A sample of either, by mail, 10 cents, to pay for package and postage. By freight—two or more 60-pound cases of Alfalfa, 75 cents per pound; Basswood, 50 cents more per pound than Alfalfa prices. Cash must accompany each order. You can order half of each kind of honey, if you so desire. The cans are in two in a box, and freight is not prepaid.

Order the Above Honey and then Sell It.

We would expect that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

49 Please allow about two weeks for your knife order to be filled.
That Hoary Lie about the adulteration of comb honey seems still to retain much vigor. Here is a sample of its guiltlessness, kindly sent to us by Chas. F. Hoiser and others:

On my vacation in Michigan last summer I got some real honey—the real sweet kind, with a comb that choked up because it was so good. But I could not find it. Of course, every grocery store had what it said was strictly pure honey, in the finest looking containers; too nice looking; it was plain that it was all manufactured. A few days ago my grocer told me he had seen some real honey this time. I was certain of that, too, as soon as I saw it. I have worked with bees and know the cut-marks of their handwriting, and that comb was just irregular enough, imperfect enough in places to fool me. I bought two pounds. And when I got it home and took a mouthful the comb was not very sweet—it was a poor grade of glucose; and the comb melted in my mouth—l Volunteers.

No fading away of vigor about that, is there? Indeed, it has gained a robustness that exceeds its former self; for in former stages it only claimed that a minor part of the comb honey in Chicago was adulterated; now there is none of the genuine to be found in Chicago, although it be sought carefully for three months!

The amazing part about it is that this vigorous slander is not found in some obscure place, spoken by some ignoramus in the country grocery at the crossroads, but it is an opinion delivered in all seriousness before a body of supposedly brainy men. It is an extract from a paper read by the proprietor of the Farmer's Call, at the annual meeting of the National Agricultural Press League, and published in that sprightly periodical, Agricultural Advertising, published by Frank B. White Co., Mr. Frank B. White is well known as a man of unimpeachable reputation, and the soul of honor. Taken altogether, after so many years of battling with a great wrong, bee-keepers may be excused for feeling just a little discouraged as to getting anything like a semblance of justice.

More may be said of this hereafter.

Influence of the Queen. There has been some discussion as to whether the queen or the workers has the most influence upon the character of young royalty, some asserting that when black workers rear a queen from the egg of an Italian queen it would be the same as if reared by Italian queens, while others say the black nurses make of it a different being. Very far from this last view is that put forth in this country and in Europe, that a queen not only influences the character of her own offspring, but produces in some way, by her presence, a direct change upon the workers of another queen. The assertion is made that when the queen of a very cross colony is removed, and a queen of gentle stock introduced, not only will the colony be gentle when all the old workers have died off, but the crossness will all disappear within two or three weeks from the introduction of the new sovereign; in other words, while the bees of the cross colony are daily hatching out, and as yet there is not a single worker of the new colony.

As the newspapers say, "This needs confirmation!" and it would be well if those who have the opportunity would observe at what time a change of deportment may be seen when a gentle queen is put in place of a cross one.

Brood-Frame End-Spacers.—Opinions of bee-keepers are not so diametrically opposite as to many things as they are about the change made in frames which shortens the top-bars and depends upon staples driven into the end-bar to hold the frames in place lengthwise. Some claim that the change is a real boon. The bee-space at the ends of the top-bars prevents deposition of glue at that point, making it much easier to handle the frames. Others say the staples are constantly driven in and, as soon as driven in far enough there is the worst kind of trouble. The difference in the thickness of top-bars or end-bars may account for the difference of opinion. With a top-bar less than half an inch in thickness, and a 1/4-inch end-bar, the staple will not be firmly held, and will soon be out of place. With a thick end-bar, or with a top-bar so thick that the staple will be driven through the end-bar into the top-bar, there ought to be little or no trouble.

A Swarming Story.—The following has been sent to us as the report of something remarkable:

A Bee Story. James D. Noeland, an 80-year old farmer of Pike township, has had an unusual experience in his apiary this month.
The Buffalo Convention.

(Continued from page 900.)

FEEDING BEES FOR WINTER.

"Would heavy candied combs of honey alone, be safe to winter bees on, or cakes of candy alone, be safe, without any combs of honey?"

A. I. Root— I think the most successful feeding I did was with cakes of combs and I have leftover cake cakes on colonies in the fall with almost no combs at all, and laid cakes of maple sugar over the frames and wintered them all right. I think there is a good deal of difficulty about wintering bees without combs; if the candy gets damp and sticky, the bees will stick to it and will die, and if they get the dysentery they will die. Candied honey is not exactly satisfactory, but sometimes it will answer. In sugar feeding, sometimes the sugar comb in the combs, and I have known the bees to let a lot out on the bottom and then seem to die for want of moisture. The difficult thing is to furnish enough moisture along with the feed. I am here in New York State where you have colonies by the hundreds or thousands you cannot bother with candied honey. Maple sugar is a very poor thing to build up colonies where they are short of stores. I put it on the fall and left it on all during the winter, and in the spring when they have been short of stores I have put it over the frames to stimulate them. One of our most successful bee-keepers in Ohio wrote to me that she had 50 or 60 colonies of bees and they did not work but she used cakes of maple sugar and put over the combs, and she said that she had one of the biggest yields that they had in Ohio. She attributed it to the maple sugar, but it needs watching and care.

BEE-STINGS AND THEIR REMEDIES.

"What can we do if badly stung? Should every bee-keeper have a bottle of ammonia? How is it administered? What is to be done to a horse when badly stung?"

W. L. Coggshall—I never had any horse stung.

Mr. Niver—I cover up so I don't get stung.

W. L. Coggshall—I feel as if I had been very successful in that line. I have handled a good many bees and we haven't had any accidents yet.

A Member— My mother was very badly stung all over, when she hived a swarm of bees, and they gave her salt and water to keep the poison from her stomach as much as possible, and we saved her life, but I don't know if it was done by a professional nurse.

Mr. Alpaugh—I have a remedy from an outsider that doesn't keep bees, that is a complete one, which is simply a little coal-oil.

Mr. Baldridge— My son was stung when very much heated, just under the chin, and so much affected that he swelled all over. We sent for the doctor at once, but before he arrived my son vomited and the swelling went down at once.

Mr. Longmecker— A remedy which I have seen used is to bathe the part with a strong solution of ammonia. It is very cooling and satisfactory.

Mr. McEvoy— The doctors generally recommend aromatic spirits of ammonia, half a teaspoonful; and if it doesn't work in a few minutes don't wait long—repeat it.

Dr. Mason—I believe that whiskey is better than ammonia.

Mr. Fuller— My remedy is chloroform. Just a few whiffs inhaled always relieves me.

SECTION SIZE—BLEACHING HONEY.

"Which is preferable, the 4", or the 4x5 section?"

Dr. Mason— That depends upon locality.

"Can extracted honey be bleached? If so how?"

W. J. Craig— It can be improved. We have had extracted honey exposed in a room where the sunshine could penetrate and we found that the honey in which we had exposed in that way was much lighter within a week than the same honey which was confined in a dark place. We put it in 5 or 10 lb. cans.

EXTRACTING HONEY—COMB HONEY GRANULATING.

"In running for extracted honey, should one spread the combs, and then when uncatching cut deep?"

W. L. Coggshall— I spread six or seven combs and uncatch them evenly.

"What is the cause of comb honey in sections becoming granulated soon after being removed from the hive, or much earlier in the season than in former years, in some localities?"

Mr. Fuller— My experience is with comb honey, if you will keep it at a temperature of about 92 to 95 degrees it won't granulate.

COM-BEE HINTS.

"What strain of bees is the most profitable for comb honey?"

Mr. Alpaugh— I would say a good cross between Italian and a black. Blacks are very good of themselves, but I don't like them, for the reason that they are a little awkward to handle, but I do think that a good cross between an Italian and a black would be all right.

Mr. Baldridge— I like good yellow-colored Italians for all purposes.

Mr. West— The best that I have seen
for the past two years was a cross between the Carniolans and the Italian.

Huber Root—I have found a cross between a Carniolan and an Italian a good cross.

Mr. Fuller—I can get the best results by having full-blooded Italian queens and let them mate as they please.

Mr. Greiner, chairman of the committee on the score card, then handed in their report, but not being quite completed it was left in the committee’s hands to be completed and forwarded to the secretary.

Mr. McEvoy moved that the report be adopted as read. Mr. Smith seconded the motion, which was carried.

The convention then adjourned to meet at 8 p.m., at the Epworth Hotel, in Joint Session with the American Pomological Society.

(Continued next week.)

The Illinois State Bee-Keepers’ Association met at Springfield, Nov. 19 and 20, 1901, and was called to order by Pres. J. Q. Smith. The forenoon session was mostly spent in visiting and getting acquainted, except the usual preliminaries—secretary’s report, and reports of committees.

The afternoon session was called to order by Vice-Pres. S. N. Black.

Dark Uncandied Honey.

“What is the dark mixture in honey that does not candy?” was asked. It was too hard a question to receive an answer till Mr. Smith came in. He said his bees stored quite a lot of that kind of honey one year, and he found, on the alighting-board, dead from the milk-weed, and there was a great field of the weeds in full blossom; and he found his bees working on it strongly.

Mr. Black—I have seen bees fastened on milk-weed blossoms, and dead.

Mr. Smith—That honey did not candy.

Fertilization of Worker-eggs.

Geo. Pointmesser had illustrations of his own pointing in evidence of the Wagner theory of the fertilization of the worker-eggs, and not of the same for the drones. He thought the theory was correct.

Mr. Black did not think the theory was correct, as he had seen where the queen had laid fertile eggs in cells so near the edge of the comb as not to have depth enough to cause the contraction of the queen’s abdomen in depositing them; others had seen the same thing.

Honey-Dew, etc.

“Is there such a thing as real honey-dew, aside from the so-called ‘bug-juice’”?

Many illustrations were given to prove that there was, and it was unanimously decided that there was real honey-dew honey, and that of good quality.

“Do bees always select their place of destination before swarming?”

Arguments were advanced to prove both sides, and the question is still open for argument. Mr. Black cited a case where bees surely went 20 miles across a prairie.

Second Day.

The meeting was called to order by Pres. Smith, and a discussion was opened on the premium list. Mr. Black moved that the executive committee, which is the President, Secretary and Treasurer of the Association, be made the premium-list committee, and that the revision of the same be left to them.

Carried.

Mr. Becker moved that the meeting proceed to election of officers for the ensuing year, which was carried, and resulted as follows:

President—J. O. Smith; 1st Vice-Pres.—Miss E. C. Kennedy; 2nd Vice-Pres.—S. N. Black; 3rd Vice-Pres.—A. N. Draper; 4th Vice-Pres.—George Pointmesser; 5th Vice-Pres.—J. E. England, Secretary—Jas. A. Stone, R. R. Springfield; Treasurer—Chas. Becker.

Cellar Wintering of Bees.

“Is it best to put bees into the cellar in this latitude?”

Several said no, not if well protected.

Mr. Smith—I just take slats out of the super, cover the brood-frames with a piece of gunny, then fill the super with dry leaves, and I never lose any.

Longer-tongued Bees.

Mr. Draper—“Do we need longer-tongued bees?”

Mr. Black—Yes. The reason our Italians store honey from red clover is that our soil is so worn that it does not produce clover-heads as large, with as deep cups, as it did old.

Secretary—I think the whole cause is that they are apt to be too far apart. When the cups are open so that they reach the nectar just as easily in the largest heads as in the small ones. I have watched them and seen them go as readily to the largest heads as to any other.

Mr. England—I think we need longer-tongued bees.

Messrs. Smith, England and Poin- messer reported good crops of honey this year.

The executive committee chose for the date of the meeting next year, the third week in November, Tuesday and Wednesday, the 15th and 19th.

On motion the convention adjourned.

JAS. A. STONE, Sec.

Contributed Articles.

No. 4.—Apiculture as a Business.

By R. C. Akin.

I have previously referred to a fact which I think is generally conceded, that alfalfa is a slow yielder of honey, and, so far as I know, I have never seen a bee with a plump pellet of alfalfa pollen. I think if bees were to depend upon alfalfa pollen they would starve, if a lack of it would starve a colony. In my locality there is never a superabundance of it in my locality—and this is true of many other Col- orado fields, and at times there is a dearth of it both in and out of the hives.

Pollen, in early spring, has much to do in the matter of building up a colony, and leave them in good condition when the flow comes. Here, there is no pollen in the fields until about April 15, nor is there much, often none, in the hive, either. To supply the need, bees are greedy for anything in the nature of flour, getting into chop-feet bins, into horse feed troughs, mills and granaries, in fact wherever any floury substance is found. I have seen them raking dust out of rotten wood, sawdust, and such. Unless the matter is looked after, by manipulating, this is what happens with bee-keepers who are not apiculturists.

There is also a considerable part of the spring up to June to 15 in which there is no nectar coming in. I call attention to these facts to show that it is business to look after the bees, instead of leaving the hives in the hands of an apiculturist, who is not in the habit of making money on his bees.

Pollens are often the most difficult things for the average apiculturist to manage. Having failed to get as many bees as might have been obtained, the flow begins with weak colonies. Supers will be put on, but work will not be begun in them, and apiculturists—or rather, bee-keepers—wonder why the bees are not doing much. They are looking the brood-combs with honey, and while the queen wants to lay freely she cannot, because she has no more empty comb in the brood-chamber, and they go about with sacks full of honey, secreted wax freely, start queen-cups, feed their limited amount of br.; I freely, queen lays in the queen's hive.
Moving Bees Short Distances.

BY C. P. DARANT.

WOULD it be safe to move 20 colonies of bees now, or would it better be delayed till pasture is wanted? I gave two moves only 20 feet north and 20 feet east.—John T. Pattin, Johnson Co., Iowa, October 17, 1903.

As there are many such enquiries, I will give my manner of moving bees, and the reasons for it, in more detailed form than in the private reply I gave to Mr. Pattin.

When we move our bees, we must bear in mind the instincts and habits of the worker-bees. At its first flight, out of the hive, the young bee takes a survey of its location by flying in circles slowly and carefully, evidently to examine all surrounding objects, and these first flights of young bees, which always take place early in the afternoon of a warm day, are well known to apiarists, because usually several hundred, and sometimes several thousand, bees thus take flight almost at the same moment. The beekeeper, and those who regard the bees that circle about to recognize the spot where they have found honey. But the robber-bee is restless and hurried, and, to a certain extent feels ashamed and acts more or less sneakingly, while the young bees have a contested, peaceful flight, like a selection of a young whose conscience is at ease, and whom nobody pursues.

At the second flight, the young bee still looks about, but with much diminished care, as it feels more sure of its location. After that, the worker-bee strikes out like an arrow, without looking behind. Its flight is quick, and natural, and the result is that the expression, "take a bee-line," is equivalent to saying, "take a straight, short course over hills and valley."

When we move our bees it is important that we should remember this. If the hives are moved during cold weather, so that the flight of the bees is interfered with, this may cause the slight disturbance; or, if we move them during warm weather so carefully that they do not realize that anything is wrong, we may very positively expect that when they issue out of the hive they will do as usual—take a bee-line without stopping to look back. If the hive has been changed in position a short distance, they will vainly seek it on the old spot, and will wear themselves out in a short time, unless one of the hives is in a reasonably disturbed condition, when some bees may find it and will attract the others by the drumming of their wings. But many will get lost, and if the wrong hive is entered many will be killed.

If, on the other hand, we take pains to let the bees know that the hive is being moved, by closing up the entrance and leaving it closed quite a while after the hour when they might take flight during a fairly warm day; if we handle the hive somewhat roughly while they are thus confined, and do not release them till they have all been warned that something is wrong; if we also give them a few puffs of smoke when releasing them, and if they are enabled to take flight at once, and look over the ground, it is quite likely that the most of them will fully realize the fact that their location has been changed, and we may rely on their natural intelligence to find the spot again. And many of the bees do not take flight at once, even after a rough shaking up, it is well to leave with them a reminder of their change of location, so that when they, the bee goers, start out, they can have the true facts, and not things that are not what they were. This reminder we put in the shape of a board leaned up against the hive, in front of the entrance, so that the bee may be prevented, at the start, from flying in a "bee-line" toward the field. This obstruction, of course, causes the worker to look back and investigate, as soon as on the wing, and the new location is thus more sure of being noticed.

Yet in spite of all these precautions, some bees may have authority to fly off at will, and the plans before given is not fail absolutely if any empty hive or box is left where their home stood. Should any great number thus congregate, they may be given to one colony at night-fall, and with this colony they will be sure to remain.

But if the above-given instructions are carefully followed, no bad results need be feared. As a matter of course, this evidences the necessity of moving the bees at a time when they can still fly, and during such weather as will not be likely to chill them if they remain longer than usual on the wing, as
American Bee Journal

Dec. 19, 1901.

This letter is conclusive as to the method I recommend. It has been tried many times, but the latest testimony is always the best.

Hancock Co., Ill.

Swarming—Eucalyptus Trees—Ball ing Queens.

BY DR. E. GALLUP.

The remarks of Mr. E. E. Hasty, on page 633, seem to call for something more from me. I had to cut down four eucalyptus trees and move three colonies—one 12 feet, one 25, and one 34. The first two I shook into the clustering box early in the morning, before the bees were out to work; the last, from the very strong colony, and I did not get it until afternoon, consequently a strong force was out in the field. Of the first two, not a bee went back to the old stand; the other kept coming in until nearly night, but I learned the lesson after getting all the clustering bees and shutting them up. There is a big swarm of the bees has about, finally clustering in it, when I carried them to the new stand and shook them in front of their hive; the following day not over half a dozen bees returned to the old stand. It was a novel sight to see from two to three quarts of bees together, and nearly every one loaded with different-colored pollen.

The Eucalyptus Tree.

Now, a little about the eucalyptus tree. Eight years ago last July I set out 80 small seedlings, and now one of the four I cut into stove-wood measures 12 inches across the stump, 12 inches from the ground, the tree measuring 80 feet in length. The eucalyptus blossoms from December to March, so the bees are humming on it all winter. I have often wonder ed if the leaves do plant disease or not. They are self-irrigating after the first season, as the leaves condense the moisture from the atmosphere at night, and one often sees puddles of good size under the trees in the morning, after a rain. Eucalyptus always get wetted with a pall the first season, soon after they were set out. Eucalyptus makes the best of fire-wood, and if cut in the winter the stumps send up sprouts from 8 to 15 feet in length the first season. The leaves and twigs make the finest kind of kindling for starting a fire.

Mixed Swarms Ball ing Queens.

Mr. Hasty may be right about a lean honey-flow, but I have succeeded here and in Iowa, and will give my experience.

In Ventura County, last morning, a large prime swarm issued and clustered in a big live-oak tree. I cut the limb and let it down to within four or five feet of the ground and fastened it there. I then shook the bees into a clustering box and carried them to the hive to have the queens. While doing this, out came all after-swarm and clustered on the same branch. Well, I soon had fun enough, for I had 14 or 16 (I have forgotten which, it is so long ago) swarms come out, and sometimes three or four clusters in one. They all clustered on the same branch, but as soon as I would see a great rush to the cluster I would shake them into the box, and from that into a hive placed on the cover, and then closed the hive with a quilt or blanket to keep out the swarming bees. After the

American Bee Journal

Questions and Answers

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Jour-nal office, or to Dr. Miller direct, where he will answer them. Please do not ask the Doctor to send answers by mail.—Editor.)

Rearing the Best Queens.

Can we not get a long-tongue bee, healthy bee, ambitious worker—and all of these considered good and useful qualities—by some one that can control the mating fairly well? Breed, or mate, the queen with the drone from her sister worker? It looks to me as if there would be a gain of at least one-half of a bee-generation, in the preservation of the good qualities of the workers.

ANSWER.—The project of having some one make a business of rearing queens on a large scale in something like the way you mention has had some consideration; but as yet nothing has come of it. It is true, however, that some able men are interested in rearing queens, and it is a ground to try to bring up to the requirements you mention, and there is constantly approach to the highest standard being made.

Starting with Bees.

I would like directions for a beginner to start with bees in the spring; in northern Indiana. I know nothing about bees. How should I proceed in order to insure the best success. Please give explicit directions.

I. G. NORANCE.

ANSWER.—I don't know. I'd give a good deal if I did. I've been trying for years to learn just what is the very best way to do it—sure success, but I'm not always sure of success. Sometimes the season is so bad that I can lay my failure en-
tirely at its door. Sometimes I get a notion that some new way will be an improvement, and it turns out so poorly that I wish I had not tried it. So large has been our progress, to tell you just what I think I would do if I were to begin all over again.

The first thing I would do would be to get a good textbook and study it with care. In that you ought to find much or all of the "explicit directions" you ask for. Then if you expect to go into bee-keeping somehow or in some way, it will be well to get another textbook and study that. Also read with interest what you find given weekly in the American Bee Journal, and perhaps in other journals. Thus you can spend a very profitable time in learning the business and be prepared to care for your bees than you are now. In the course of your readings you will find some things hard for you to understand. After you have puzzled over them a reasonable length of time, write for an answer in this department. Don't be afraid to ask questions. That's what this department's for. But there are two kinds of questions that may well be for you to steer clear of.

One kind of questions to avoid is the kind that you find fully covered in every textbook. Such, for instance, "Do the drones lay eggs?" "How long is it from the time the egg is laid till the young worker hatches out?"

The other kind of questions to avoid is the kind that is too comprehensive, including those that expect an answer without giving particulars. In this category would come the question: "Give explicit directions for getting a big crop of extracted honey." "What is the reason my bees stored no honey this year?"

When spring opens up, and you begin work with the bees, keep referring to your textbook, and keep asking questions. I'll try and find answers for all that are not too hard.

Moving Bees in Winter.

I expect to move 150 miles west about December 20, and want to take my 45 colonies of bees. I expect to charter a car. Can they be moved successfully at that time? IOWA.

ANSWER.—Something depends on the weather. If it should be exceedingly cold, the combs will be brittle, and there will be danger that some combs may be broken. I can give you little light additional to what you find in the books, the chief points to look after being: To have the frames stationary in the car; to have plenty of ventilation (although much less ventilation is needed than in hot weather); and to see that the hives are loaded into the car so that the ends of the frames point toward the engine.

Wintering Bees in the Cellar.

I put 30 colonies of bees in the cellar this fall, raising them one inch from the bottom-board. I put burlap over the frames, and Supers without the slats, filling them with chaff. For ventilation I left the covers off. Is this a good way? WISCONSIN.

ANSWER. — The preparation you have described is all right, and is a good deal more preparation than many feel necessary, for bees will winter well with the covers sealed on when there is plenty of opening below. Read carefully what your bee book says about temperature and ventilation of the cellar.

Feeding Bees.

When, and what and how can I feed my bees? I have two colonies of Italians, and have had them about eight months. I get lots of literature from the American Bee Journal and it seems to be for advanced beekeepers. IOWA.

ANSWER. — This department has its field and its limitations, and it is not hard to account for the fact that some things will not be found in it, nor indeed in any part of the Journal. There are some things—many things—which every bee-keeper should know when he begins the business. If these things were told in these pages, it would take several numbers, without leaving room for anything else. By the time they were all told a new set of subscribers would want the whole again, and another set of subscribers are coming in all the time the American Bee Journal would be entirely occupied printing over and over again the same things. To avoid this, instruction books or text-books on bee-keeping have been published, and one of the first things for busy bee-keeping to do is to get one of these text-books and become familiar with its contents. After he has done this he will find plenty of questions still that he would like to ask, and the very fact that there is no need to repeat the things in the textbook makes him feel as if he were more fully upon any point not fully treated in the textbook.

Upon consulting your textbook you will find that the best time to feed bees is much earlier in the year than December; and that the best thing to use for feed is combs of sealed honey and the best place to put them directly in the brood-chamber, in or close to the cluster of bees. Of course, much minute information is also given, which would occupy pages, and after you have studied it all carefully it is quite possible you may desire light upon some of it. The columns are freely open to answer any further questions you may have. If your bees do not have enough to carry them through the winter, combs of sealed honey may be yet given, the best thing being candy.
verses urge grandly to just this blessed life of forgiveness. I wish all the children of our great country might learn the great sermon teaching was spoken from the Mount. As also Romans 12th, and 1st Corinthians 13th. The last is our college chapter here at Pomona College. If we could all learn those chapters, and catch practically their spirit, how quickly we would solve not the only question of anarchy, but of all sin and evil.

One in our large class said, “If kind when the desire to be forgiven was shown?” I did not admire his words or spirit when he replied to the question, “What will bring the sorrow for sin and a right repentance so quickly as to be engulfed in the arms of love?” I might put on any arm about a human doer, but I would keep the other ready for other and possible wise use.” This remark leads to our second topic.

TRUST AND CONFIDENCE.

If we are foolishly, as voiced in the arm ready to strike, we shall never win. If we trust our children; our students, if we are teachers; our neighbors; if we show a kindly confidence we will find them slow to betray such trust. We must keep the confidence of all these; we can not expect what we do not give.

Jacob died. The brothers remembered their grievous offense—their awful sin toward Joseph—they were afraid. With no occasion they suspected Joseph. He was full of sadness the day he was spoken from the Mount. Hi lack of trust, confidence, and belief in one’s integrity of purpose from those we love? In age such a sorrow would press hardest. And so Joseph met life’s evening hour with a real heart burden. What a woeful arrayment of evil? It companions with distrust and suspicion, and thus it weights heavily even the best and truest friend.

SPORTS.

To-day our college is to meet on the football field the Indians—a very noted side of Indians who can play football. For years we have not lost a game. Last year we met this same team and vanquished them with a score of 16 to 0. This year we are stronger, yet we are not sure. When ye think ye stand, take heed lest ye fall.” Last night we all students and faculty—held in the gymnasium a meeting to arouse enthusiasm, and give courage to the team, whom all believe in. We know they have practiced hard. We expect they will win. The team expects to win. We expect as we know they will; we all feel confident. Even the girls are keenly appreciative of good, honest, work as a bright, witty speech from one last evening evinced.

A professor spoke. He showed that one ought not to become so old that he would not find play-sport a pleasure. He found when his son was rounded up, when a rival from harder, truer work has won a right to victory. All applauded, but the cheers rang out with merrier, louder note when he added, “but we do not expect defeat. Your hard, telling work makes us all very expectant. We shall encourage the games, and all pure, honest athletic sports. None who do not reach high grade in studies can take part in the games. We believe these contests are good and helpful, and that they make better, stronger men.

IS PERFECTION DEMANDED OR EXPECTED?

I have received the following from one of the American Bee Journal subscribers. For reply in this department:

On page 682, Prof. Cook, in discussing the matter of voting the prohibition ticket, says: “God does not demand perfection in any of us. ‘Only one, your Father in heaven, is perfect.’” I do not know who is the author of the words quoted by Prof. Cook, and I do not undertake to dispute them, but I do know that it was the great Preacher in his sermon on the mount who said: “Be ye therefore perfect, even as your Father which is in heaven is perfect.” I say, “Be ye perfect,” to tell me, is just much short of perfection is demanded of me. If I understand him correctly I am not required to do all I can to kill the saloon, but may stop short of voting against it. But I would like to know whether the requirement comes from God. Encourage him to do that which will prevent me from taking a glass now and then.

Imperfection.

I am glad “Imperfection” makes these inquiries. His very name shows that he sympathizes with my position. One said to Christ, “Good Master,” He answered, Cali not me good. Only one is good, your Father in heaven. Yet, this same blessed Savior said, “Be ye perfect even as your Father in heaven is perfect.” I hope I am wrong, but from my own experience from Paul’s words “When I would do good, evil is present with me.” From all my observation from the whole trend of the Scriptures, I am led to question the possibility of a perfect life in this world. Did not Christ, in his “Be ye perfect,” mean to give us this as the ideal? Maybe very late in life, just at the margin of the river, some are so happy as to reach this ideal. I trow, however, that it only comes as we rise to another side.

Are we not happier as we strive harder to reach the ideal? To let go this effort would only mean less of joy, less of satisfaction. “Imperfection” would find no relief in any abatement of effort. Our joy doesn’t come that way. We are all—required to do all in our power to kill the saloon, and any other damnable evil. But it is not my duty to condemn you if your method and mine are not the same. If all the good and the true are in the Prohibition party, then surely, we are, in sorry plight. I do not believe all the wisdom is there. Does “Imperfection?”

THE EMERSON BINDER.

This Emerson stuff-bound binder with cloth back for the American Bee Journal we mail for 60 cents; or we will send it with the Bee Journal for one year—but for only 3$00. It is a nice thing to preserve the copies of the Journal through the years. If you want this “Emerson” so further binding is necessary.

**REVERSIBLE WALL MAP**

**OF THE UNITED STATES AND WORLD**

WITH SPECIAL INSET MAPS OF

China, Cuba, Porto Rico, The Philippines, Hawaii, and Alaska,

Especially prepared to meet the demand for a first-class map that will give a quick, general idea of location of events the world over, and particularly to the United States and our territorial possessions. Very useful in every Home and Office. 66 x 46 INCHES IN SIZE.

ELEVEN BEAUTIFUL COLORS.

Best and Most Necessary Map Ever Issued. No Home or Business House should be without it.

The Plates

are works of art. The engraving is plain, bold, and decisive. The color work is elegantly contrasted, but not gaudy.

Perfection and Artistic Elegance

a salient feature of this map not approached by any similar publication.

It has been pronounced a Photograph of the World

The 1900 Census of the largest American Cities is given.

One side shows a grand map of our great country, with counties, railroads, towns, rivers, etc., correctly located. The other side shows an equally good map of the world. Statistics on population, cities, capitals, rivers, mountains, products, business, etc., a veritable photograph of the UNITED STATES AND WORLD.

The map is printed on heavy map paper and is mounted on sticks ready to hang. Edges are bound with tape.

1904 EDITION. Every reader should consult it every day. The plates show all the new railroad lines and extensions, county changes, etc. Special attention is given to the topography of the country; all the principal rivers and lakes, mountain ranges and peaks are plainly indicated. The leading cities and towns are shown, special attention being given to those along lines of railroads. The Canadian section of the map gives the provinces of Ontario, Manitoba, and British Columbia, with nearly all of Quebec and New Brunswick, the county divisions being clearly marked. The Southern portion of the map includes the Northern States of the Republic of Mexico, and the Bahama Islands.

On the reverse side is the Library Map of the World. The largest and most accurate map on Mercator’s Projection ever produced. The political divisions are correctly defined and beautifully outlined in color. The ocean currents are clearly shown and named. Ocean steampship lines with distances between important ports are given. A marginal index of letters and figures enables one easily to locate every country in the world. A series of short articles in alphabetical order is printed around the border of this map in large, clear type, containing valuable information concerning agricultural, mining, and manufacturing statistics, also the value of imports and exports in dollars. The area, population, form of government, and chief executive of every country in the world is given up to date, also the names of the capitals and their population. The Inset Maps are elegantly engraved and printed in colors. They are placed in convenient positions around the United States map, and will be invaluable to every person desiring a plain understanding of our possessions. An inset map of China on the World side of map adds to its value.

Two maps forward it free as a premium for sending as Three New Subscribers at $1.00 each; or for $2.00 we will send the Map and Address,

THE AMERICAN BEE JOURNAL  
AND THE OHIO FARMER.

Both Papers One Year Only $1.50, or with Ohio Farmer TWO years only $2.00.

A 32-page, 8-column weekly, with the best staff of editors and correspondents; a strong, fearless defender of the farmers' interests, and clean in both reading and advertising; for the farmer. Send to Ohio Farmer, Cleveland, Ohio, for free sample copy, but send all subscriptions to GEORGE W. YORK & CO., 144 & 146 Erie Street, CHICAGO, ILL.
American Bee Journal
Dec. 19, 1901.

main honey mouth. I had but a few colonies, and about one-fourth as much honey as the previous season. I have some black, some hybrid, one Italian, and two Carniolan colonies. The blacks gave me no surprise at all. I bought an Italian queen last year, and that colony produced three or four times as much honey as any of the rest, with the exception of five or six out of about 80 colonies. They gathered some honey nearly as bright as castor-oil; I never saw anything like it before, and do not know what was the cause of the increased production. Most of my bees spent the season rearing queens, I think. I, for one, do not want my queens clipped. I am a farmer, and cannot be here all the time. If the queen can fly they will settle and wait till I come home. If they are clipped they will come out and go back before I can get there. I lose one now and then, but I like them to be able to fly. I have just read Mr. A. E. Hors's report in the American Bee Journal for Nov. 21, in which he mentions his having a sour smell. I notice it here every year, I think, but I do not know what causes it. Bees gather bitter honey here nearly every fall, but none of mine ever candles.

Several bee-keepers have asked Dr. Miller about late drones this fall. My bees reared a lot of them very late. I like it was because they had a very good flow of bitter honey.

This is my first year with Carniolan bees, and I do not know whether I will like them or not. Although fully 95 percent of the untested queens he sent out were purely mated, next season all that he mails for us will be warranted purely mated.

We want every one of our present subscribers to have one or more of these money-maker Queens. We have received most excellent reports from the queens we supplied during the past season. And next year our queen-breeder has had a great account of rain. I thought fully 95 percent of the untested queens he sent out were purely mated, next season all that he mails for us will be warranted purely mated.

Orders for these fine, "long-reach" Warranted Queens will be filled in rotation—"first come, first served"—beginning as early in June as possible. It is expected that orders can be filled quite promptly (even better than the past season), as a much larger number of queen-rearing nuclei will be run. But never remove the old queen from the colony until you have received the new one, no matter from whom you order a queen.

All Queens will be guaranteed to arrive in good condition, and will be clipped, unless otherwise ordered.

A Warranted Queen for sending us Only 2 New Yearly Subscribers

In order that every one of our subscribers who wants one of these Warranted Queens next season can easily earn it, we will bid a year's order for one queen for sending us the names of two new subscribers to the American Bee Journal and $2.00. Furthermore, we will begin to send the Bee Journal to the new subscribers just as soon as they are received here (with the $2.00), and continue to send it until the end of next year, 1902.

So, forward the new subscriptions soon—the sooner we send out the much copied copies, the more we receive.

This indeed is an opportunity to get a superior Queen, and at the same time help swell the list of readers of the old American Bee Journal.

We are now ready to book the Queen orders, and also to enroll the new subscriptions. Remember, the sooner you get your order in the earlier you will get your Queen next season, and the more copies of the Bee Journal will, the new subscribers receive the sooner you send it in. We hope that every one of our present readers will decide to have at least one of these Queens.

*The Honey-Bee*  
*Revised by Dadant—1900 Edition.*

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son.

Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for $1.25, or club it with the American Bee Journal for one year—both for $1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with $3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

and I am still getting orders for more, and I didn't have to advertise, either. I was out on the mountains last week on a hunt, and shot a very fine doe that weighed, dressed, 103 pounds. It was the first deer I ever saw, and I shot it from a distance of 12 yards.

I have seen so much discussion about roofs of late that I would like to say a word about covers. There is no flat cover in this country that will stand without warping or checking. I cover all my gable covers with red rosin paper and paint them, and make the gable covers by taking a 6-inch board for the ends, then cover with shingles and paint, for flat top and weather, then cover all the rest over flat cover, allowing it to extend two inches at the ends and sides. My colonies are always dry and nice. They are cooler in summer and warmer in winter, and the cost is only a trifle.

Clearfield Co., Pa.

**BEE-BOOKS**

**NEW POSTPAID BY**

**George W. York & Co., Chicago.**

**Bees and Honey,** or Management of an Apiary for Profit and Pleasure, by Thomas G. Dadant.—It is nicely illustrated, contains 150 pages, beautifully printed in the highest style of the point of view, bound in cloth, at $1.30. Price, 50 cents, in cloth, 75 cents; in paper, 50 cents.

**Langstroth on the Honey-Bee,** revised by Dadant.—This classic has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth, the Father of American Bee-Keeping. It has 520 pages, bound in cloth. Price, $1.25.

**Bee-Keeper's Guide,** or Manual of the Apiculture, by Prof. W. L. Hutchinson.—This book is not only instructive but a guide in bee-keeping is interesting and thorough and practical and scientific. It contains a full delineation of the anatomy and physiology of bees, 460 pages, bound in cloth and fully illustrated. Price, $1.25.

**Scientific Queen-Rearing,** as Practically Applied, by G. M. Doolittle. A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, $1.00.

A B C of Bee-Culture, by A. A. Root.—A cyclopedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 350 engravings. It was written especially for beekeepers. Bound in cloth, $2.50.

**Advanced Bee-Culture,** Its Methods and Management, by W. L. Hutchinson.—The author of this work is a practical and entertaining bee-keeper. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

**Rational Bee-Keeping,** by Dr. John Drierzon. —This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, $1.50.

Bienen-Kultur, by Thos. G. Newman.—This is a german translation of the principal portion of the book called "Bees and Honey." 60 pages, pamphlet. Price, 25 cents.

**Bienenzucht and Honiggewinnung,** nach den neuesten methoden (German) by J. F. Eggers. This book gives the latest and most approved methods of bee-keeping in an easy, comprehensible style, with illustrations to suit the subject. 50 pages, bound cover. Price, 50 cents.

**Bee-Keeping for Beginners,** by Dr. J. F. H. Brown, of Georgia. A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 100 pages, bound in paper.

**Bee-Keeping for Profit,** by Dr. G. L. Tinkler. A practical and enlarged edition of the author’s “new system, or how to get the largest yields of honey.” 80 pages, illustrated. Price, 25 cents.

**Dr. Howard’s Book on Foul Brood.—**Gives the McKown Treatment and reviews the experiments of others. Price, 25 cents.

**Winter Problem in Bee-Keeping,** by G. R. Pierce.—Result of 25 year's work. 30 pages.

**Foul Brood Treatment,** by Prof. F. R. Cheesman.—Its Cause and Prevention. Price, 10 cents.

**Foul Brood,** by A. R. Kohnke.—Origin, De-velopment and Cure. Price, 10 cents.

**Capoa and Caponizing,** by Dr. Sawyer, Fanny Field, and others. Illustrated. All about capoa and how to use it, and thus how to save the most money in poultry-raising. 64 pages, Price, 25 cents.

**Our Poultry Doctor, or Health in the Poultry Yard,** by C. F. Howard.—Contains the best of Fanny Field.—Everything about Poultry Diseases and the Treatment of Them. Price, 50 cents.

**Poultry for Market and Poultry for Profit,** by Fanny Field.—Tells everything about Poultry Business. 64 pages. Price, 25 cents.

**GIEDEER’S FINE CATALOGUE**

of fine wading pasture for 10c, printed in 40c, illustrated and contains 40 Varieties of Fowl, given reasonable prices of eggs and seed. Many photos to show what the birds look like. Also, good Prices for hens, ducks, geese and turkeys.  

310F18 Mention the American Bee Journal.
The "Barler Ideal"

OIL-HEATER....

Saves Its Cost Every Year!
NO ODOR! NO SMOKE! NO ASHES!

Costs only a cent an hour to run it.

The editor of the American Bee Journal is using the "Barler Ideal" Oil Heater, and it is all right in every way. We liked it so well that we wanted our readers to have it too, so we have recently arranged with its manufacturers to fill our orders. The picture shown herewith is the one we recommend for general use. It is a perfect gem of a stove for heating dining-rooms, bed-rooms, and bath-rooms. It hinges luck in a substantial way, and is thoroly well made throughout. The urn removes for heating water. The brass fount, or well, has a bail, and holds nearly one gallon of kerosene oil. It is just as safe as an ordinary lamp. You wouldn't bewithout it for twice its cost, after once having one of these stoves. Most oil-stoves emit an offensive odor, but this one doesn't. Its height is 2½ feet, and weighs 50 pounds, or 30 pounds crated ready for shipment, either by freight or express.

Price, f.o.b. Chicago, $6.00; or, combined with a year's subscription to the American Bee Journal—both for only $6.50. FULL DIRECTIONS GO WITH EACH STOVE.

If you want something that is really serviceable, reliable, and thoroughly comfortable, you should get this "Barler Ideal" Oil Stove, as it can easily be carried by any woman from one room to another, and thus have all the heat you want right where you want it.

A HANDY TOOL-HOLDER!

Sent by Express, for $1.50; or with the Bee Journal one year—both for $2.00.

Every Manufacturer, Miller, Carpenter, Cabinet Maker, Machinist, Wheelwright and Quartermaster, Farmer, or anyone using a grindstone, should have one of these Tool-Holders. One boy can do the work of two persons, and grind much faster, easier and with perfect accuracy. Will hold any kind of tool, from the smallest chisel to a draw shave or ax. Extra attachment for sharpening sloyd blades included in the above price. The work is done without wetting the hands or soiling the clothes, as the water flows from the operator. It can be attached to any size stone for hand or steam power, is always ready for use, nothing to get out of order, and is absolutely worth 100 times its cost.

No farm is well-equipped unless it has a Tool-Holder. Pays for itself in a short time.

How to Use the Holder.

Directions.—The Tool is fastened securely in the Holder by a set-screw and can be geared to any desired level by inserting the arm of the Holder into a higher or lower notch of the standard. While turning the crank with the right hand, the left rests on an steadies the Holder; the Tool is pointed for the right or left across the stone, or examined while grinding, as readily and in the same way as if held in the hands.

For finding Round-Edge Tools, the holes in the standard are used instead of the notches.

Mr. B. H. Greider, the well-known poultryman of Floria Pa., a regular advertiser with us, is now ready for distribution. He is one of the best books of its kind, and is beautifully illustrated in colors. It describes all varieties of prize-winning poultry, with a great deal of interesting and valuable information on poultry topics. It is worth a great deal more than the ten cents in silver or stamps asked for it. Address, B. H. Greider, Floria, Pa., and mention the American Bee Journal when writing.
CONVENTION NOTICES.

Wisconsin.—The Wisconsin State Bee-Keepers’ Association will hold its semi-annual convention in the city of Milwaukee, on Wednesday, Feb. 6, 1903. This promises to be a large convention. All are invited and encouraged to attend. The general subscription rates of 1½ for the round-trip, good for one year, have been announced. N. E. FRENCH, Pres.; ADA L. PICKARD, Sec.

Michigan.—The Michigan State Bee-Keepers’ Association will meet in convention at Petoskey, Jan. 1 and 2, 1903. This promises to be one of the largest meetings. All are invited and encouraged to attend. The general subscription rates of 1½ for the round-trip, good for one year, have been announced. N. E. FRENCH, Pres.; ADA L. PICKARD, Sec.

California.—The California State Bee-Keepers’ Association will hold its annual convention in the Chamber of Commerce, Los Angeles, Janu-ary 15 and 16, 1902. We will try to have a good pro- gram. Come and exchange your bright ideas with your neighbors, and get some of the most intelligent, well-informed men, and attend.

R. A. BURNETT & CO.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Dec. 7.—The honey market is of a slow nature with little change in price of any grades. At the close of the week the sellers of the retailers have laid in a supply sufficient to carry them over the holidays. Choice grades of white honey is 14½c. a pound; dark grades, 13¼c.; light amber, 12¼c.; dark grades, 11¼c.; brown, 9½c.; and 5c.; and 5c.; the scale of prices varying according to color, body and package.

R. A. BURNETT & CO.

NEW YORK, Dec. 9.—Honey continues to be sold at demand prices. At the close of the week, with the exception of the heavy strawberry, all grades of honey are slightly lower, and the demand is still as heavy as it has been all winter. The honey market is rather scarce. We quote: Fancy white, 15c.; No. 1, 14c.; No. 2, 12½c.; and buckwheat, from 10½c. to 10c. Extracted remains dull and inactive with plenty of supply of all kinds. Inquiries for white and dark honey are still numerous, and the winter demand is heavy. The market is in good condition.

CINCINNATI, Oct. 25.—The honey market is rather dull. Some demand for light honey is noted. Extracted sells only to manufacturers from 7c. to 8c. a pound. White honey, 10c. to 12c.; white clover, 9½c.; white clover, 8c.; and buckwheat, 10c.; white honey, 14c.; buckwheat, 12½c. Extracted, white, 6c. and 7c.; mixed, 6½c. and 6c. H. W. HARRISON.

OMAHA, Oct. 25.—New honey is coming. It is reported that it is the best honey to be seen here for a long time. It has a large, honeycomb, and the honey is of a rich color. It is available in good supply at prices ranging from 10c. to 12c. per pound, f.o.b. Cali-fornia. The market for buckwheat is also in good condition. The demand for buckwheat is also good and the price is steady at 12½c. per pound, f.o.b. California.

PICKY BROS.

BOSTON, Nov. 20.—The demand for honey is on the rise. The market is in good condition and the supply is ample for the holiday season at which time it is much neglected. Our market at the present time is in the hands of producers. We have quoted $5 per pound, f.o.b. California, for strictly fancy in cartons: No. 1, 14c.; No. 2, 13c.; 12½c.; Extracted, light amber, 75c.; and 5c. H. W. HARRISON.

DES MOINES, Oct. 25.—There is very little doing here, because there is a very scarce crop of honey. Some small lots have been bought by the retailers and selling in a retail way at $1.50 to $2.50 a pound. They are all in good condition in this line before Sept. 1. Our market does not consume a great deal of extracted honey.

PICKY BROS.

DETROIT, Nov. 25.—Fancy white honey, 14½c.; No. 1, 13½c.; no dark to quote. Extracted, white, 6½c. BEEWAY, 2½c. M. H. HUNT & SON.

SAN FRANCISCO, Nov. 24.—White comb, 11½c. per pound, f.o.b. California; 10½c. Extracted, white, 5½c. to 6c.; light amber, 4c.; and 4½c. Beeswax, 6c. to 8c. Beeswax is not doing much in this center, but there are no large stocks here of any description, and current values are being maintained. There is more moving outward at present. The German honey is not in much demand here. Some apiculturists are reporting holding back supplies, anticipating better prices in the spring.

PICKY BROS.

KANSAS CITY, Oct. 25.—Up to the present time only a small lot of some honey have been seen on the market, and most of it being for sale on the basis of 15½c. per pound for fancy and 12½c. for comb. For next season's various expected and quotations are set at $3.10 per cent for large lots, which would be equal to $3.75 per pound. A few outside parties have been heard from, and it is believed that a firm market is anticipated. Inquiries for extract are on the increase. Many of the large and small buyers still seem to have their ideas too low. In a small way $6½c. is quoted.

PICKY BROS.

**A NEW BEE-KEEPER'S SONG—**

"BUCKWHEAT CAKES AND HONEY"

Words by EUGENE SECOR.
Music by GEORGE W. YORK.

This song was written specially for the Buffalo convention, and was sung there. It is written for organ or piano, as have been all the songs written for bee-keepers. Every home should have a copy of it, as well as a copy of "THE HUM OF THE BEES in the APPLE-TREE BLOOM"

Written by EUGENE SECOR and Dr. C. C. MILLER.

**PRICES—** Either song will be mailed for 10 cents (stamps or silver), or both for only 15 cents. Or, for $1.00 strictly in advance, payment of a year's subscription to the American Bee Journal, we will mail both of these songs free, if asked for.

**NEW BRANCH OFFICE.**

We beg to announce the opening of a branch office and warehouse at 438 W. Houston St., San Antonio, Texas. Rates of transportation from Medina in less than car-load lots are high, and it takes a long time for a local shipment to reach Southern Texas points.

**LOW FREIGHT AND QUICK DELIVERY.**

San Antonio as a Shpping-point.

Our Managers. We have secured as managers Mr. Udo Toepperwein, formerly of Leon Springs, and Mr. A. Y. Walton, both of whom are well known to the bee-keepers of South and Central Texas. They are also thoroughly familiar with practical bee-keeping and all matters associated with it, and any orders sent to this branch will receive prompt, careful attention.

Our Catalog. Very few changes in prices will be made in our new catalog, so do not delay your order, but send it at once. You will be allowed a refund if lower prices are made, and in case of higher prices ruling in the new catalog, if any, you will secure the benefit by ordering now. Catalog and estimates may be had by applying to the address given below.

Our Invitation. Whenever you visit San Antonio you are invited to call at our office and make it your headquarters. Here you will find a display of Aparian Supplies not equalled elsewhere in Texas. You will also find on file the leading bee-journals to pass pleasantly your leisure time.

Spanish Catalog. Some of you may read Spanish, or have a bee-keeping friend who does. If so, call for our Spanish catalog. It's sent free.

MEMBERSHIP DUES, $5.00 a year.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his celler-label. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to try with one of the buttons as it will cause people to ask questions about the honey and many conversations thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper an opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a plaza on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

HOWARD M. MELBEE, HONEYVILLE, O.

(The cut is the full size of the knife.)

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the knife is placed the name and residence of the subscriber, and on the other side picture of a queen, drone, and worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the handle is made of celluloid spring-steel, and the finish of the handle as described above. It will last a lifetime, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise they will try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your Pocket-Knife will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side.

The accompanying cut gives a faint idea, but cannot convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for $1.25, or give it as a Premium to the one sending as a gift the first new subscriber to the Bee Journal (with $5.00). We will club the Novelty Knife and the Bee Journal for one year, both for $1.50.

GEORGE W. YORK & CO. St. Chicago, Ill.
The Annual Index will be found in this issue of the American Bee Journal. As many readers preserve every number, the index will be found very valuable thing. In fact, if there were nothing else in this copy but the index, it would still be worth a good deal, as it shows the wide range of apiarian subjects treated in a single year.

Breeding from the Best has been the motto for so long a time, that when F. E. Simpson advocated in the Bee-Keepers' Review that a queen of very exceptional qualities being in the nature of a freak could not be relied upon to reproduce herself, therefore it was better to breed from a queen whose progeny were only a little above the average as to results, but showing greater constancy in her royal progeny—when Mr. Simpson advocated this doctrine, it seemed a little like the explosion of a bomb-shell. No one has proved that Mr. Simpson's position is wrong, and yet the fact remains that good results have been obtained—or at least seem to have been obtained—by following the old rule, to breed from the best.

Mr. Doolittle says in Gleanings in Bee-Culture that he has followed that rule for 30 years—breeding always from the queen that gave workers most valuable in bringing in nectar from the fields, rather than from those of the most uniform markings or purity, mentioning especially one remarkable freak from which he reared nearly all of his queens as long as she lived. Not only has his average yield per colony increased, but the uniformity of yield from his colonies has been constantly on the increase.

Comb Honey by the Case.—On another page, Mr. D. W. Working, the secretary of the Colorado Bee-Keepers' Association, has a reply to both the recent article by R. A. Burndt & Co. and our editorial on the same subject.

We fail to see how Mr. Working can expect to convince any one that it is a fair way to sell honey at wholesale by the case—simply lump it off—instead of by weight. We wonder if he'd like to buy coal in that way—by the box full—may be box even full and shaken down, and may be not.

But the straw man estimates only a single generation of drones, whereas there may be two or more generations, although all the drones are not allowed to live five weeks. A considerable amount of honey should also be figured in what is used to feed the drone-brood.

Injury to Queens in the Mail is a subject of some discussion in Gleanings in Bee-Culture. Two of the somewhat numerous Miller families are not in entire accord as to the reason why it is that after a queen has been sent through the mail she will sometimes “go bad,” although having been all right before being mailed. Arthur C. Miller says the trouble is that the queen has suffered for want of proper nourishment. He says:

Remember that a queen in the full exercise of her functions is developing two and a half times her own weight of eggs every 24 hours. It is not the sudden taking of the queen from a place in which to deposit her eggs that injures (for she can and will continue to extend them as they develop), but it is the lack of sufficient proper food to restore the drain on her system. If such food is not available in sufficient quantity she starves, and on the duration of such starvation depends the extent of injury to her vitality. Knowing these things, and knowing that a queen free in her hive can ask and obtain food from thousands of bees, it is irrational to believe and assert that she will die when compelled to depend on twelve bees, only a few of which may be able to supply her needs. These statements may be readily verified by any one who cares to take the necessary pains.

Dr. C. C. Miller thinks that when a queen heavy with eggs is put in the mails, her great weight is such that is from not hold on to her place, and is injured by severe concussions. He suggests the advisability of caging a queen 24 hours before mailing, so that she will not be so heavy.

Whenever one is right, or even if both are right, might not the previous eaging be a good thing? If the trouble comes from starvation, because the queen demands such a large quantity of food, then it is not a matter of the queen ought to help, for after 24 hours cessation of laying she would not demand so much food.

Educating Tastes in Animals.—At the Chicago convention there was a decided difference of opinion as to the looking of stock for sweet clover, some saying that cattle would not eat it, and others saying they would eat it greedily. Both were no doubt correct, the fact being that there is more than is generally supposed in the matter of having the taste educated. With no thought of reference to sweet clover, A. I. Root, in Gleanings in Bee-Culture, tells about poultry having educated tastes, so that they greedily ate raw beans.

It is also said that Texas cattle that have never eaten corn will refuse to eat it at first. It is well known that cows in a state of nature are quite dainty in their tastes, yet the family bossy may be trained to eat almost anything, including dishwater. If sweet clover hay be fed dry, it will in many cases be accepted more readily than the green fodder, and perhaps in all cases a little persistency may succeed in having stock eat sweet clover either green or dry.

The Laws of Breeding, it is pretty safe to say, have never before had the attention they are having from bee-keepers and
queen-breeder to-day. At least, there never was much attention given to the subject at the present time in the bee-papers. Doubtless much more would have been written and known about the subject if the matter of bees could be controlled as in the case of other animals. It is at least within the range of possibilities that the Order of Fratellini may yet become an accomplished fact, and if it ever does come it will be well to be prepared for it. Even if we never reach any greater control than at present, a thorough knowledge of all that can be learned about breeding may be turned to account. Especially let the younger members of the fraternity inform themselves as fully as possible on the subject that may be interesting, and sometimes controversial, may be found in the bee-papers, but carefully study and take up that science which is so useful in leading toward improvement of our present stock of bees.

Weekly Budget.

APRIL OF R. WHEELER.—On the first page of this number is the picture of the apiary of R. Wheeler, of Alameda Co., Calif. It is located on the slope of a hill, and is a model apiary, showing all the hives but one. In the further right corner is a nucleus hive, containing four 3-frame nuclei, under the same roof, where he boards his spare queens. To the left will be seen a shade-roof made of shingles 3 feet long, nailed to strips of board 2 by 3, in number. It hangs on a pivot outside the hive, as shown in the picture. By throwing forward it gives room to work at the hives, changes the shade, etc. In front of the hives is a coat-sash. Between the two pieces of old boiler-tinling is planted nigmondote and primrose. The hydrant and hose are in the near right corner. All is enclosed by a wire fence 3 feet high. It is a very neat apiary.

BRITISH ESTIMATE OF AMERICANS.—It is very pleasant to know that a very kindly feeling exists between this and the mother country, especially among beekeepers. W. W. Staden, a prominent British beekeeper, who has spent some months in this country, writes to the British Bee Journal:—

‘I feel convinced that we have a great deal to learn from our American cousins. They are a progressive people, and are fast coming to the front in almost everything. The evidences of progress throughout the country, and especially in the cities, have simply amazed me. Many of the American beekeepers’ methods and appliances are unsuitable for adoption in England, on account of climate and weather conditions, but there are others that ought certainly to be valuable to us, and it is to be hoped that our people will give the matter a fair trial, so that we may not lag behind the times.’

Mr. Frank Rauchfuss, the energetic and wide-awake manager of the Buffaloo Bee-Keepers’ Association, was in Chicago a few days last week. He had been visiting various cities in the interest of his Association, which will doubtless result in mutual benefit. We had several good visits with Mr. Rauchfuss. So did Mr. Burnett, of R. A. Burnett & Co. Of course, the subject of hive-blower by case so well was discussed quite thoroughly, and we think Mr. Rauchfuss returned feeling that there is more than one side to it.

The Buffalo Convention.

THIRD DAY. EVENING SESSION.

The meeting was held at the Epworth Hotel, and was called to order at 8 p.m., by Mr. Watrous, president of the Pomo logical Society, who announced that one of the papers set down for the afternoon session, and which had not been read at that session, would be read then. After the reading of the paper, which offered no practical interest to beekeepers, President Watrous said:—‘We have with us to-night the National Bee-Keepers’ Association, and their report. I think the paper which has been read may have provided a series of discussions here which we shall next have, and without further preliminaries we will now listen to Mr. James Fletcher, of Ottawa, Ont., Canada.’

Prof. Fletcher then delivered the following address on the subject of Bees as Fertilizers of Flowers.

At the last annual meeting of the Ontario Bee-Keepers’ Association, I had the pleasure of delivering an address on ‘The Value of Bees in Fruit Culture.’ On this and other subjects, I discussed the burning question of whether bees did or could injure the fruit-growth by attacking sound fruit on the trees. The position I took at that time was that unless fruit was first broken or injured, honey-bees could not gain access to the juice of the fruits. It appears to me now, however, that the ability of bees to puncture ripe fruit need not take up so much discussion at a beekeepers’ meeting as has on some occasions been given to the matter.

If it is so very doubtful whether they can or cannot cause injury, it seems prima facie evident that even if it is possible—which I do not believe—the injury occurs so seldom that it need not be considered. If it were a frequently occurring or important injury, some of those who have watched bees would have been able to settle the matter long before this.

Another subject taken up by me at the time referred to was, ‘Bees as Fertilizers of Flowers,’ and at the request of President Root, of the National Bee-Keepers’ Association, I have prepared a paper for reading on this subject at the meeting on that subject, in which I shall direct your attention to the striking interrelation of plants and insects, and in which I shall draw to your attention facts which may be new to some of your members, must be of interest to all, and cannot but call forth admiration for the marvelous provisions which are to be seen everywhere in Nature for the bringing about of good and useful results and preventing waste. It will be found that not only are flowers absolutely necessary to bees, as the source of nectar and pollen—but that bees and other insects are no less necessary to most flowers, so that their perpetuation may be secured.

This fact should be recognized by the fruit-grower, above all others, for were it not for insects, and particularly for the honey-bee, his crops of fruit would not be seen at all. A single flower consists of two sets of organs—a protective envelopment made up of the corolla, as a rule, of a fruit which prevents insects from working actively in the flower, than to any other cause. Flowers of plants are a special development shoot for pollination, and apart from the flowers of plants are many small parts called stamens and calyx; the former of these represent the male sex, and the latter the female. The anthers—the important part of the stamen—are practically small cases containing pollen, without the agency of which the ovules or undeveloped seeds which are needed in the fruit of the pistil cannot come to maturity, or—from the fruit-growth’s point of view unless the flowers on his trees are fertilized in this way, no fruit will form, and his labor will be in vain. It is necessary that pollen should be applied to the stigma or sensitive portion of the pistil before the seeds can be developed, and it has been found that R. It is most advan tageous to a species that the seeds of a given flower shall be fertilized by the pollen from some other flower of the same species.

A study of the devices provided by Nature to ensure this cross-fertilization forms one of the most charming branches of the whole study of biology. It is a branch of the subject which may be said to have had its origin in the remarkable investigations of the great naturalist, Charles Darwin, and has since been developed in Europe by Lubbock, Anton Kerner, and Miller. In this country excellent work has been done by Messrs. Halsted, Bailey, Roberts, Waugh, and others. We are with you to-night, so that it will be seen that the study itself is quite recent, but,
now that attention has once been drawn to it, it can be recognized as a garden feature, for the flowers of these plants have been used from the beginnings of gardening, and are always of greater benefit to their descendants for flowers to be fertilized by pollen from other flowers of the same kind growing upon other plants. He seems to have arrived at this trite observation, “Nature abhors perpetual self-fertilization,” which was first enunciated in his great work on the botany of orchids. The publication of this classic work marks the beginning of one of the most important eras in the history of the science of botany. Since then endless observations have confirmed the accuracy of Darwin’s law, and it has been found that in the vast majority of plants special appliances exist which will secure a more or less frequent inter-cross, and that in many these appliances completely exclude the possibility of self-fertilization.

The cross-fertilization of some plants is ensured by the male and female organs of the same flower coming together, or by those of flowers on the same plant or the same tree, and some flowers by those of flowers on different plants. In the case of the flowers of the same plant or the same tree, the male and female organs coming to maturity at different times, sufficiently far apart for it to be impossible for the pistil to be fertilized by the pollen borne on the same flower. In many cases there are remarkable contrivances which prevent such fertilization, as in the flowers of many species of plants.

In the case of plants of the same species, the male and female organs coming to maturity at different times, sufficiently far apart for it to be impossible for the pistil to be fertilized by the pollen borne on the same flower. In many cases there are remarkable contrivances which prevent such fertilization, as in the flowers of many species of plants.

stems, particularly around the flower-stalks. In some plants, as the fuller’s teasel, the leaves join around the stem, forming a sheath which catches rain and dew and forms an insuperable barrier. What is also doubtless a provision for the protection of the seeds of plants is the fact that the flowers of many plants can be damaged by animals or insects; it will frequently be noticed that the blossoms themselves are seldom destroyed. This may be due either to a more abundant production of thorns or bristles around these organs, or that they are rendered distasteful by certain compounds which are more abundantly secreted by them.

This fascinating branch of my subject is far too wide for me to more than refer to it now; but I am convinced that the adornment of every part of a plant has some special significance if we can only discover it. That we have not yet perceived of what advantage these are, by no means justifies us in assuming that no advantage exists, and the search for the meaning of the innumerable shapes of flowers and leaves, their positions and behavior under varying circumstances provides a limitless source of pleasure and valuable instruction to whomsoever takes the trouble of making a lifelong study of each observation and exercising every care not to be carried away by the subject and jump to conclusions.

I have with me here today some excellent charts made by my friend, the Rev. Thomas Fyles, of Quebec, the president of the Entomological Society of Ontario. These will enable me to illustrate some of the points I have referred to, far better than I could otherwise have done. JAMES FLETCHER.

Some fine, colored charts were here exhibited, and much information was given about each in turn. Some of the points explained, were as follows:

No. 1.—POLLEN-GRAINS.—Although so small, the minute pollen-grains are of exceeding interest, as their surfaces beautifully ornamented in a variety of ways. In fact, these minute objects are just as characteristic and easily recognizable under the microscope as are the different kinds of seeds. The pollens of several well-known plants were shown, as illustrative of the different shapes and markings of pollen-grains, of pine trees, which is very light, is produced in enormous quantities, and when carried on the wind and deposited at a distance, forms the basis for showers of powdered sulphur. An instance of this was brought to his notice during the past summer at Armstrong, in British Columbia. A remarkable occurrence for the extreme likeness of the pollen-grains of pine trees was one of these so-called sulphur showers on the deck of a ship nearly 200 miles from the coast. The captain of the ship, who happened to be a botanist, detected the true nature of the yellow deposit by putting some of the material on his microscope and finding that it was pollen.

No. 2.—MOUTH-PART OF THE HONEY-BEE, the bumble-bee and the wasp.—The differences in the mandibles of these insects were pointed out and explained. The mandibles of the honey-bee are provided for the working of wax, and this only when softened at a high temperature. Those of the wasp for gnawing wood for the manufacture of the pupal cases, with which their nests are surrounded.

No. 3.—FLOWERS OF THE PEA FAMILY.—These were illustrated by figures of the Broad bean, showing the distinct contrast of black and white, the Sweet pea and the Broom. The different structures were explained in their bearing on the question of cross-fertilization, attention being drawn to the brush-like stigma and the keel.

No. 4.—FLOWER OF THE SUNFLOWER FAMILY.—The many points of interest of these flowers, and the devices by which they are prevented from becoming self-fertilized, were explained.

No. 5.—FLOWERS OF THE COMMON PIMPERNEL, referred to above, showing the two forms with long and short pistols.

No. 6.—FLOWER OF TROPICOLUM.—Attention was called to the markings and tufts of hair in the throat of the garden flower known as the Nasturtium, which acts as path-finders to insects of a proper size and shape, so as to secure fertilization to the seeds when they visited the flowers for the sake of the copious nectar in the long hours.

FLOWERS OF ANTSIRIHNUM.—The necessity of a large, strong insect, such as a bee, to open the Snap-Dragon flower and reach the nectar was evident, but it was stated that certain ants do this work. One example of this is the direct entrance to the nectar at the base of the flower. After this entrance was once made, honey-bee might be prevented from finding flowers through this hole instead of entering by the proper opening. This Mr. Fletcher believed was an analogous case to honey-bees sucking the juice from injured fruits.

No. 8.—THE NIGHT-FLOWERING CATCHFLY.—The blossoms of the Pink family are extremely interesting. There are 10 stems. The flowers open after sun-down, when they are white and conspicuous, but soon fade, and during the first evening of the three in which each flower expands, five of the anthers are pushed out of the flower-tube and shed their pollen; after which the petal curls up and falls away. The next morning the petals curl up and present the appearance of a faded flower. During the day these flowers curl, but in the evening the petals again unfold, the scent returns, and the other five anthers appear. It is not until the third evening, when all the pollen is exhausted, that the petals curl up and exposes itself to receive pollen from other flowers.

Several other charts of a similar nature to the above were shown, and their bearing on the subject explained. In bringing his remarks to a close, Mr. Fletcher spoke of the great value to all classes of workers of the introduction of “Nature Study” into our schools and universities. He spoke highly of the work which had been done by Prof. Bailey and Craig of Cornell University. He knew of nothing so valuable in education as inciting a child to take a logical and scientific approach to all knowledge, concerning all the common objects which surround us on every side, an ignorance of which in most classes of the common school is such a conspicuous characteristic.

(Continued next week.)

Contributed Articles.

Selling Comb Honey by the Case.

BY D. W. WORLING.

ACTING on the suggestion of the Editor of the American Bee Journal, I read before the Colorado State Bee-keepers’ Association a proof of the article by R. A. Burnett & Co., published on page 759. This article, which seems to have been written especially for the encouragement of Colorado beekeepers, was discussed at some length by our members; and I venture to offer an abstract of their remarks.

Mr. Frank Rauchfuss, manager of the Colorado Honey-Products Association, said:

I pleased to inform one of the letters quoted in this article. If we guarantee a weight for separated, half-separated, and unseparated honey, is it not the same thing as selling by weight? In one of Burnett & Co.’s letters to us, they said they were not willing to buy an unknown quantity. I wrote back that they were buying a known quantity. In one instance the buyers got 200 pounds more than they were figuring on. It is an injury and an imposition to make the statements in that article without stating the whole thing. A house of that standing should know something of the difference between separated and unseparated honey. They want to sell 200 pounds of honey; and as soon as concessions are reached they will throw out the heavy-weight honey. It has worked that way, and it will work that way again.

R. C. Alikin—Our system is perfectly fair. It guards against wrong-doing on both sides.

H. C. Morrooke—It fully endorses those remarks. The article misrepresents the position of our people.

T. Lytle—When the buyer asks for quotations by the case, he makes a bid on the guaranteed weight. He is not injury, and is not unfair to the producer.

Mr. Alikin—Selling by the case makes it an easier matter to do business. We have rules to sell by.

Mr. Rauchfuss—None of the grading rules but ours have considered the question of weight. We have a standard section, which they do not have. I think this is a standard section, we can have a standard of weight. How can you adopt a set of rules, with a standard section, without taking weight into consideration? I can show quantities of honey in our store now, graded as No. 2 under our rules, which will be sold as No. 1 in Eastern markets. Selling by
American cases does have pack-
tions, discussion well rule must
weight. articles mentions weight
we would if it were not for those-
rules.
Mr. Rauchfuss—When honey is sold by weight only, no
distinction is made between separated and unseparated
honey. But by our rules we admit that half-separated and un-
separated honey are less desirable than separated, which is
easier to lift out without damage, by the grocer. By our
system, there is more uniformity of weights. We

guarantee weights, and give a man every pound he

says.
The attentive reader will have noticed that the foregoing
discussion is based on a Colorado grading system rather than a
criticism of the article by Burnett & Co. This is for the
Our people are familiar with the merits of their own methods;
you could not be perfectly sure of the merits of the
arguments favoring another system by a single hearing of such an
article as this to read them.

Burnett & Co. could not well be ignorant of the Colorado
grading rules. These rules have been published in the
American Bee Journal. A copy has been furnished to Burnett &
Co. and they are anxious to understand them. In spite of the knowledge which they
must have had to the contrary, they beg the whole question by
referring to the, "pig in the bag." Let me quote the Colorado
rule for No. 1 honey:

No. 1—Sections to be well filled and capped, honey white, slightly
and uniformly viscous, pollen-free, and projecting beyond the
well cleaned; cases of separated honey to average 24 pounds net
per case of 24 sections, with a minimum weight of not less
than 230 pounds net per case of 24 sections, with a minimum
weight of 20\% pounds for any single case; cases of unseparated
honey to average at least 20\% pounds net per case of 24
sections, with a minimum weight of 21\% pounds for any single case.

Will any intelligent reader of the American Bee Journal believe
that the man who buys honey guaranteed to be packed
according to that rule is buying a pig in a bag? Indeed, will
the man who does not know that the buyer, whether of one case or
card of cases, is sure to get at least a certain, definite
amount of honey?
The argument in which the "bag of tea, coffee or sugar"
figure does not lack ingenuity. But why did not this wise
logician conclude that the bag had no contents? Does it weigh
exactly a hundred pounds? Not at all. And yet flour is
quoted by the hundred-weight. We buy a great variety of
articles by the package. And the grocer who sells a section of
honey as a pound is probably giving as much weight for the
money as he does when he sells certain other "pound" pack-
ages. People who buy honey by the section can easily be
made to understand that sections are very likely to vary in
weight. Can it be that any one is so lacking in discernment as
to suppose that every section (pound section, if you please)
would be equal in weight to every other section?
Perhaps I am inexcessably ignorant; but I must confess
that I do not know of a single association of bee-keepers that is
willing to accept the ready-made, out-and-out standards I am
sure our rules make it necessary to have the scales pretty
close by when packing comb honey—as the readers can

but I am sure the rules of the Colorado State Association can not
be fairly interpreted to the hurt of the buyer. He is
sure to get at least a certain weight, but if that is
exceeded, no one will complain. Of course, there are indivi-
dual bee-keepers who can not or will not grade honestly. I
am not defending them.

Arapahoe Co., Colo.

Apriary Inspection in the State of Michigan.

To the Honorable Dairy and Food Commissioner:

Sir:—I herewith submit my report for the work done during the
months of July, August, September and October as State Inspector of Apriarys.
I have visited in the field 1,256 apiarys, in the State of Michigan,
definitely inspecting in them a total of 3,256 colonies. I have found
402 diseased colonies, making a total of 12.1 percent of those
inspected. I have found the disease present in 112 apiarys,
which is 57.7 percent of the whole number inspected. It will
be noticed that the majority of the yards that contained the
disease have in them only a few, and many times only one
colony. It is impossible to tell exactly how many of the dis-
cased colonies have been destroyed by the owner. Perhaps
50 percent of those condemned. I have been compelled to burn
only one colony against the will of the owner. These apiarys
were scattered throughout the counties of St. Joseph, Hillsdale,
Lenawee, Washtenaw, Jackson, Calhoun, Barry, Eaton, In-
gham, Livingston, Oakland, Macomb, St. Clair, Lapeer, Gene-
vanee, Clermont, Ingham, Muskegon, Montcalm, New-
ford, Benzie, Kalkaska and Altrim.

I have found the disease more prevalent in the older sec-
tions of country, that is, there is more disease in southern and
central Michigan than in the northern parts of the State.
In the north it is confined to localities, and is not of very long
standing. In almost every case it can be traced back to
the bringing in of diseased bees or fixtures from the south.
In the southern part, however, the disease is scattered promiscu-
ously and breaks out in yards, infecting many colonies, with-
out any source of contamination.

I have found many bee-keepers who are perfectly ignorant
of the disease, and even when it is present in their yards and
a large proportion of their bees are diseased, they fail to see
the symptoms of the disease. But it is the duty of the bee-keepers
of a bee-keeper to the class who keep a few bees as a side-issue, and are
not posted in modern apiculture. Then, again, I have found
the disease present in the apiarys of specialists in bee-culture,
who are unfortunate enough to be located in the same vicinity
with one of these bee-keepers who are not posted. The unin-
formed man will not listen to the advice and pleadings of the
specialist, but will leave diseased colonies to die, and be rob-
bbed out by the bees from the larger yard. In this way the disease
will spread from one locality to another, until the bee-keeper
cannot control the action of his ignorant neighbor. Then, oftentimes, when this speciali-
ist resorts to the protection of the law to compel his neighbor
to clean up the diseased yard, he is looked upon by the people
as this villain.

The most active agents in spreading the disease are, first,
that of robbing out colonies which have become weak and run
down; and, second, that of using old hives in which the bees
have died from the disease.

A grave difficulty arises when treating the bees to over-
come foul brood, in that it is a very hard matter to impress
the uneducated man with the necessity of careful work, and
the nature of bacteria. He will neglect some small but impor-
tant matter, or fail to take some necessary precaution in or-
der to insure success. As a consequence, the treatment is
 failures, and the disease will spread from one locality to another;
many apiarists are eager to learn all that is to be known about
the disease, and by careful, persistent work have stamped it
out of their yards. The treatment used by many apiarists has
been to kill the infected colony with sulphur, remove the hive
to the cellar, and cut out and save for home use all good honey,
scape clean and disinfect the hive, finally burning all refuse,
scrapping and inside furniture. This method of treatment en-
thals much less work than attempting to cure the colony, and
the honey and also the hive is saved.

The needs are great, and many localities where the disease
is known to exist have not been visited at all. Many of the
localities visited this summer must be covered again at the be-
ginning of next season, but I believe that there is no disease
in the State. I have met with the most hearty co-operation on
the part of the intelligent apiarists of the State. They have
not only manifested an interest in the work, but in many cases
have materially assisted in the propagation of the disease
in their locality. Respectfully submitted.

John M. Rankin.

(End of Document)
Report for 1901—Sweet Clover and Alfalfa.

By W. M. STOLLEY.

Like most of the readers of the American Bee Journal, I also will make my annual report, as usual.

Although drought-striken as was the entire West, the past season, the great value of sweet clover and alfalfa as forage-plants for honey-yielding bees is again clearly proven, by the crops of hay and honey I harvested.

Regarding the product of my apiary, my report is as follows:

From 21 colonies ran for extracted honey, I got 3105 pounds, or an average of about 148 pounds per colony. From 5 colonies in New Heddon hives run for comb honey, I got 380 well-filled and perfectly capped sections, or an average of 76 pounds of honey per colony, and, besides, 60 pounds of extracted honey. I thus got a total of 3945 pounds of surplus honey from 26 colonies of bees, spring count, and plenty for the bees for winter on beyond.

I had but 5 swarms, all told. My best colony ran for extracted honey of these 5 pounds of surplus, and my best colony ran for comb honey gave me 136 sections and 12 pounds of extracted. I got 46 pounds of bright yellow wax from cappings, and reared 19 extra-fine queens from my choicest colonies for my own use; and increased, by the nucleus plan, from 26 to 35 colonies. Ever since October 18, my bees have been packed for winter, and had a general flight to-day (Nov. 12.) But I sustained quite a loss, in the past season, as the surplus combs are not yet exchanged for the purchase of 5 queens in the late summer of 1900. The queens I got were reported as of extraordinary value, and a remarkably superior strain. When these queens arrived, they proved to be undersized; but I did not scare me, because I have seen many a small queen which was much the superior of larger queens.

But when one of those queens proved herself to be a most miserable hybrid, my confidence in this extra ‘superior strain’ was greatly shaken, and with considerable apprehension as to the value and worth of the other four, I waited results after wintering them.

The hybrid queen was replaced by another queen, and was introduced as late as October 12, 1900. In the spring following, three queens of that ‘superior strain’ of bees proved to be practically worthless, and very poor layers, which I consider a most unusual circumstance. Only the one I received in October, to take the place of the little black hybrid, proved to be a really fine queen, and her colony is one of the very best in my apiary.

Two of the queens, which I bought as superior stock, I killed in early summer, and united their colonies with the colony of the queen that was lacking, to give her a trial in the season.

The united colonies of this ‘superior strain’ did not average in strength with any one of my ordinary colonies, after forming but one colony. The united colonies, if their queen had been all right, would have given me about 450 pounds of surplus extracted honey for the season that I removed them from the manes or let them go.

While the three united colonies of this ‘superior strain’ have actually given me only 43 pounds surplus! Hence, I actually lost about 400 pounds of honey, in consequence of the death of the $25.00, a loss of $90, since I sell my honey at $5 cents per pound.

I have but a small apiary, but I aim to have a superior queen in every hive, and if any one of them is lacking, she has to make room for some other, and I aim well.

Some 18 or 19 years ago a Mr. Briggs, of Iowa, (if I remember the location rightly) made, in substance, the following proposition in the American Bee Journal, to breeders of queens generally.

Rev. Briggs (as Briggs) will pay $100 for the queen sent me by any queen-breeder, upon the following conditions, to wit:—

1.—All queens entrusted to me by any party, will receive at my hands, the very best care and attention, and an accurate record of their work will be kept.

2.—At a certain date (stated) a disinterested committee (here the widely known parties comprising that committee were named) will be the judges in the contest, and the party whose queen is declared to be the premium queen will get the $100, but the queen thus awarded becomes my (Rev. Briggs) property.

3.—I (Rev. Briggs) also reserve the right, while making this offer, to retain any and all the queens sent me, upon the payment of $2 for each queen retained by me, and I will renounce all queens not wanted by me, free of charge, if so desired by the party or parties sending me queens.

Now, I do not remember the name of the party whose queen won the $100, but I ordered one of the queens reared in the following year from the $100 queen by Rev. Briggs, and paid $5 for that queen, and it was the cheapest and best queen I ever bought.

Fifteen of the 36 queens now in my apiary are ‘Briggs queens,’ and they are in the lead as mothers of honey-producers.

I have other valuable strains of bees, obtained from other dealers in queen-bees, but the ‘Briggs strain’ proves, best of all, that ‘blood will tell.’

Now, Mr. Editor, I wish that another Rev. Briggs, as honest and reliable as was the one I have mentioned above, would work a similar scheme, and I, for one, will cheerfully pay $5 for one of the offspring of such queens reared ‘in a natural way’: but I want the bees to rear the queens under the most favorable conditions: and consider that the superior of queen-cells from bottom to top, too. No stick-made queen-cups for any queens that I wish to introduce into any colony in my apiary.

I shall with great interest the proceedings of the meeting at Buffalo, and always ‘reach out at once’ for the ‘Old Reliable’ when it comes.

Hall Co., Neb.

The Afterthought.

'The Old Reliable' seen through New and Unreliable Classes.

By E. E. HASTY, Sta. B Rural, Toledo, O.

TIME OF QUEEN EMERGENCE.

Yes, siree, Dr. Miller, if it's true with regularity, or anything like regularity, that queens emerge in full colonies in 15 days, and only in nuclei or other depressing circumstances take 16 days, then that venerable (not sweet) 16 would come out of the way. But let us not be partial. We can hardly expect the superior of queen-cells from bottom to top, too. No stick-made queen-cups for any queens that I wish to introduce into any colony when I get the 'Old Reliable.'

Swarms and Full Sheets of Comb Foundation.

Sounds reasonable that a swarm might consider sheets of foundation simply as partitions, and object to so many ridiculously narrow rooms. But a good many swarms have been successfully hived on full sheets, I take it. Page 586.

Six Honey Crops in Twelve.

Six paying crops in twelve years, as an actual experience, rather takes us down in our estimate of bee-keeping in the irrigation regions. Queens of bees can hardly be as good as six out of twelve unless there is something else besides alfalfa to prop up with. Page 595.

That Unfortunate Glucose-Feeding.

Once more I will refer you to that ton of glucose on pages 579, 681 and 707. I supposed that it marked another milestone on a road that we would prefer fenced up—or rather never graded out. It used to be the case that pure glucose would only be taken when bees were in a state of semi-starvation, and that they would stop taking it as soon as they had a rather small supply—never building comb and storing surplus with it.

When I read of so large an amount as a ton I feared that improvements of the article had changed some if not all of this. Glad if we don't have to believe so just yet. I must cry for mercy as to the dull way I read the editorial. The time of year forbids the idea of fraudulent surplus. We do not know that he succeeded in feeding it all, and to work out what he fed he may have mixed it with something better.

Starvation for Black Brood.

That was a wise remark of McEvoy's on the black-brood question, page 710. Imprinting bees off the combs for four days without feeding uses up the infected honey all right—so far, well: but it also gets the bees themselves into such a lean and inactive condition as they must not be in if they are to combat disease to advantage: and it takes days to get them out of that condition. So it is in doubt whether that particular manipulation does more good than harm, or more harm than good.
CONVENTION NOTICES.

Wisconsin—The Wisconsin State Bee-Keepers' Association will hold its usual convention in the State Capitol, at Madison, Feb. 3 and 4, 1922, when there will be a large conference of the fraternity. All are invited to attend. There will be excursions to the best local beehives, and a program of lectures and discussions. The second day will be a day of work, and the afternoon will be devoted to the election of officers.

Michigan—The Michigan State Bee-Keepers' Association meet in the city of Battle Creek, Michigan, Jan. 1 and 2, 1922. This promises to be one of the most largely attended meeting of the Association. A number of new members are to be admitted, and a number of the best beehives in the state will be visited. The Association will hold its annual convention on the Chamber of Commerce, Los Angeles, Jan. 15 and 16, 1922. We will try to have a good program. Come and exchange your bright ideas with your neighbors, and get some of the most raised off year. J. F. McLinney, Sec., G. & S. STURGEON, President.

1901—Bee-Keepers' Supplies.

We can furnish you with the A. I. Root Co's goods at wholesale or retail at their prices. We can save you freight, and ship promptly. Market price paid for bee-yards. Send for our list.

California—The California State Bee-Keepers' Association will hold its annual convention in the Chamber of Commerce, Los Angeles, Jan. 15 and 16, 1922. We will try to have a good program. Come and exchange your bright ideas with your neighbors, and get some of the most raised off year. J. F. McLinney, Sec., G. & S. STURGEON, President.

OUR NEW CATALOG, describing and listing the FINEST LINE OF BEE-KEEPERS' SUPPLIES IN THE WORLD, will be ready about the first of the year. If you have not already received a copy annually, send your name and address and we will mail you one. Prices will be same as last season. In addition to the regular plate sections with no bee ways, will be 25 cents per thousand less.

G. B. LEWIS COMPANY, Watertown, Wis., U. S. A.

Excellent shipping facilities and very low freight rates for Southern and Eastern territories.

A HANDY TOOL-HOLDER!

Every Manufacturer, Miller, Carpenter, Cabinet Maker, Machinist, Wheelwright and Quartermaster, Farmer, or anyone using a grind-stone, should have one of these Tool-Holders. One boy can do the work of two persons, and grind much faster, easier, and with perfect accuracy. Will hold any kind of tool, from the smallest chisel to a draw shaft or ax. Extra attachment for sharpening secythe blades included in the above price. The work is done without wetting the hands or spoiling the clothes, as the water flows from the operator. It can be attached to any size stone for hand or steam power, is always ready for use, without the exception of the narrow, plate sections, and is absolutely worth 100 times its cost.

How to Use the Holder.

DIRECTIONS.—The Tool is fastened securely in the Holder by a set-screw and can be ground to any desired bevel by inserting the arbor of the Holder into a higher or lower inch of the stone. While turning the tool against the right hand, hold with the left on the stone, which is operated by the right hand, just as you would hold a file in using a draw-shaft or draw-ax.

For grinding Round-Edge Tools, the tool is used instead of the holder.

The "Barler Ideal" OIL-HEATER....

Saves Its Cost Every Year! NO ODOUR! NO SMOKE! NO ASHES! Costs only a cent an hour to run it.

The editor of the American Bee Journal is using the "Barler Ideal" Oil Heater, and it is all right in every way. We liked it so well that we wanted our readers to have it too, so we have recently arranged with its manufacturers to fill our orders. The picture shown herewith is the one we recommend for general use. It is a perfect gem of a store for heating dining-rooms, bed-rooms, and bath-rooms. It hangs back in a substantial way, and is thoroughly well made through. The urn removes for heating water. The brass front, with bell, has a bail, and it weighs one little gallon of kerosene oil. It is just as safe as an ordinary lamp. You would not be without it for twice its cost, after once having one of these stoves. Most oil-stoves emit an offensive odor, but this one doesn't. Its height is 3½ feet, and weighs 20 pounds, or 20 pounds crated ready for shipment, either by freight or express.

Price, F.o.b. Chicago, $8.00; or, combined with a year's subscription to the American Bee Journal—both for only $10.00. FULL DIRECTIONS go with each stove.

If you want something that is really serviceable, reliable, and thoroughly comfortable, you should get this "Barler Ideal" Oil Stove, as it can easily be carried by any woman from one room to another, and thus have all the heat you want right where you want it.

The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son.

Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped in the way to success with bees.

The book we mail for $1.25, or club it with the American Bee Journal for one year—both for $1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with $3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.

A New Bee-Keeper's Song—
"Buckwheat Cakes and Honey"
Words by EUGENE SECOR.
Music by GEORGE W. YORK.

This song was written specially for the Buffalo convention, and was sung there. It is written for organ or piano, as it has been all the songs written for bee-keepers. Every home should have a copy of it, as well as a copy of "THE HUM OF THE BEES in the APPLE-TREE BLOOM"

Written by EUGENE SECOR and Dr. C. C. MILLER.

Prices—Either song will be mailed for 10 cents (stamps or silver), or both for only 15 cents. The above is strictly in advance payment of a year's subscription to the American Bee Journal, we will mail both of these songs free, if asked for.

144 & 146 Erie St., - CHICAGO, ILL.
The AMERICAN or United States Map on China, Cuba, Porto Rico, The Philippines, Hawaii, and Alaska, especially prepared to meet the demand for a first-class map that will give a quick, general idea of location of events the world over, and particularly to the United States and our territorial possessions. Very useful in every Home and Office. 66 x 46 INCHES IN SIZE.

ELEVEN BEAUTIFUL COLORS.

Best and Most Necessary Map Ever Issued.

No Home or Business House should be without it.

The Plates are works of art. The engraving is plain, bold, and decisive. The color work is elegantly contrasted, but not gaudy.

Perfection and Artistic Elegance a salient feature of this map not approached by any similar publication.

The 1900 Census of the largest American Cities is given.

It has been pronounced a Photograph of the World

Two maps forward it free as a premium for sending us Three New Subscribers at $1.00 each; or for $2.00 we will send the Map and the American Bee Journal for one year.

ADDRESS:

GEORGE W YORK & CO.,
144 & 146 Erie Street, CHICAGO, ILL.

The 1901 Edition—Every reader should to suit it every day. The plates show all the fine railroad lines and extensions, county changes, etc. Special attention is given to the geography of the country; all the principal rivers and lakes, mountain ranges and peaks are plainly indicated. The leading cities and towns are shown, special attention being given to those along lines of railroads. The Canadian portion of the map gives the provinces of Ontario, Manitoba, and British Columbia, with nearly all of Quebec and New Brunswick, the county divisions being clearly marked. The Southern portion of the map includes the Northern States of the Republic of Mexico, and the Bahamas, on the reverse side is the Library Map of the World. The largest and most accurate map on Mercator’s Projection ever produced. The political divisions are correctly defined and beautifully outlined in colors. The ocean currents are clearly shown and named. Ocean steamship lines with distances between important ports are given. A marginal index of letters and figures enables one easily to locate every country in the world. A series of short articles in alphabetical order is printed around the border of this map in large, clear type, containing valuable information concerning agricultural, mining, and manufacturing statistics, also the value of imports and exports in dollars. The area, population, form of government, and chief executive of every country in the world is given up to date, also the names of the capitals and their population. The Inset Maps are elegantly engraved and printed in colors. They are placed in convenient positions around the United States map, and will be invaluable to every person desiring a plain understanding of our possessions. An inset map of China on the World side of map adds to its value.
Change of Chicago Passenger Station.

Beginning December 29, all passenger trains of the Nickel Plate Road will arrive and depart from Grand Central Station, 222 W. Washington St., Chicago, instead of Van Buren St. Station, as formerly. 49-52A1

HONEY AND BEEWAX

MARKET QUOTATIONS

CHICAGO, Dec. 19—The honey market is of a stability that is peculiar to itself, having little of the gaiety. At the close of last week the dealers had much work to do, and were active in carrying it to the market to meet the heavy demand. Choice grades of white comb honey range 10 $1.45 good to No. 1, 1.60 bright and 1.80 red, and overstocked, including buckwheat, 10 $1.95. Extracted, white, $1.45; buff, $1.85; buckwheat, 10 $1.20. Extracted honey, according to flavor and body, is in demand at various prices ranging from 25c.

R. A. HORNBY & CO.

NEW YORK, Dec. 19—Comb honey continues to be in good demand, and while the market is not overstocked, arrivals of white honey are not sufficiently large to meet the demand, while buckwheat is rather scarce. We quote: Fancy white, 10 $1.20; No. 1, 1.40; No. 2, 1.25; No. 3, 1.00; buckwheat, 10 $1.00; light amber, 10 $1.60; dark, 10 $1.85; Southern, 10 $2.00; foreign, 10 $3.00, at 25c.

HILDETH & SORLEHN.

CINCINNATI, Dec. 20—The honey market is rather dull, and the weather requires that extracted honey should be the order of the day. Extracted sells only to manufacturers. Fancy grades sell all the way from 80c. to 60c. per lb. Retail prices vary according to flavor and body, and range from 10 60c. to 10 25c. C. C. & W. WEBER.

ALBANY, N. Y., Dec. 20—Honey in good demand now, as this is the most satisfactory time for Grocers. In the up country there will be and will buy large quantities, when late this year they can buy in 10 60c. to 10 75c. piece to piece. Fancy white comb, 60c.; mixed, 60c.; buckwheat, 10 75c. to 10 95c.; light amber, 10 80c. to 10 95c.; dark amber, 10 90c. to 10 60c.; H. R. WRIGHT.

OMAHA, Dec. 20—New comb honey is arriving by express from small production, and we predict that Colorado and New Mexico and Oklahoma, shipment (attracts) with us at the 22.50 price. California imported honey is being offered to the north in increased quantities as the Florida shipping points, but we have not heard of any comb honey being produced. The production of extracted honey seems to be quite large this year in Colorado, Utah and Nevada.

PECK & BRORS.

BOSTON, Dec. 20—The demand for honey is easing up somewhat, due in part to the holiday season and to the heavy immediate harvest. Our market at the present time ranks for sweets of quality in fancy categories. We quote: Buckwheat, 10 50c.; amber, 10 60c.; light amber, 10 85c.; dark amber, 10 95c.

R. A. BURNE & CO.

CHICAGO, 31Aff.

Wanted—Honey. Car Lots or otherwise; will pay highest market price, spot cash. Address, stating quately, and price desired at your station. Will send man to receive when lot is large enough to justify. THOS. C. STANLEY & SONS, 31Aff.

THE NICKEL PLATE ROAD will sell tickets Dec. 24, 25 and 31, 1901, and Jan. 1, 1902, for the ‘Buckeye State Fair’ and a third for the round-trip to any point located in Central Passenger Association territory, according to Christmas and New Year Holidays. Return tickets include Jan. 2, 1902. Through service to New York City, Boston, and other Eastern points. Chicago Passenger Station, 111 W. Washington St., or ticket office, on the Elevated Loop. For further information address John Y. Calahan, General Agent, 111 Adams St., Chicago.

Send for circulars regarding ourImproved and original Winterbloom Bee-Boxer For 23 YEARS THE BEST ON EARTH.

T. F. BINGHAM, Farwell, Mich.
In order to accommodate the largely increased passenger business at Chicago Van Buren Street Depot, it has been found necessary to build a new and more commodious passenger station. Therefore, commencing December 29, all passenger trains of the Nickel Plate Road will arrive at and depart from Grand Central Station, 5th Ave. and Harrison St., during the erection of the new depot. 50-52A1

**Texas Bee-Keepers.**

New Branch Office. We beg to announce the opening of a branch office and warehouse at 438 W. Houston St., San Antonio, Texas. Rates of transportation from Medina in less than car-load lots are high, and it takes a long time for a local shipment to reach Southern Texas points.

Low Freight and Quick Delivery, San Antonio as a Shipping-point.

To secure these two necessary advantages—low freight and quick delivery—and to be better prepared to serve the interests of our Texas friends, our reason for establishing this new branch office. No other point in Southern Texas is better adapted to serve as a distributing point than San Antonio. It has four great railroads—the Southern Pacific R. R. east and West—the International and Great Northern R. R. from Laredo up through San Antonio and Central Texas, the San Antonio and Arkansas Pass R. R., and San Antonio and Gulf R. R. It also has the American, Wells-Fargo and Pacific Express Companies.

Our Managers. We have secured as managers Mr. Udo Toepperwein, formerly of Leon Springs, and Mr. A. Y. Walton, both of whom are well known to the bee-keepers of South and Central Texas. They are also thoroughly familiar with practical bee-keeping and all matters associated with it, and any orders sent to this branch will receive prompt, careful attention.

Our Goods. As usual our motto is to furnish the best goods of the most approved pattern. We do not undertake to compete in price with all manufacturers. Bee-keepers have learned that it does not pay to buy cheap supplies, for a saving of ten cents on the first cost of a hive may be a loss of many times this amount by getting poorly made and ill-fitting material. Every year brings us many proofs that our policy of "the best goods" is a correct one.

Our Catalog. Very few changes in prices will be made in our new catalog, so do not delay your order but send it at once. You will be allowed a refund if lower prices are made, and in case of higher prices ruling in the new catalog, if any, you will secure the benefit by ordering now. Catalog and estimates may be had by applying to the address given below.

Our Invitation. Whenever you visit San Antonio you are invited to call at our office and make it your headquarters. Here you will find a display of Apiarian Supplies not expalined elsewhere in Texas. You will also find on file the leading bee-journals to pass pleasantly your leisure time.

Spanish Catalog. Some of you may read Spanish, or have a bee-keeping friend who does. If so, call for our Spanish catalog. It's sent free.
